SUPPLEMENT

TO THE THIRD EDITION OF THE

ENCYCLOPÆDIA BRITANNICA,

OR

DICTIONARY

OF

ARTS, SCIENCES,

AND

MISCELLANEOUS LITERATURE.

IN TWO VOLUMES.

Illustrated with Fifty Copperplates.

By GEORGE GLEIG, LL. D. F. R. S. Edin.

NON IGNORO, QUÆ BONA SINT, FIERI MELIORA POSSE DOCTRINA, ET QUÆ NON OPTIMA, ALIQUO MODO ACUI TAMEN, ET CORRIGI POSSE.—*Cicero.*

VOL. II

Edinburgh:
PRINTED FOR THOMSON BONAR, PARLIAMENT-SQUARE,
BY *JOHN BROWN*, ANCHOR CLOSE, EDINBURGH.

1801.

[Entered in Stationers Hall.]

SUPPLEMENT

TO THE

ENCYCLOPÆDIA BRITANNICA.

Increment, Indeterminate.

INCREMENT, is the ſmall increaſe of a variable quantity. Newton, in his Treatiſe on Fluxions, calls theſe by the name *Moments;* and obſerves, that they are proportional to the velocity or rate of increaſe of the flowing or variable quantities in an indefinitely ſmall time. He denotes them by ſubjoining a cypher o to the flowing quantity whoſe moment or increment it is; thus, xo the moment of x. In the doctrine of Increments, by Dr Brooke Taylor and Mr Emerſon, they are denoted by points below the variable quantities; as $\underset{.}{x}$. Some have alſo denoted them by accents underneath the letter, as $\underset{'}{x}$; but it is now more uſual to expreſs them by accents over the ſame letter; as x'.

METHOD OF INCREMENTS, a branch of Analytics, in which a calculus is founded on the properties of the ſucceſſive values of variable quantities, and their differences or increments.

The inventor of the method of increments was the learned Dr Taylor, who, in the year 1715, publiſhed a treatiſe upon it; and afterwards gave ſome farther account and explication of it in the Philoſ. Tranſ. as applied to the finding of the ſums of ſeries. And another ingenious and eaſy treatiſe on the ſame, was publiſhed by Mr Emerſon, in the year 1763. The method is nearly allied to Newton's Doctrine of Fluxions, and ariſes out of it. Alſo the Differential method of Mr Stirling, which he applies to the ſummation and interpolation of ſeries, is of the ſame nature as the method of increments, but not ſo general and extenſive.

INDETERMINATE PROBLEM. See ALGEBRA, Part I Chap VI. *Encycl.*

Diophantus was the firſt writer on indeterminate problems, which, after the publication of his work in 1621 by Bachet, employed much of the time of the moſt celebrated mathematicians in Europe. Afterwards ſuch problems were neglected as uſeleſs, till the public attention was again drawn to them by Euler and la Grange. The example of ſuch men was followed by Mr John Leſlie, a very eminent and ſelf-taught mathematician; who, in the ſecond vol. of the Tranſactions of the Royal Society of Edinburgh, has publiſhed an ingenious paper on indeterminate problems, reſolving them by a new and general principle. "The doctrine of indeterminate equations (ſays Mr Leſlie) has been ſeldom treated in a form equally ſyſtematic with the other parts of algebra. The ſolutions commonly given are devoid of uniformity, and often require a variety of aſſumptions. The object of this paper is to reſolve the complicated expreſſions which we obtain in the ſolution of indeterminate problems, into ſimple equations, and to do ſo, without framing a number of aſſumptions, by help of a ſingle principle, which, though extremely ſimple, admits of a very extenſive application.

Indeterminate, Induction.

"Let $A \times B$ be any compound quantity equal to another, $C \times D$, and let m be any rational number aſſumed at pleaſure; it is manifeſt that, taking equimultiples, $A \times m\,B = C \times m\,D$. If, therefore, we ſuppoſe that $A = mD$, it muſt follow that $mB = C$, or $B = \frac{C}{m}$. Thus two equations of a lower dimenſion are obtained. If theſe be capable of farther decompoſition, we may aſſume the multiples n and p, and form four equations ſtill more ſimple. By the repeated application of this principle, an higher equation, admitting of diviſors, will be reſolved into thoſe of the firſt order, the number of which will be one greater than that of the multiples aſſumed."

For example, reſuming the problem at firſt given, viz. to find two rational numbers, the difference of the ſquares of which ſhall be a given number. Let the given number be the product of a and b; then by hypotheſis, $x^2 - y^2 = ab$; but theſe compound quantities admit of an eaſy reſolution, for $\overline{x+y} \times \overline{x-y} = a \times b$. If, therefore, we ſuppoſe $x + y = ma$, we ſhall obtain $x - y = \frac{b}{m}$; where m is arbitrary, and if rational, x and y muſt alſo be rational. Hence the reſolution of theſe two equations gives the values of x and y, the numbers ſought, in terms of m; viz.

$$x = \frac{m^2a + b}{2m}, \text{ and } y = \frac{m^2a - b}{2m}.$$

INDUCTION, in logic, is that proceſs of the underſtanding by which from a number of *particular* truths perceived by ſimple apprehenſion, and diligently compared together, we infer another truth which is always *general* and ſometimes *univerſal.* It is perhaps needleſs to obſerve, that in the proceſs of induction the truths to be compared muſt be of the ſame kind, or relate to objects having a ſimilar nature; for the mereſt tyro in ſcience

Induction. science knows that physical truths cannot be compared with moral truths, nor the truths of pure mathematics with either.

That the method of induction is a just logic, has been sufficiently evinced elsewhere (see LOGIC, Part III. chap. V. and PHILOSOPHY, n° 73—78. *Encycl.*), and is now indeed generally admitted. It is even admitted by British philosophers to be the only method of reasoning by which any progress can be made in the physical sciences; for the laws of Nature can be discovered only by accurate experiments, and by carefully noting the agreements and the differences, however minute, which are thus found among the phenomena apparently similar. It is not, however, commonly said that *induction* is the method of reasoning employed by the mathematicians; and the writer of this article long thought, with others, that in pure geometry the reasoning is strictly *syllogistical*. Mature reflection, however, has led him to doubt, with Doctor Reid *, the truth of the generally received opinion, to doubt even whether by categorical syllogisms any thing whatever can be proved. the idolaters of Aristotle we are perfectly aware that this will appear an extravagant paradox; but to the votaries of truth, we do not despair of making it very evident, that for such doubts there is some foundation.

* Appendix to Vol. III of *Sketches of the History of Man.*

We are led into this disquisition to counteract, in some degree, what we think the pernicious tendency of the philosophy of Kant, which attempts have been lately made to introduce into this country. Of this philosophy we shall endeavour to give something like a distinct view in the proper place. It is sufficient to observe here, that it rests upon the hypothesis, that "we are in possession of certain notions *à priori*, which are absolutely *independent of all experience*, although the *objects of experience* correspond with them; and which are distinguished by *necessity* and strict *universality*." These innate and universal notions, Kant considers as a set of *categories*, from which is to be deduced all such knowledge as deserves the name of science; and he talks, of course, or at least his English translators represent him talking, with great contempt, of inductive reasoning, and substituting syllogistic demonstration in its stead.

As his categories are not familiar to our readers, we shall, in this place, examine syllogisms connected with the categories of Aristotle, which are at least more intelligible than those of Kant, and which, being likewise general notions, must, in argument, be managed in the same way. Now the fundamental axiom upon which every categorical syllogism rests, is the well known proposition, which affirms, that "whatever may be predicated of a whole *genus*, may be predicated of every *species* and of every *individual* comprehended under that genus." This is indeed an undoubted truth; but it cannot constitute a foundation for reasoning from the *genus* to the *species* or the *individual*; because we cannot possibly know what can be predicated of the *genus* till we know what can be predicated of all the *individuals* ranged under it. Indeed it is only by ascertaining, through the medium of induction, what can be predicated, and what not, of a number of individuals, that we come to form such notions as those of *genera* and *species*; and therefore, in a syllogism strictly categorical, the propositions, which constitute the *premises*, and are taken for granted, are those alone which are capable of proof; whilst the conclusion, which the logician pretends to demonstrate, must be evident to intuition or experience, otherwise the premises could not be known to be true. The analysis of a few syllogisms will make this apparent to every reader.

Dr Wallis, who, to an intimate acquaintance with the Aristotelian logic, added much mathematical and physical knowledge, gives the following syllogism as a perfect example of this mode of reasoning in the first figure, to which it is known that all the other figures may be reduced:—

> *Omne animal* est *sensu præditum.*
> *Socrates* est *animal.* Ergo
> *Socrates* est *sensu præditus.*

Here the proposition to be demonstrated is, that Socrates is endowed with sense; and the propositions assumed as self-evident truths, upon which the demonstration is to be built, are, that "every animal is endowed with sense;" and that "Socrates is an animal." But how comes the demonstrator to know that "every animal is endowed with sense?" To this question we are not aware of any answer which can be given, except this, that mankind have agreed to call every being, which they perceive to be endowed with sense, an *animal*. Let this, then, be supposed the true answer: the next question to be put to the demonstrator is, How he comes to know that *Socrates* is an *animal?* If we have answered the former question properly, or, in other words, if it be essential to this genus of beings to be endowed with sense, it is obvious that he can know that Socrates is an *animal* only by perceiving him to be *endowed with sense*; and therefore, in this syllogism, the proposition to be proved is the very first of the three of which the truth is perceived; and it is perceived intuitively, and not inferred from others by a process of reasoning.

Though there are ten categories and five predicables, there are but two kinds of categorical propositions, viz. Those in which the property or accident is predicated of the substance to which it belongs, and those in which the *genus* is predicated of the *species* or *individual*. Of the former kind is the proposition pretended to be proved by the syllogism which we have considered; of the latter, is that which is proved by the following:

> Quicquid sensu præditum, est animal.
> Socrates est sensu præditus. Ergo
> Socrates est animal.

That this is a categorical syllogism, legitimate in mode and figure, will be denied by no man who is not an absolute stranger to the very first principles of the Aristotelian logic; but it requires little attention indeed to perceive that it proves nothing. The imposition of names is a thing so perfectly arbitrary, that the being, or class of beings, which in Latin and English is called *animal*, is with equal propriety in Greek called ζωον, and in Hebrew נפש. To a native of Greece, therefore, and to an ancient Hebrew, the major proposition of this syllogism would have been wholly unintelligible; but had either of those persons been told by a man of known veracity, and acquainted with the Latin tongue, that every thing endowed with sense was, by the Romans, called *animal*, he would then have understood the proposition, admitted its truth without hesitation, and have henceforth

henceforth known that Socrates and Moses, and every thing else which he perceived to be endowed with sense, would at Rome be called *animal.* This knowledge, however, would not have rested upon demonstrative reasoning of any kind, but upon the credibility of his informer, and the intuitive evidence of his own senses.

It will perhaps be said, that the two syllogisms which we have examined are improper examples, because the truth to be proved by the former is self evident, whilst that which is meant to be established by the latter is merely verbal, and therefore arbitrary. But the following is liable to neither of these objections:

All animals are *mortal.*
Man is *an animal*; therefore
Man is *mortal.*

Here it would be proper to ask the demonstrator, upon what grounds he so confidently pronounces all animals to be mortal? The proposition is so far from expressing a self evident truth, that, previous to the entrance of sin and death into the world, the first man had surely no conception of mortality. He acquired the notion, however, by experience, when he saw the animals die in succession around him; and when he observed that no animal with which he was acquainted, not even his own son, escaped death, he would conclude that all animals, without exception, are mortal. This conclusion, however, could not be built upon syllogistic reasoning, nor yet upon intuition, but partly upon experience and partly on analogy. As far as his experience went, the proof, by induction, of the mortality of all animals was complete; but there are many animals in the ocean, and perhaps on the earth, which he never saw, and of whose mortality therefore he could affirm nothing but from analogy, *i. e.* from concluding, as the constitution of the human mind compels us to conclude, that Nature is uniform throughout the universe, and that similar causes, whether known or unknown, will, in similar circumstances, produce, at all times, similar effects. It is to be observed of this syllogism, as of the first which we have considered, that the proposition, which it pretends to demonstrate, is one of those truths known by experience, from which, by the process of induction, we infer the major of the premises to be true; and that therefore the reasoning, if reasoning it can be called, runs in a circle.

Yet by a concatenation of syllogisms have logicians pretended that a long series of important truths may be discovered and demonstrated; and even Wallis himself seems to think, that this is the instrument by which the mathematicians have deduced, from a few postulates, accurate definitions, and undeniable axioms, all the truths of their demonstrative science. Let us try the truth of this opinion by analysing some of Euclid's demonstrations.

In the short article PRINCIPLE (*Encycl.*), it has been shewn, that all our *first* truths are *particular*, and that it is by applying to them the rules of induction that we form general truths or axioms—even the axioms of pure geometry. As this science treats not of real external things, but merely of *ideas* or *conceptions*, the creatures of our minds, it is obvious, that its definitions may be perfectly accurate, the induction by which its axioms are formed complete, and therefore the axioms themselves *universal* propositions. The use of these axioms is merely to shorten the different processes of geometrical reasoning, and not, as has sometimes been absurdly supposed, to be made the *parents* or *causes* of *particular* truths. No truth, whether general or particular, can, in any sense of the word, be the cause of another truth. If it were not true that all individual figures, of whatever form, comprehending a portion of space equal to a portion comprehended by any other individual figure, whether of the same form with some of them, or of a form different from them all, are equal to one another, it would not be true that "things in *general*, which are equal to the same thing, or that magnitudes which coincide, or exactly fill the same space," are respectively equal to one another; and therefore the first and eight of Euclid's axioms would be false. So far are these axioms, or general truths, from being the parents of particular truths, that, as conceived by us, they may, with greater propriety, be termed their *offspring*. They are indeed nothing more than general expressions, comprehending all particular truths of the same kind. When a mathematical proposition therefore is enounced, if the terms, of which it is composed, or the figures of which a certain relation is predicated, can be brought together and immediately compared, no demonstration is necessary to point out its truth or falsehood. It is indeed intuitively perceived to be either comprehended under, or contrary to some known *axiom* of the science; but it has the evidence of truth or falsehood *in* itself, and not in *consequence* of that axiom. When the figures or symbols cannot be immediately compared together, it is then, and only then, that recourse is had to demonstration; which proceeds, not in a series of syllogisms, but by a process of ideal mensuration or induction. A figure or symbol is conceived, which may be compared with each of the principal figures or symbols, or, if that cannot be, with one of them, and then another, which may be compared with it, till through a series of well known intermediate relations, a comparison is made between the terms of the original proposition, of which the truth or falsehood is then perceived.

Thus in the 47th proposition of the first book of Euclid's Elements, the author proposes to demonstrate the equality between the square of the hypothenuse of a right angled triangle, and the sum of the squares described on the other two sides; but he does not proceed in the way of categorical syllogisms, by raising his demonstration on some universal truth relating to the *genus* of *squares*. On the contrary, he proceeds to *measure* the three squares of which he has affirmed a certain relation; but as they cannot be immediately compared together, he directs the largest of them to be divided into two parallelograms, according to a rule which he had formerly ascertained to be just; and as these parallelograms can, as little as the square of which they are the constituent parts, be compared with the squares of the other two sides of the triangle, he thinks of some intermediate figure which may be applied as a common measure to the squares and the parallelograms. Accordingly, having before found that a parallelogram, or square, is exactly double of a triangle standing on the same base and between the same parallels with it, he constructs triangles upon the same base, and between the same parallels with his parallelograms, and the squares of the sides containing the right angle of the original triangle; and finding, by a process formerly shewn to be just,

that the triangles on the bases of the parallelograms are precisely equal to the triangles on the bases of the squares, he perceives at once that the two parallelograms, of which the largest square is composed, must be equal to the sum of the two lesser squares; and the truth of the proposition is demonstrated.

In the course of this demonstration, there is not so much as one truth *inferred* from another by *syllogism*; but all are perceived in succession by a series of simple apprehensions. Euclid, indeed, after finding the triangle constructed on the base of one of the parallelograms to be equal to the triangle constructed on the base of one of the squares, introduces an *axiom*, and says, "but the doubles of equals are equal to one another; *therefore* the parallelogram is equal to the square." But if from this mode of expression any man conceive the axiom or universal truth to be the *cause* of the truth more particular, or suppose that the *latter* could not be apprehended without a *previous* knowledge of the former, he is a stranger to the nature of evidence, and to the process of *generalization*, by which axioms are formed.

If we examine the problems of this ancient geometrician, we shall find that the truth of them is proved by the very same means which he makes use of to point [illegible] the truth of his theorems. Thus, the first problem of his immortal work is, "to describe an equilateral triangle on a given finite straight line;" and not only is this to be done, but the method by which it is done must be such as can be shewn to be incontrovertible, [illegible] The sides of a triangle, however, cannot be applied to each other so as to be immediately compared; for they are conceived to be immoveable among themselves. A common measure, therefore, or something equivalent to a common measure, must be found, by which the triangle may be constructed, and the equality of its three sides afterwards evinced; and this equivalent Euclid finds in the *circle*.

By contemplating the properties of the circle, it was easy to perceive that all its *radii* must be equal to one another. He therefore directs two circles to be described from the opposite extremities of the given finite straight line, so as that it may be the radius of each of them; and from the point in which the circles intersect one another, he orders lines to be drawn to the extreme points of the given line, affirming that these three lines constitute an equilateral triangle. To convince his reader of the truth of this affirmation, he has only to put him in mind, that from the properties of the circle, the lines which he has drawn must be each equal to the given line, and of course all the three equal to one another; and this mutual equality is perceived by simple apprehension, and not inferred by syllogistic reasoning. Euclid, indeed, by introducing into the demonstration his first axiom, gives to it the form of a syllogism: but that syllogism proves nothing; for if the equality of the three sides of the triangle were not intuitively perceived in their position and the properties of the circle, the first axiom would itself be a falsehood. So true it is that categorical syllogisms have no place in geometrical reasoning; which is as strictly experimental and inductive as the reasoning employed in the various branches of physics.

But if this be so, how come the truths of pure geometry to be necessary, so that the contrary of any one of them is clearly perceived to be impossible; whilst physical truths are all contingent, so that there is not one of them of which the direct contrary may not easily be conceived?

That there is not one physical truth, of which the contrary may not be conceived, is not perhaps so certain as has generally been imagined; but admitting the fact to be as it has commonly been stated, the apparent difference between this class of truths and those of pure geometry, may be easily accounted for, without supposing that the former rests upon a kind of evidence totally different from that which supports the fabric of the latter.

The objects of pure geometry, as we have already observed, are the creatures of our own minds, which contain in them nothing concealed from our view. As the mathematician treats them merely as measurable quantities, he knows, with the utmost precision, upon what particular properties the relation affirmed to subsist between any two or more of them must absolutely depend; and he cannot possibly entertain a doubt but it will be found to have place among all quantities having the same properties, because it depends upon them, and upon them alone. His process of induction, therefore, by a series of ideal measurements, is always complete, and exhausts the subject; but in physical enquiries the case is widely different. The subjects which employ the physical enquirer are not his own ideas, and their various relations, but the properties, powers, and relations of the bodies which compose the universe; and of those bodies he knows neither the substance, internal structure, nor all the qualities: so that he can very seldom discover with certainty upon what particular property or properties the phenomena of the corporeal world, or the relations which subsist among different bodies, depend. He expects, indeed, with confidence, not inferior to that with which he admits a mathematical demonstration, that any corporeal phenomenon, which he has observed in certain circumstances, will be always observed in circumstances exactly similar; but the misfortune is, that he can very seldom be ascertained of this similarity. He does not know any one piece of matter *as it is in itself*; he cannot separate its various properties; and of course cannot attribute to any one property the effects or apparent effects which proceed exclusively from it. Indeed, the properties of bodies are so closely interwoven, that by human means they cannot be completely separated; and hence the most cautious investigator is apt to attribute to some one or two properties, an event which in reality results perhaps from many. (See PHILOSOPHY and PHYSICS, *Encycl.*) This the geometrician never does. He knows perfectly that the relation of equality which subsists between the three angles of a plain triangle and two right angles, depends not upon the size of the triangles, the matter of which they are conceived to be made, the particular place which they occupy in the universe, or upon any one circumstance whatever besides their triangularity, and the angles of their correlets being exactly right angles; and it is upon this power of discrimination which we have in the conceptions of pure geometry, and have not in the objects of physics, that the truths of the one science are perceived to be necessary, while those of the other appear to be contingent; though the mode of demonstration is the same

Inertia, Inflammation.

same in both, or at least equally removed from categorical syllogisms.

INERTIA. See Dynamics and Impulsion in this *Supplement*.

INFLAMMATION has been sufficiently explained in the *Encyclopædia*, and in the article Chemistry in this *Supplement*; but it cannot be improper, in this place, to give an account of some remarkable

Spontaneous Inflammations, which, as different substances, are liable to them, have been, and may again be, the cause of many and great misfortunes.

The spontaneous inflammation of essential oils, and that of some fat oils, when mixed with nitrous acid, are well known to philosophers; so also is that of powdered charcoal with the same acid (lately discovered by M. Proust), and those of phosphorus, of pyrophorus, and of fulminating gold. These substances are generally to be found only in the laboratories of chemists, who are perfectly well acquainted with the precautions which it is necessary to take to prevent the unhappy accidents which may be occasioned by them.

The burning of a store-house of sails, which happened at Brest in the year 1757, was caused by the spontaneous inflammation of some oiled cloths, which, after having been painted on one side, and dried in the sun, were stowed away while yet warm; as was shewn by subsequent experiments *.

* See *Memoires de l'Academie de Paris*, 1760.

Vegetables boiled in oil or fat, and left to themselves, after having been pressed, inflame in the open air. This inflammation always takes place when the vegetables retain a certain degree of humidity; if they are first thoroughly dried, they are reduced to ashes, without the appearance of flame. We owe the observation of these facts to MM. Saladin and Carette †.

The heaps of linen rags which are thrown together in paper manufactories, the preparation of which is hastened by means of fermentation, often take fire, if not carefully attended to.

The spontaneous inflammation of hay has been known for many centuries; by its means houses, barns, &c. have been often reduced to ashes. When the hay is laid up damp, the inflammation often happens; for the fermentation is then very great. This accident very seldom occurs to the first hay (according to the observation of M. de Bomare), but is much more common to the second; and if, through inattention, a piece of iron should be left in a stalk of hay in fermentation, the inflammation of that stalk is almost a certain consequence. Corn heaped up has also sometimes produced inflammations of this nature. Vanieri, in his *Prædium Rusticum*, says,

Quæ vero (gramina) nondum satis insolata recondens
Imprudens, subitis pariunt incendia flammis.

Dung also, under certain circumstances, inflames spontaneously.

In a paper, published in the *Repertory of Arts and Manufactures*, by the Rev. William Tooke, F. R. S. &c. we have the following remarkable instances of spontaneous inflammation. "A person of the name of Rude, an apothecary at Bautzen, had prepared a pyrophorus from rye-bran and alum. Not long after he had made the discovery, there broke out, in the next village of Nauslitz, a great fire, which did much mischief, and was said to have been occasioned by the treating of a sick cow in the cow-house. Mr Rude knew, that the countrymen were used to lay an application of parched rye-bran to their cattle curing the thick neck: he knew also, that alum and rye bran, by a proper process, yielded a pyrophorus; and now he wished to try whether parched rye bran alone would have the same effect. Accordingly, he roasted a quantity of rye-bran by the fire, till it had acquired the colour of roasted coffee. This roasted bran he wrapped up in a linen cloth; in the space of a few minutes there arose a strong smoke through the cloth, accompanied by a smell of burning. Not long afterwards the rag grew as black as tinder, and the bran, now become hot, fell through it on the ground in little balls. Mr Rude repeated the experiment at various times, and always with the same result. Who now will any longer doubt, that the frequency of fires in cow-houses, which in those parts are mostly wooden buildings, may not be occasioned by this common practice, of binding roasted bran about the necks of the cattle? The fire, after consuming the cattle and the shed, communicates itself to the adjoining buildings; great damage ensues; and the ignorant look for the cause in wilful and malicious firing, consequently in a capital crime."

The same author informs us, that in the spring of the year 1780, a fire was discovered on board a Russian frigate lying in the road of Cronstadt; which, if it had not been timely extinguished, would have endangered the whole fleet. After the severest scrutiny, no cause of the fire was to be found; and the matter was forced to remain without explanation, but with strong surmises of some wicked incendiary being at the bottom of it. In the month of August, in the same year, a fire broke out at the hemp-magazine at St Petersburgh, by which several hundred thousand poods ‡ of hemp and flax were consumed. The walls of the magazine are of brick, the floors of stone, and the rafters and covering of iron; it stands alone on an island in the Neva, on which, as well as on board the ships lying in the Neva, no fire is permitted. In St Petersburgh, in the same year, a fire was discovered in the vaulted shop of a furrier. In these shops, which are all vaults, neither fire nor candle is allowed, and the doors of them are all of iron. At length the probable cause was found to be, that the furrier, the evening before the fire, had got a roll of new cere-cloth (much in use here for covering tables, counters, &c. being easily wiped and kept clean), and had left it in his vault, where it was found almost consumed.

‡ A pood consists of 40 pounds Russ, or 36 English.

In the night between the 20th and 21st of April 1781, a fire was seen on board the frigate Maria, which lay at anchor, with several other ships, in the road off the island of Cronstadt; the fire was, however, soon extinguished; and, by the severest examination, little or nothing could be extorted concerning the manner in which it had arisen. The garrison was threatened with a scrutiny that should cost them dear; and while they were in this cruel state of suspence, an order came from the sovereign, which quieted their minds, and gave rise to some very satisfactory experiments.

It having been found, upon juridical examination, as well as private inquiry, that in the ship's cabin, when the smoke appeared, there lay a bundle of matting, containing Russian lamp-black prepared from fir-soot, moistened with hemp oil varnish, which was perceived

Inflammation. to have sparks of fire in it at the time of the extinction, the Russian admiralty gave orders to make various experiments, in order to see whether a mixture of hemp-oil varnish and the forementioned Russian black, folded up in a mat and bound together, would kindle of itself.

They shook 40 pounds of fir-wood soot into a tub, and poured about 35 pounds of hemp oil varnish upon it; thus they let stand for an hour, after which they poured off the oil. The remaining mixture they now wrapped up in a mat, and the bundle was laid close to the cabin, where the midshipmen had their birth. To avoid all suspicion of treachery, two officers sealed both the mat and the door with their own seals, and stationed a watch of four sea officers, to take notice of all that passed the whole night through; and as soon as any smoke should appear, immediately to give information to the commandant of the port.

The experiment was made the 26th of April, about 11 o'clock A. M. in presence of all the officers named in the commission. Early on the following day, about six o'clock A. M. a smoke appeared, of which the chief commandant was immediately informed by an officer: he came with all possible speed, and through a small hole in the door saw the mat smoking. Without opening the door, he dispatched a messenger to the members of the commission; but as the smoke became stronger, and fire began to appear, the chief commandant found it necessary, without waiting for the members of the commission to break the seals and open the door. No sooner was the air thus admitted, than the mat began to burn with greater force, and presently it burst into a flame.

The Russian admiralty, being now fully convinced of the self-enkindling property of this composition, transmitted their experiment to the Imperial Academy of Sciences; who appointed Mr Georgi, a very learned and able adjunct of the academy, to make farther experiments on the subject. Previous to the relation of these experiments, it is necessary to observe, that the Russian fir-black is three or four times more heavy, thick, and unctuous, than that kind of painters black which the Germans call *kien rahm*. The former is gathered at Ochta, near St Petersburgh, at Mosco, at Archangel, and other places, in little wooden huts, from resinous fir-wood, and the unctuous bark of birch, by means of an apparatus uncommonly simple, consisting of pots without bottoms set one upon the other; and is sold very cheap. The famous fine German *kien-rahm* is called in Russia *Holland's black*. In what follows, when raw oil is spoken of, it is to be understood of linseed-oil or hemp oil; but most commonly the latter. The varnish is made of five pounds of hemp-oil boiled with two ounces and a half of minium. For wrapping up the composition, Mr Georgi made use of coarse hemp-linen, and always single, never double. The impregnations and commixtures were made in a large wooden bowl, in which they stood open till they were wrapped up in linen.

Three pounds of Russian fir-black were slowly impregnated with five pounds of hemp-oil varnish; and when the mixture had stood open five hours, it was bound up in linen. By this process it became clotted; but some of the black remained dry. When the bundle had lain sixteen hours in a chest, it was observed to emit a very nauseous, and rather putrid, smell, not quite unlike that of boiling oil. Some parts of it became warm, and steamed much; this steam was watery, and by no means inflammable. Eighteen hours after the mixture was wrapped up, one place became brown, emitted smoke, and directly afterwards glowing fire appeared. The same thing happened in a second and a third place, though other places were scarcely warm. The fire crept slowly around, and gave a thick, grey, stinking smoke. Mr Georgi took the bundle out of the chest, and laid it on a stone pavement; when, on being exposed to the free air, there arose a slow burning flame, a span high, with a strong body of smoke. Not long afterwards there appeared, here and there, several chaps or clefts, as from a little volcano, the vapour issuing from which burst into flame. On his breaking the lump, it burst into a very violent flame, full three feet high, which soon grew less, and then went out. The smoking and glowing fire lasted for the space of six hours; and afterwards the remainder continued to glow without smoke for two hours longer. The grey earthy ashes, when cold, weighed five ounces and a half.

In another experiment, perfectly similar to the foregoing, as far as relates to the composition and quantities, the enkindling did not ensue till 41 hours after the impregnation: the heat kept increasing for three hours, and then the accension followed. It is worthy of remark, that these experiments succeeded better on bright days than on such as were rainy; and the accension came on more rapidly.

In another experiment, three pounds of Russian fir-black were slowly impregnated with three pounds of raw hemp-oil; and the accension ensued after nine hours.

Three quarters of a pound of German *rahm* were slowly impregnated with a pound and a half of hemp-oil varnish. The mixture remained 70 hours before it became hot and reeking: it then gradually became hotter, and emitted a strong exhalation; the effluvia were moist, and not inflammable. The reaction lasted 36 hours, during which the heat was one while stronger, and then weaker, and at length quite ceased.

Stove or chimney soot, mostly formed from birch-wood smoke, was mingled with the above-mentioned substances and tied up; the compound remained cold and quiet.

Russian fir-black, mixed with equal parts of oil of turpentine, and bound up, exhibited not the least reaction or warmth.

Birch oil, mixed with equal parts of Russian fir-black, and bound up, began to grow warm and to emit a volatile smell; but the warmth soon went off again.

From the experiments of the admiralty and of Mr Georgi, we learn, not only the decisive certainty of the self accension of soot and oil, when the two substances are mixed under certain circumstances, but also the following particulars:

Of the various kinds of soot, or lamp-black, the experiments succeeded more frequently and surely with the coarser, more unctuous, and heavier, like Russian painters black, than with fine light German rahm with coarse chimney-soot. In regard to oils, only those experiments succeeded which were made with drying oils, either raw or boiled. The proportions of the soots to the oils were, in the successful experiments, very various; the mixture kindled with a tenth, a fifth, a third, with

Inflammation.

with an equal, and likewise with a double, proportion of oil. In general, however, much more depends on the mode of mixture, and the manipulation, and, as Mr Georgi often observed, on the weather; for in moist weather the bundles, after becoming warm, would frequently grow cold again.

The instances of spontaneous inflammation hitherto mentioned have been only of vegetable substances; but we have examples of the same thing in the animal kingdom. Pieces of woollen cloth, which had not been scoured, took fire in a warehouse. The same thing happened to some heaps of woollen yarn; and some pieces of cloth took fire in the road, as they were going to the fuller. These inflammations always take place where the matters heaped up preserve a certain degree of humidity, which is necessary to excite a fermentation; the heat resulting from which, by drying the oil, leads them insensibly to a state of ignition; and the quality of the oil, being more or less deficcative, very much contributes thereto.

The woollen stuff prepared at Sevennes, which bears the name of Emperor's stuff, has kindled of itself, and burnt to a coal. It is not unusual for this to happen to woollen stuffs, when in hot summers they are laid in a heap in a room but little aired.

In June 1781, the same thing happened at a woolcomber's in a manufacturing town in Germany, where a heap of wool-combings, piled up in a close warehouse seldom aired, took fire of itself. This wool had been by little and little brought into the warehouse; and, for want of room, piled up very high, and trodden down, that more might be added to it. That this combed wool, to which, as is well known, rape-oil mixed with butter is used in the combing, burnt of itself, was sworn by several witnesses. One of them affirmed that, ten years before, a similar fire happened among the flocks of wool at a clothier's, who had put them into a cask, where they were rammed hard, for their easier conveyance. This wool burnt from within outwards, and became quite a coal; it was very certain that neither fire nor light had been used at the packing, consequently the above fires arose from similar causes. In like manner, very credible cloth-workers have certified, that, after they have bought wool that was become wet, and packed it close in their warehouse, this wool has burnt of itself; and very serious consequences might have followed, if it had not been discovered in time.

Nay, there are instances, though they be but rare, of human bodies being consumed by spontaneous inflammation. In the Philosophical Transactions, and in the Memoirs of the Academies of Paris and Copenhagen, it is related that an Italian lady (the Countess Cornelia Bandi) was entirely reduced to ashes, except her legs; that an English woman, called Grace Pitt, was almost entirely consumed by a spontaneous inflammation of her viscera: and, lastly, that a priest of Bergamo was consumed in the same manner. These spontaneous inflammations have been attributed to the abuse of spirituous liquors; but though the victims of intemperance are indeed very numerous, these certainly do not belong to that number.

The mineral kingdom also often affords instances of spontaneous inflammation. Pyrites heaped up, if wetted and exposed to the air, take fire. Pitcoal also, laid in heaps, under certain circumstances, inflames spontaneously.* M. Duhamel has described two inflammations of this nature, which happened in the magazines of Brest, in the years 1741 and 1757. Cuttings of iron, which had been left in water, and were afterwards exposed to the open air, gave sparks, and set fire to the neighbouring bodies. For this observation we are obliged to M. de Charpentier.

Inflammation || Ink.

The causes of these phenomena the chemist will assign; but they are here recorded as a warning to tradesmen and others. It is evident, from the facts which have been related, that spontaneous inflammations being very frequent, and their causes very various, too much attention and vigilance cannot be used to prevent their dreadful effects. And consequently it is impossible to be too careful in watching over public magazines and storehouses, particularly those belonging to the ordnance, or those in which are kept hemp, cordage, lampblack, pitch, tar, oiled cloths, &c. which substances ought never to be left heaped up, particularly if they have any moisture in them. In order to prevent any accident from them, it would be proper to examine them often, to take notice if any heat is to be observed in them, and, in that case, to apply a remedy immediately. These examinations should be made by day, it not being advisable to carry a light into the magazines; for when the fermentation is sufficiently advanced, the vapours which are disengaged by it are in an inflammable state, and the approach of a light might, by their means, set fire to the substances whence they proceed. Ignorance of the fore-mentioned circumstances, and a culpable negligence of those precautions which ought to be taken, have often caused more misfortunes and loss than the most contriving malice: it is therefore of great importance that these facts should be universally known, that public utility may reap from them every possible advantage.

INFORMED Stars, or Informes Stellæ, are such stars as have not been reduced into any constellation; otherwise called Sporades.—There was a great number of this kind left by the ancient astronomers; but Hevelius, and some others of the moderns, have provided for the greater part of them, by making new constellations.

Sympathetic INK is an old invention. Among the methods by which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal dust or soot.

Tuta quoque est, fallitque oculos, e lacte recenti
Litera: carbonis pulvere tange, leges.

It is obvious, that any other colourless and glutinous juice, which will hold fast the black powder strewed over it, will answer the purpose as well as milk; and therefore Pliny recommends the milky juice of certain plants to be used.

There are several metallic solutions perfectly colourless, or, at least, without any strong tint, which being wrote with, the letters will not appear until the paper be washed over with another colourless solution, or exposed to the vapour of it; but among all these there is none which excites more astonishment, or from which naturalists can draw more conclusions, than that which consists of a solution of lead in vegetable acid, and which by the vapour of arsenical liver of sulphur becomes black, even at a considerable distance. This ink, which may

may be used by conjurors, proves the subtlety of vapour, and the porosity of bodies; as the change or colouring takes place even when the writing is placed on the other side of a thin wall.

We knew before, that a solution of lead, treated in this manner, would answer the purpose of a sympathetic ink (see that article *Encycl.*); but we did not know, nor do we yet believe, that the sulphuric vapours will act upon the writing through *a wall*. Such, however, is the affirmation of Professor Beckmann, who gives an account of a still more wonderful ink from Peter Borel. This author, in a book called *Hystoriarum et observationum medico physic. centuriæ quatuor*, printed at Paris, first in 1653, and afterwards in 1657, gives a receipt for making this ink, which he calls *magnetic waters which act at a distance*. The receipt is as follows:

"Let quick lime be quenched in common water, and while quenching, let some orpiment be added to it (this, however, ought to be done by placing warm ashes under it for a whole day), and let the liquor be filtered, and preserved in a glass bottle well corked. Then boil litharge of gold, well pounded, for half an hour with vinegar, in a brass vessel, and filter the whole through paper, and preserve it also in a bottle closely corked. If you write any thing with this last water, with a clean pen, the writing will be invisible when dry: but if it be washed over with the first water it will become instantly black. In this, however, there is nothing astonishing; but this is wonderful, that though sheets of paper without number, and even a board, be placed between the invisible writing and the second liquid, it will have the same effect, and turn the writing black, penetrating the wood and paper without leaving any traces of its action; which is certainly surprising; but a fetid smell, occasioned by the mutual action of the liquids, deters many from making the experiment. I am, however of opinion, that I could improve this secret by a more refined chemical preparation, so as that it should perform its effect through a wall. This secret (says Borel) I received, in exchange for others, from J. Brosson, a learned and ingenious apothecary of Montpelier."

For making a sympathetic ink of the fifth class mentioned in the *Encyclopædia*, the following process by M. Meyer may be worthy of the reader's notice. It was entered upon in consequence of a receipt for rose-coloured sympathetic ink shewn to him by a traveller. In that receipt cobalt was the principal ingredient, and therefore the first object was to procure cobalt; but M. Meyer, being unwilling to sacrifice pure pieces of cobalt of any considerable size, made choice of one, which was visibly mixed with bismuth, iron, and quartz. He endeavoured to separate the bismuth as much as possible, and also the arsenic, if it should contain any, by bringing it slowly to a red heat; and he succeeded pretty well, as the bismuth flowed from it in abundance; and the arsenic, the quantity of which was small, was volatilised: many globules of bismuth still adhered to it. By bringing it repeatedly to a red heat, and then quenching it in water, it was reduced to such a state as to be easily pulverised. Having poured nitrous acid upon the powder, he obtained by digestion a beautiful rose red solution; the siliceous earth was separated in the form of a white slime, and by diluting it with water there was deposited a white powder, which was oxyd of bismuth. The solution being filtered, he added to it a solution of potash, and obtained a precipitate inclining more to a yellow than to a red colour. He again poured over it a little of the nitrous acid, by which a part of the oxyd was re-dissolved of a red colour: the remaining part, which had a dark brown colour, was oxyd of iron. From the solution, by the addition of potash, a precipitate was formed, which was now reddish. Having by this process obtained it pure, that he might now prepare from it the wished for red ink, he dissolved the washen pure oxyd of cobalt in different acids. That dissolved in the nitrous acid with a mixture of nitre, gave a green ink like the common: that dissolved in the sulphurous acid, without the addition of salts, gave a reddish ink, which remained after it was exposed to heat, and would not again disappear, even when a solution of nitre was applied; and that dissolved in the muriatic acid, gave a green ink, darker and more beautiful than the common. By dissolving it, however, in the acetous acid, and adding a little nitre, he obtained what he had in view; for it gave, on the application of heat, an ink of a red colour, like that of the *rosa centifolia*, which again disappeared when the paper became cold.

Inordinate, Insects.

INORDINATE Proportion, is where the order of the terms compared is disturbed or irregular. As, for example, in two ranks of numbers, three in each rank, viz. in one rank, - - - - 2, 3, 9,
and in the other rank, 8, 24, 36
which are proportional, the former to the latter, but in a different order, viz. - - 2 : 3 :: 24 : 36,
and - - 3 : 9 :: 8 : 24.
then, casting out the mean terms in each rank, it is concluded that - - - - 2 : 9 :: 8 : 36,
that is, the first is to the 3d in the first rank,
as the first is to the 3d in the 2d rank.

INSECTS (See *Encycl.*). A number of non-descript little animals was discovered by La Martiniere the naturalist when accompanying Perouse on his celebrated voyage of discovery. These animals he called *insects*, and to many of them he gave particular names. Of these we shall give his description in this place, leaving our readers, as he has left his, to arrange them properly according to the Linnæan classification.

"The insect, which is figured N° 1. inhabits a small prismatic triangular cell, pointed at the two extremities, of the consistence and colour of clear brittle ice; the body of the insect is of a green colour, spotted with small bluish points, among which are some of a golden tinge; it is fixed by a ligament to the lower part of its small habitation: its neck is terminated by a small blackish head composed of three converging scales, in the form of a hat, and enclosed between three fins, two of them large and channelled in the upper part (A) and one small, semicircular (B). When it is disturbed, it immediately withdraws its fins and its head into its cell, and gradually sinks into the water by its own specific gravity. Fig. 2. represents the under side of the prism, shewing in what manner it is channelled, in order to allow free passage to the animal when it wishes to shut itself up in it. Fig. 3. represents the profile of the same. The movement carried on by the two larger fins, which are of a softish cartilaginous substance, may be compared to that which would be produced by the two hands joined together in the state of pronation, and forming, alternately, two inclined planes and one horizontal plane: it is by means of this motion that it supports itself on the top of the water, where it probably

Plate XXX.

Infects, Inftitute.

bly feed on fat and oily fubftances on the furface of the fea." Our author found it near Nootka, on the north-weft coaft of America, during a calm.

Fig. 4. reprefents a collection of infects, as our author calls them, confifting only of oval bodies, fimilar to a foap bubble, arranged in parties of three. five, fix, and nine: among them are alfo fome folitary ones. Thefe collections of globules, being put into a glafs filled with fea water, defcribed a rapid circle round the glafs by a common movement, to which each individual contributed by fimple compreffion of the fides of its body, probably the effect of the re-action of the air with which they were filled. It is not, however, eafy to conceive how thefe diftinct animals (for they may be readily feparated without deranging their economy) are capable of concurring in a common motion. "Thefe confiderations (fays our author), together with the form of the animal, recalled to my mind, with much fatisfaction, the ingenious fyftem of M. de Buffon; and I endeavoured to perfuade myfelf, that I was about to be witnefs to one of the moft wonderful phenomena of Nature, fuppofing that thefe molecules, which were now employed in increafing or diminifhing their number, or performing their revolutions in the glafs, would foon affume the form of a new animal of which they were the living materials. My impatience led me to detach two from the moft numerous group, imagining that this number might perhaps be more favourable to the expected metamorphofis. I was, however, miftaken. Thefe I examined with more attention than the reft; and the following account is of their proceedings alone. Like two ftrong and active wreftlers, they immediately rufhed together, and attacked each other on every fide: fometimes one would dive, leaving its adverfary at the furface of the water; one would defcribe a circular movement, while the other remained at reft in the centre; their motions at length became fo rapid as no longer to allow me to diftinguifh one from the other. Having quitted them for a fhort time, on my return I found them reunited as before, and amicably moving round the edge of the glafs by their common exertions."

Fig. 5. reprefents a fingular animal, which has a confiderable refemblance to a little lizard; its body is of a firm, gelatinous confiftence; its head is furnifhed on each fide with two fmall gelatinous horns, of which the two hindermoft are fituate the furtheft inward: its body is provided with four open fan-like paws, and fome appendages near the infertion of the tail, and terminates like that of a lizard: the ridge of the back is divided the whole way down by a band of a deep blue; the reft of the body, as well as the infide of its paws, is of a bright filvery white. It appears to be very fluggifh in its motions; and when difturbed by the finger, merely turned itfelf belly upwards, foon afterwards refuming its former pofition. Fig. 6. reprefents it reverfed. Martiniere caught it during a calm at the landing place on the Bafhee Iflands.

INSTITUTE is a name which has lately been fubftituted for *fchool* or *academy*. Formerly *inftitution*, in the propriety of the Englifh language, was fometimes ufed as a word of the fame import with *inftruction*; and now *inftitute* is employed, efpecially by the admirers of French innovations, to denote what had hitherto been called an academy. When royalty was abolifhed in France, it would have been abfurd to continue the titles *Royal* Academy of Sciences, *Royal* Academy of Infcriptions, &c; but inftead of merely abolifhing the word *royal*, and fubftituting *national* in its ftead, it occurred to the fertile brain of Condorcet, to abolifh the feven academies themfelves, or rather to melt them all down into one great academy; to which was given the appellation of the

Inftitute.

National INSTITUTE, or *New Academy of Arts and Sciences*. This academy, founded on a decree of the new conftitution, was opened on the 7th of December 1795, when BENEZECH, the then minifter for the home department, attended, and the decree of foundation was read; which was to the following purport:

"The Academy of Arts and Sciences belongs to the whole republic, and Paris is its place of refidence. Its employment is to aim at bringing all arts and fciences to the utmoft perfection of which they are capable. It is to notice every new attempt, and all new difcoveries, and to keep up a correfpondence with all foreign literary focieties. And by the particular orders of the Executive Directory, its firft ftudies are to be directed to thofe fubjects which more immediately tend to the reputation and advantage of the French republic."

The academy is to confift of 288 members, half of whom are to refide in Paris, the other half in the departments; and to them is to be added a certain number of foreigners, as honorary members, confined at prefent to twenty-four.

The academy is divided into three claffes, each clafs into fections, each fection to contain twelve members.

1ft clafs. Mathematics and natural philofophy. This clafs is divided into ten fections. 1. Mathematics. 2. Mechanical arts. 3. Aftronomy. 4. Experimental philofophy. 5. Chemiftry. 6 Natural hiftory. 7. Botany. 8. Anatomy and animal hiftory. 9. Medicine and furgery. 10. Animal œconomy, and the veterinary fcience.

2d clafs. Morality and politics. This clafs confifts of fix fections. 1. Analyfis of fenfations and ideas. 2. Morals. 3. Legiflature. 4. Political œconomy. 5. Hiftory. 6. Geography.

3d clafs. Literature and the fine arts. This clafs confifts of eight fections. 1. Univerfal grammar. 2. Ancient languages. 3. Poetry. 4. Antiquities 5 Painting. 6. Sculpture. 7. Architecture. 8. Mufic.

For each clafs a particular room in the Louvre is appropriated. No one can be a member of two claffes at the fame time, but a member of one clafs may be prefent at the meetings of any other Each clafs is to print, yearly, an account of its tranfactions.

Four times a-year there are to be public meetings. On thefe occafions, the three claffes meet together. At the end of each year, they are to give a circumftantial account to the legiflative body of the progrefs made in that year in the arts and fciences. The prizes given yearly by each clafs are to be publicly notified at certain times. The fums requifite for the fupport of the inftitution are to be decreed yearly by the legiflative body, upon a requifition made by the Executive Directory.

The firft forty-eight members were chofen by the Executive Directory, to whom the choice of the remaining members was confided. To the members, refidentiary in Paris, is referved the choice both of the depart-

Institute. ment and the foreign members. On a vacancy in any clafs, three candidates are named by the clafs for the choice of the body at large.

Each clafs is to have, at its place of meeting, lection of the products, both of nature and art, and a library, according to its particular wants.

The regulations of the inftitution, with refpect to the times of meeting, and its employments, are to be drawn up by the body at large, and laid before the legiflative affembly.

The hall in which the body at large holds its meetings, forms part of the weft wing of the Old Louvre, at prefent called the Mufeum. It formerly went by the appellation of the Hall of Antiques (*Salle des Antiques*); and as long as the kings inhabited this part of the palace, was occupied by their guards, from which circumftance it obtained the name of the Hall *des Cent Suiffes*. It was likewife appropriated to banquets and entertainments, given by the court on gala days; and it was to this place that Henry IV. was conveyed, on his affaffination by Ravaillac, in the *Rue de la Ferronnerie*.

It was built at the fame time with the reft of this part of the Louvre, about the year 1528, after the defign of Pierre Lefcot, abbot of Clugny. It is 144 feet in length, and [illegible] in breadth, and holds from [illegible] to [illegible] perfons. In order to adapt it to its new deftination, the floor has been funk, which gives a greater air of lightnefs to the roof. In the centre ftands a double table, in the form of a horfe-fhoe, supported by fphinxes, at which the members of the inftitute take their feats. This table is furrounded by two tiers of benches, which are raifed for the accommodation of fpectators, who have likewife feats provided for them in the vaft embrafures of the windows, and at each extremity of the hall.

Whether fcience will be advanced by the feven royal academies having been melted into one, time muft determine; but candour compels us to acknowledge, that the proceedings of the national inftitute have hitherto been abundantly interefting. Intimately connected with the national inftitute is the French fyftem of

National Instruction, which is likewife novel, and therefore fufficiently curious to deferve notice in a Work of this kind. When the Chriftian religion was abolifhed in France, it was impoffible to continue the univerfities and other feminaries which were founded by Chriftians, and obliged by their conftitution to teach, whether pure or not, the doctrines of Chriftianity. They were accordingly all fwept away, and a new fyftem of education planned, which was to be carried on in what they call

The Primary Schools.
The Central Schools.
The School of Health.
The School of Oriental Languages.
The Polytechnic School.
The National Inftitute.
The Jury of Public Inftruction.
The Commiffion of Public Inftruction.
The Legiflative Committee of Inftruction. And various other national eftablifhments for the improvement of particular fciences. Inftitute.

The firft degree of public inftruction is to be met with in the *Ecoles Primaires*, eftablifhed by a decree of the convention of the fecond *Pluviofe*, in the fecond year of the republic (A). Every diftrict is furnifhed with one of thefe fchools; the profeffors or mafters in which are paid from the national treafury; and to which every head of a family, without exception, is compelled by law to fend its children for inftruction. The fubjects taught in thefe primary or elementary fchools are divided into nine claffes:

1ft, Inftructions connected with the phyfical and moral fituation of children, prior to their entering into thefe fchools. *2d*. Similar inftructions as a guide to teachers in the national fchools. *3d*, The arts of reading and writing. *4th*, The elements of French grammar. *5th*, Elements of arithmetic and geometry, with the theory of the new menfuration. *6th*, The elements of geography. *7th*, Explanations of the principal phenomena and productions of nature. *8th*, Elements of agriculture. *9th*, Elements of republican morals.

Next to the primary fchools in rank and confequence are the *Ecoles Centrales*, which were eftablifhed by a decree of the Convention of the feventh *Ventofe* in the third year. They are fituated in the capital of every department, bearing the proportion of one central fchool to 300,000 inhabitants. In thefe fchools the republican youths are taught the fciences, and their application in real life. In each of them are profeffors for the following branches:

1. For mathematics. 2. Experimental philofophy and chemiftry. 3. Natural hiftory. 4. Agriculture and commerce. 5. Logic and metaphyfics. 6. Political economy and legiflation. 7. The philofophical hiftory of nations. 8. The art of healing. 9. Arts and manufactures. 10. Univerfal grammar. 11. The belles lettres. 12. The ancient languages. 13. The modern languages. 14. The fine arts.

Each central fchool is furnifhed with an extenfive public library—a botanic garden—a cabinet of natural hiftory—an apparatus for experimental philofophy—and a collection of machines and models connected with the arts and manufactures.

The profeffors of each fchool hold, every month, a public fitting, in which conferences are held relative to fubjects connected with the improvement of letters, the fciences, and the arts, which are the moft beneficial to fociety.

The object in the eftablifhment of the primary and central fchools was, the general inftruction of all claffes of the citizens; and it being incompatible with the perfect completion of that important purpofe, to expect from them the propagation of particular branches of fcience, it became neceffary to eftablifh other literary and fcientific academies.

Accordingly, the French government have founded, *1ft*, Schools of health (*les ecoles de fanté*), in Paris, Strafburgh, and

(A) We would tranflate this chronological jargon into the language of Chriftian Europe, were we not perfuaded that the French calendar, the French conftitution, and the French inftitutes, will have the fame duration: we truft in God not a long duration. For *Pluviofe*, and the other fantaftical names of months introduced into this article, fee Revolution, *Encycl.* n° 184.

Institute. and Montpelier, where medicine and surgery are studied; which schools are affirmed, by those who find nothing wrong in France, to be the most perfect of their kind, as well as new and unparalleled models for such institutions.

2*d*, Two schools for Oriental languages, in the national library, and in the college of France.

3*d*, The Polytechnic school in Paris, or central school for the direction of public works. This establishment is very generally admired and considered as a model for imitation. It contains more than 400 young persons, previously educated in the mathematics, and the majority of them intended for engineers in various lines; and they labour under the immediate direction of their tutors nine hours every day. It occupies the principal part of the *Palais de Bourbon* in Paris, and is furnished with a large collection of instruments and models. The journal of the Polytechnic school, which is published by the booksellers Regent and Bertrard at Paris, is a perfectly original work, and admirably calculated to convey useful information.

Of the national institute a sufficient account has been given in the preceding article. We proceed therefore to the jury of public instruction (*Le Jury Central d'Instruction*), of which the principal business is to superintend the primary and central schools. It appoints the professors in these schools, and examines into their conduct. Like the legislative body it is renewed by a third every half year. When they have chosen a professor for a central school, they submit their choice to the department; and, in case of disapprobation, they make another appointment. To this jury of public instruction the professors in the central schools are amenable for all misconduct connected with their offices; it may expel them, but all its decisions must be submitted for confirmation to the tribunal of the department.

There is also established at Paris a supreme council, called The Commission of Public Instruction, to which is entrusted the whole executive department. The preservation of the national monuments, of public libraries, museums, cabinets, and valuable collections; the superintendance of all the schools and the modes of instruction; all new inventions and scientific discoveries; the regulation of weights and measures; national statistics and political economy, are all placed under the authority of this supreme commission. For the commodious and regular execution of so many complicated branches of business, there is a large office, called *Le Secretariat*, which is divided into three departments.

1 For the regulation of the different kinds of instruction; of the modes of education in the schools; and for the choice of elementary books. 2. For weights and measures; inventions and discoveries; libraries and bibliography; museums, works of art, and literary rewards and encouragements. 3. For theatres, national feasts, republican institutions, and the erection of monuments.

As all public establishments require the superintendance and occasional correction of the legislature, in addition to that of their own immediate executive authority, it has been deemed necessary to appoint a permanent committee of instruction in the legislative body, to provide such sums as may be necessary for the preservation and improvement of this system of instruction. This legislative committee are invested with due authority for these purposes. Their objects are precisely the same as those of the commission of public instruction above described, only with this difference, that the latter superintends the execution of existing laws, whilst the former receives and improves them, or proposes new ones. This committee is divided into three departments, as is the commission, with exactly the same arrangement of their respective labours. The committee being charged with the erection of all new laws, its members, with a view to obtain accurately all the requisite information relative to the numerous branches of the arts, have procured from the legislative body the appointment of a *commission temporaire des arts* to be annexed to them, and to meet in the same house with them; which temporary commission is divided into sixteen classes: viz. 1. For Zoology; 2. Botany; 3. Mineralogy; 4. Physics; 5. Chemistry; 6. Anatomy; 7. Machinery; 8. Geography; 9. Artillery and Fortification; 10. Medals and Antiquities; 11. Bibliography; 12. Painting; 13. Architecture; 14. Sculpture; 15. Bridges and Causeways; and, 16. Musical Instruments.

The improvements of the national literary and scientific establishments are numerous and important.

1*st*, By a decree of the convention of the 11th *Prairial*, in the second year, it was enacted, that means should be adopted by which every possible advantage might be derived from the botanic gardens of the republic, in Turkey and other foreign countries. This politic decree clearly tended to render France, in the language of the reporter, *L'abregé de tous les climats, et l'entrepôt de l'Europe*. "The epitome of every climate, and the magazine of Europe." Those plants which thrive between the tropics may be cultivated in the south of France; and those which are the produce of northern climates, may be cultivated in the northern departments; by which means, France will be in possession of all foreign plants and drugs, without the exportation of specie.

2*d*, The National Bibliography was decreed in the sitting of 22d *Germinal*, in the second year. It consists of a complete catalogue of books of all descriptions, the property of the nation; it was then ascertained, that the republic possessed more than ten millions of books. The titles of them were to be adjusted by actual comparisons; the manuscripts to be registered separately; anonymous productions were to be arranged according to their subjects; and those of known authors in the alphabetical order of the names. The several editions to be classed according to their dates: and what may be deemed more important, this French National Bibliography will contain a dictionary of anonymous books, as well as those published under fictitious names, a desideratum in the republic of letters.

3*d*, The annihilation of all *patois*, or dialects, decreed in the sitting of the 16th *Prairial*, in the second year. Notwithstanding the universality of the French language, and that it was exclusively spoken in the majority of the inland departments, yet there existed thirty various dialects in France. It is more astonishing that Rozier had remarked, that between one neighbouring village and another, there was so considerable a difference in the dialect, that the inhabitants could not understand each other; and the vinestock had thirty different names. The naturalist, Villars, has stated, that in the nomenclature of vegetables, in the departments, he had only met with an hundred which had a common appellation.

4th. The establishment of the *Conservatoire des Arts et Metiers*, was decreed in the sitting of the 8th of *Vendemiaire*, in the third year. This consists of a spacious hall, in the form of an amphitheatre, and contains the instruments and the models of machinery connected with the arts, and a description of their uses, with every book relating to them. Annexed to this establishment are three expositors and a draughtsman, who explain to the students the use of each instrument, and who register every new discovery, which is presented to the *Bureau de Consultation*, to the lyceum of arts, the *ci-devant* academy of sciences, or to the board of commerce.

5th, The establishment of the board of longitude was decreed in the sitting of the 7th of *Messidor*, third year. It was certainly a disgrace under the monarchy, that an astronomical and nautical establishment, which had already proved so beneficial to Great Britain, should not have been adopted in France. In consequence of this decree, the French board is now as complete as the English. It consists of ten members, and has under its jurisdiction the national observatory at Paris, and all the astronomical instruments belonging to the republic. It corresponds with foreign astronomers; delivers public lectures on astronomy and navigation; and its proceedings are annually recited in a public sitting.

6th, The general school of the Oriental languages was established by a decree of the 10th of *Germinal*, in the fourth year. This school adjoins to the national library, and all the books and manuscripts relative to Oriental literature are deposited in it.

7th, The national museum of antiquities was decreed in the sitting of 20th of *Prairial*, fourth year. A school of this description was successfully established at Vienna, by Eckel; at Gottingen, by Heyne; at Leipsick, by Ernest; and even at Strasburgh, by the celebrated Oberlin: Paris was, however, without one. This national archeology, or science of antiquity, is divided into nine different classes: inscriptions, characters, statues, *bas reliefs*, sculptures, paintings, mosaics, medals, civil, religious, and military instruments. This extensive establishment is under the direction of two principal professors; *le Conservateur Professeur, et le Conservateur Bibliothécaire*. The province of the former is to deliver public lectures on the several branches of antiquities, to teach the theory of medals and engravings, the history of the arts among the ancients, &c. The duties of the latter are merely of a bibliographical nature.

8th, The new modelling of the Grand National Library, was decreed in the sitting of 25th *Vendemiaire*, in the fourth year. By virtue of this decree, the place of librarian in chief was suppressed, and the whole establishment placed under a *conservatoire* of eight members; of whom two were appointed for the superintendence of printed books; two for manuscripts; two for antiquities; and two for engravings. From these a temporary director is annually chosen, who superintends the whole acts occasionally as president of this assembly, and maintains a regular correspondence with the constituted authorities relative to the concerns of the library.

9th, The augmentation of the Museum of Natural History, formerly called *Le Jardin Royal des Plantes*. This establishment was decreed the 15th *Brumaire*, third year, upon a report of Thibadeau, in the name of the committee of Public Instruction. Besides the addition of [illegible] and various other buildings, there are new collections of natural curiosities and productions; and the library is much increased. It is open to the public three times a week. At stated periods all the naturalists in Paris deliver courses of lectures in the various branches of natural history. The museum is said to have received greater improvements from this augmentation than from all the labours of Buffon, or from its foundation, since the time of Tournefort. Institute.

10th, The *Ecole des Mines* was established in the *Hotel des Monnaies*, and has for its direction the naturalist Le Sage. This institution is unrivalled in Europe; and the collection of mineralogical curiosities surpasses whatever can be conceived.

11th, The society of natural history in Paris, deservedly classes among those which have rendered the greatest services to the cause of science since the revolution. A lecture of public instruction is held every ten days, which is generally given by one of the members, and which is open to all the lovers of natural history. Premiums are proposed for dissertations; one of which, by the late C. Herman, jun. (whose early decease was a great loss to the republic of letters) on the *apterous* class of insects, may be said to constitute an epocha in the annals of natural history. The society has published a volume of memoirs, in folio, entitled, "*Transactions of the Society of Natural History.*" It has likewise erected a statue to the great Linnæus, in the national garden of plants; and, at the period when every public instruction was suspended, gave lectures on the different branches of science belonging to its department. Several intelligent and skilful navigators, among others those sent in search of the unfortunate La Peroufe, as well as those which accompanied Buonaparte on his romantic expedition to Egypt, were members of this society.

This statement of facts relative to the present state of public instruction, the sciences, the arts, and the progress of national literature in France, has been taken from a miscellany, of which the principal writers are well acquainted with what is doing in that distracted country. They call it a sublime system; and seem to consider the increase of the national library, the improvement of the botanic gardens, and the discoveries that have been made by the different schools or institutes, as furnishing a demonstration that the republican government is more favourable to the advancement of science, than the monarchical, whether absolute or limited. But it should not be forgotten, that this system is yet in its infancy; and that in prosecuting new schemes, all men, and more especially Frenchmen, are actuated by an enthusiasm which gradually cools as their pursuits become familiar. We shall therefore venture to predict, that the different schools will not display such ardour seven years hence as they do at present; and that if the republican government continue a dozen of years in France, the progress of science in that country will not be more rapid than it was under the monarchy. We must remember, too, that the French libraries, museums, and picture galleries, have been improved by means which the morals of other governments do not employ—by rapine and robbery.

That something may be learned from this system to

 improve

Inſtitute, Inſurance. improve the modes of education in other countries, we admit; and it is for that reaſon that we have inſerted an account of it. But if it contains ſomething worthy of imitation, it contains likewiſe much to be ſhunned. We do not think it conſiſtent with the *rights of man* to *compel* parents to ſend their children to be educated in *particular* ſchools; eſpecially in ſchools where not only religious inſtruction is omitted, but where, there is reaſon to believe, that the profeſſors are at pains to raze all religious impreſſions from the youthful mind. In a nation denying the truth of Chriſtianity, it is not to be ſuppoſed that the Chriſtian religion will be publicly taught; but in a nation of philoſophers, as the French call themſelves, it might have been expected that the laws of religious toleration would have been ſo far regarded, that Chriſtian parents would not have been *compelled* to ſend their children to *antichriſtian* ſchools! But it is not Chriſtianity alone that is neglected in this *ſublime* ſyſtem of education. Though the legiſlative body has ſome time ago decreed that there is a God, there is not in any one of thoſe ſchools the ſmalleſt care taken to inſtruct the republican youth in the principles even of natural religion! We might indeed have looked for it under the title *Metaphyſics*, had not the conſtitution of the National Inſtitute taught us, that French metaphyſics attend to nothing but the analyſis of ſenſations and ideas. Yet the legiſlators might have liſtened on this ſubject to a republican as ſound as themſelves, and who was likewiſe no friend to ſuperſtition. "Nam et Majorum inſtituta tueri ſacris, ceremoniiſque retinendis ſapientis eſt. Non ſolum ad religionem pertinet, ſed etiam ad *civitatis* ſtatum, ut ſine iis, qui ſacris publice præſunt, religioni privatæ ſatisfacere non poſſint." *Cicero de Nat. Deorum.*

INSURANCE, in law and commerce, though an excellent inſtitution, is not of high antiquity. The oldeſt laws and regulations concerning inſurance, with which the indefatigable Beckmann is acquainted, are the following:

On the 28th of January 1523, five perſons appointed for that purpoſe drew up at Florence ſome articles which are ſtill employed on the exchange at Leghorn. Theſe important regulations, together with the preſcribed form of policies, which may be conſidered as the oldeſt, have been inſerted, in Italian and German, by Magens, in his Treatiſe on Inſurance, average, and bottomry, publiſhed at Hamburgh in 1753.

There is ſtill preſerved a ſhort regulation of the 25th May 1537, by the Emperor Charles V. reſpecting bills of exchange and inſurance, in which the ſtrictly fulfilling only of an agreement of inſurance is commanded.

In the year 1556, Philip II. king of Spain, gave to the Spaniſh merchants certain regulations reſpecting inſurance, which are inſerted by Magens, with a German tranſlation, in his work before mentioned. They contain ſome forms of policies on ſhips going to the Indies.

In the year 1598, the *Kamer van aſſurantie*, chamber of inſurance, was eſtabliſhed at Amſterdam. An account of the firſt regulations of this inſurance office may be ſeen in Pontanus's Hiſtory of the city of Amſterdam, and in other works.

In the year 1600, regulations reſpecting inſurance were formed by the city of Middelburg in Zealand.

It appears that the firſt regulations reſpecting inſurances in England, which may be ſeen in *Anderſon's Hiſtory of Commerce*, were made in the year 1601. We find by them, that inſurers had before that period conducted themſelves in ſuch a manner, that the utmoſt confidence was repoſed in their honeſty, and that on this account few or no diſputes had ariſen. Inſurance.

Of the various policies for inſurance in England, a pretty accurate account will be found in the *Encyclopædia*; but there is one of them, of which our account muſt be acknowledged to be now defective. This is,

INSURANCE on lives; which is a policy that has greatly increaſed, in conſequence of its utility being more generally underſtood. Of the two offices for life-aſſurances, noticed in that article, the former, entitled the *Amicable Society*, has extended the number of its ſhares to 4000; but, as we have already obſerved, the nature of the inſtitution is too limited to become of general importance. The latter, entitled, the *Society for Equitable Aſſurances on Lives and Survivorſhip*, is undoubtedly one of the moſt important inſtitutions of the kind, as will appear by the following account, with which we have been favoured by an obliging correſpondent, and upon the accuracy of which our readers may depend:

The members of the equitable ſociety, finding, in June 1777, that their affairs were in a flouriſhing ſituation, reſolved to reduce their annual premiums one tenth; and in 1782, adopted new tables agreeable to the probabilities of life at Northampton, in lieu of thoſe they had hitherto uſed, formed from the London bills of mortality. But though it was evident, that the new tables were much better adapted for aſſuring promiſcuouſly perſons reſiding in the country, or in large towns, it was thought proper, for greater ſecurity, to make an addition of 15 per cent. to the real value of the aſſurances, as computed from the table of mortality at Northampton; and with the view of making an adequate compenſation to the aſſured for their former payments, which had been ſo much higher than would be required by the new rates, an addition was made to their claims of L.1 : 10s. per cent. for every premium they had paid. The conſequence of theſe meaſures proved highly favourable to the ſociety; for its buſineſs increaſed ſo faſt, that in 1785 it was nearly doubled; the ſums aſſured amounting to upwards of L.720,000. At this period, the favourable reſult of a minute and very laborious inveſtigation of the ſtate of the ſociety, induced them to take off the 15 per cent. charged upon the premiums in 1782, and make a further addition to the claims of L.1 per cent. for every payment made prior to the 1ſt January 1780. A ſtill greater increaſe of ſucceſsful buſineſs determined them, in 1791, to make another addition of L.1 per cent. to the claims; and in the following year, a further addition of L.2 per cent.; by which the claims upon aſſurances of the year 1770 were more than doubled; and thoſe of an earlier date increaſed in a ſtill higher proportion. By theſe advantages to its members, and the honourable and truly equitable manner in which the concerns of the ſociety are tranſacted, the augmentation of their buſineſs has been ſo great, that on the 31ſt December 1792, the ſums aſſured (without including the additions made to them) amounted to upwards of L.3,000,000; and on the 31ſt December 1795, to about L.4,000,000.

The

Insurance. The rates of assurance, as reduced to their real values in 1786, and according to which the society now transact business, are as follows:

Sum Assured £. 100.

Age.	*One Year.*			*Seven Years.*			*Whole Life.*		
15	£. 0	17	11	£. 1	2	11	£. 1	18	7
20	1	7	3	1	9	5	2	3	7
25	1	10	7	1	12	1	2	8	1
30	1	13	3	1	14	11	2	13	4
35	1	16	4	1	18	10	2	19	10
40	2	0	8	2	4	1	3	7	11
45	2	6	8	2	10	10	3	17	11
50	2	15	1	3	0	8	4	10	10
55	3	5	0	3	12	0	5	6	4
60	3	18	1	4	7	1	6	7	4
65	4	15	2	5	10	10	7	16	9

The other offices in London for the assurance of lives are, the *Royal Exchange Assurance*, the *Westminster Society*, and the *Pelican Life Office*

The corporation of the *Royal Exchange Assurance* was empowered to assure lives by its second charter, dated 29th April 1721; but the original object of the company being sea assurances, and the true principles of assuring on lives being at that time little understood, this branch of their business was at first comparatively small: they generally required a premium of five or six guineas per cent. without any regard to the age; and the assurance, which was usually for a small sum, was seldom for a greater term than one year. In this manner they continued to assure upon lives till the end of the year 1783, when the increasing importance of this part of their business, which they had some years felt, induced them to adopt a regular table of rates of assurance, according to the Northampton registers of mortality, but with a greater addition to the real values than had been made by the "Society for Equitable Assurances on Lives and Survivorship." This was thought proper, from the consideration that the assurers with the Royal Exchange company are not in any case liable to a call upon them beyond the premium they engage to pay, and have the security of the capital and funds of the company arising from the other branches of their business; however, the company, finding themselves successful in their life assurances, determined, in 1790, to reduce their premiums; and in 1797 made a still greater reduction, by which they are brought very near to those above stated. This company have agents in all the principal towns of Great Britain, and are impowered to assure lives in all parts of the world.

The *Westminster Society* was established in 1792, for assuring lives, and granting annuities. Their terms are nearly the same as those of the Royal Exchange Assurance; but not being a corporate body, every person assuring signs a declaration, that he accepts the joint stock of the society as his security.

The *Pelican Life Office* was instituted in 1797, by some of the principal proprietors of the Phœnix Fire Office. The rates which they have published vary considerably from those of the other offices; but whether they are founded on more just principles, time and experience must determine. This society also makes a new species of assurance, by way of endowment for daughters, or for children generally, when they shall attain the age of twenty-one years.

Integral, Interest. INTEGRAL CALCULUS, in the new analysis, is the reverse of the differential calculus, and is the finding of the integral from a given differential; being similar to the inverse method of fluxions, or the finding the fluent to a given fluxion. See FLUXIONS, *Encycl.*

INTEREST, is the allowance given for the use of money by the borrower to the lender, and is either *simple* or *compound*. The method of computing both interests is explained in the article ALGEBRA, (*Encycl.*) page 427, &c.; and the subject of simple interest is again resumed in ARITHMETIC, (*Encycl.*) n° 20. The application of the canons for the computation of compound interest, to the value of annuities, the only case in which that interest is allowed by the laws of this country, may be seen in the articles ANNUITY and SURVIVORSHIP, (*Encycl.*); where various tables are given to facilitate the different computations. Some of our readers, however, have expressed a wish to have the rule for computing compound interest so stated, as to be understood by those who are unacquainted with algebraic symbols. Their wish may be easily gratified.

The general formula $S = pR^t$ answers for the amount of any sum, whether the interest be payable yearly, half-yearly, quarterly, or daily. Let R denote the amount of one pound for the first payment, and t the number of payments, the unit being from the commencement till the first payment is due; also, let l denote the logarithm of any quantity before which it is wrote; then, from the known property of logarithms, the theorem may be expressed thus, $l.\,S = l.\,p + l.\,R \times t$.

Required the amount of L. 250 at 5 per cent. compound interest, for 12 years, reckoning the interest payable yearly, half-yearly, quarterly, and daily?

Yearly, $p = 250$, $R = 1{\cdot}05$, $t = 12$.

$$0{\cdot}0211893 = l.\,R$$
$$12$$

$$\cdot 2542716 = l.\,R \times t.$$
$$2{\cdot}3979400 = l.\,p.$$

$$l.\,S = 2{\cdot}6522116 \text{ — L. } 448:19:3\tfrac{1}{4} = \text{Amount.}$$
$$250$$

$$198:19:3\tfrac{1}{4} = \text{Comp. interest.}$$

Half yearly, $p = 250$, $R = 1{\cdot}025$, $t = 24$.

$$0{\cdot}0107239 = l.\,R.$$
$$24$$

$$428956$$
$$214478$$

$$\cdot 2573736 = l.\,R \times t.$$
$$2{\cdot}3979400 = l.\,p.$$

$$l.\,S = 2{\cdot}6553136 \text{ — L. } 452:3:7\tfrac{1}{4} = \text{Amount.}$$
$$250$$

$$202:3:7\tfrac{1}{4} = \text{Interest.}$$

Quarterly.

Quarterly. $p = 250$, $R = 1\cdot0125$, $t::48$.

$$0\cdot0053950 = l.\ R.$$
$$48$$
$$431600$$
$$215800$$
$$\cdot2589600 = l.\ R \times t.$$
$$2\cdot3979400 = l.\ p.$$

$$l.\ S = 2\cdot6569000 — L.453:16:8\tfrac{1}{2} = \text{Amount.}$$
$$250$$
$$203:16:8\tfrac{1}{2} = \text{Intereft.}$$

Daily, $p = 250$, $R = 1 + \frac{\cdot05}{365} = \frac{365\cdot05}{365}$, $t = 365 \times 12$.

$$2\cdot5623524$$
$$2\cdot5622929$$
$$\cdot0000595 = l.\ R.$$
$$4380$$
$$47600$$
$$1785$$
$$2380$$
$$\cdot2606100 = l.\ R \times t.$$
$$2\cdot3979400 = l.\ p.$$

$$l.\ S = 2\cdot6585500 — L.455:11:3\tfrac{1}{2} = \text{Amount.}$$
$$250$$
$$205:11:3\tfrac{1}{2} = \text{Intereft.}$$

INTERPOLATION, in the modern algebra, is ufed for finding an intermediate term of a feries, its place in the feries being given. See ALGEBRA and SERIES, *Encycl.*

The method of interpolation was firft invented by Mr Briggs, and applied by him to the calculation of logarithms, &c. in his Arithmetica Logarithmica, and his Trigonometria Britannica; where he explains, and fully applies, the method of interpolation by differences. His principles were followed by Reginal and Mouton in France, and by Cotes and others in England. Wallis made ufe of the method of interpolation in various parts of his works; as his arithmetic of infinites, and his algebra, for quadratures, &c. The fame was alfo happily applied by Newton in various ways: by it he inveftigated his binomial theorem, and quadratures of the circle, ellipfe, and hyperbola. See Wallis's Algebra, chap. 85. &c. Newton alfo, in lemma 5. lib. 3. Princip. gave a moft elegant folution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the fubfequent propofition, applied the folution of this problem to that of finding, from certain obferved places of a comet, its place at any given intermediate time. And Dr Waring, who adds. that a folution ftill more elegant, on fome accounts, has been fince difcovered by Meff. Nichol and Stirling, has alfo refolved the fame problem, and rendered it more general, without having recourfe to finding the fucceffive differences. *Philof. Tranf.* vol. 69. part 1. art. 7.

INTERSCENDENT, in algebra, is applied to quantities, when the exponents of their powers are radical quantities. Thus $x^{\sqrt{2}}$, $x^{\sqrt{a}}$ &c. are interfcendent quantities.

Interfcendent || Involution.

INTERSTELLAR, a word ufed by fome authors to exprefs thofe parts of the univerfe that are without and beyond the limits of our folar fyftem.

INTRADOS, the interior and lower fide, or curve, of the arch of a bridge, &c. In contradiftinction from the extrados, or exterior curve, or line on the upper fide of the arch. See ARCH in this *Suppl.*

INVOLUTION and EVOLUTION, are terms introduced into geometry by the celebrated Mr Huyghens, to exprefs a particular manner of defcribing curvilineal fpaces which occurred to him when occupied in the improvement of his noble invention of pendulum clocks. Although he was even aftonifhed at the accuracy of their motion, and they foon fuperfeded all balance clocks, he knew that the wide vibrations were fomewhat flower than the narrow ones, and that a circle was not fufficiently incurvated at the fides to render all the vibrations ifochronous. The proper curve for this purpofe became an interefting object. By a moft accurate inveftigation of the motions of heavy bodies in curved paths, he difcovered that the cycloid was the line required. Lord Brouncker had difcovered the fame thing, as alfo Dr Wallis. But we do not imagine that Huyghens knew of this; at any rate, he has the full claim to the difcovery of the way of making a pendulum ofcillate in a cycloidal arch. It eafily occurred to him, that if the thread by which the pendulum hangs be fufpended between two curved cheeks, it would alternately lap on each of them in its vibrations, and would thus be raifed out of the circle which it defcribes when fufpended from a point. But the difficulty was to find the proper form of thofe cheeks. Mr Huyghens was a moft excellent geometer, and was poffeffed of methods unknown to others, by which he got over almoft every difficulty. In the prefent cafe there was fortunately no difficulty, the means of folution offering themfelves almoft without thought. He almoft immediately difcovered that the curve in queftion was the fame cycloid. That is, he found, that while a thread unwinds from an arch of a cycloid, beginning at the vertex, its extremity defcribes the complementary arch of an equal cycloid.

Thus he added to this curve, already fo remarkable for its geometrical properties, another no lefs curious, and infinitely exceeding all the others in importance.

The fteps by which this property was difcovered are fuch direct emanations from general principles, that they immediately excited the mind of Mr Huyghens, which delighted in geometry, to profecute this method of defcribing or transforming curve lines by evolution. It is furprifing that it had not ere this time occurred to the ancient geometers of the laft century, and particularly to Dr Barrow, who feems to have racked his fancy for almoft every kind of motion by which curve lines can be generated. Evolution of a thread from a curve is a much more obvious and conceivable genefis than that of the cycloid invented by Merfennus, or that of the conchoid by Nicomedes, or thofe of the conic fections by Vieta. But except fome vague expreffions by Ptolemy and Gaffendus, about defcribing fpirals by

Involution. by a thread unlapped from a cylinder, we do not recollect any thing of the kind among the writings of the mathematicians; and it is to Huyghens alone that we are indebted for this very beautiful and important branch of geometry. It well deserves both of these epithets. The theorems which constitute the doctrines of evolution are remarkable for their perspicuity and neatness. Nothing has so much contributed to give us clear notions of a very delicate subject of mathematical discussion, namely curvature, and the measure and variations of curvature. It had become the subject of very keen debate; and the notions entertained of it were by no means distinct. But nothing can give such a precise conception of the difference of curvature, in the different parts of a cycloid or other curve, as the beholding its description by a radius continually varying in length. This doctrine is peculiarly valuable to the speculator in the higher mechanics. The intensity of a deflecting force is estimated by the curvature which it induces on any rectilineal motion; and the variations of this intensity, which is the characteristic of the force, or what we call its nature, is inferred from the variations of this curvature. The evolution and involution of curve lines have therefore great claim to our attention. But a Work like ours can only propose to exhibit an outline of the subject; and we must refer our readers to those eminent authors who have treated it in detail. Varignon, in the Memoirs of the French Academy for 1726, has been at immense pains to present it in every form; James Bernoulli has also treated the subject in a very general and systematic manner. Some account is given of it in every treatise of fluxions. We recommend the original work of Mr Huyghens in particular; and do not hesitate to say, that it is the finest specimen (of its extent) of physico-mathematical discussion that ever has appeared. Huyghens was the most elegant of all modern geometers; and both in the geometrical and physical part of this work, *De Horologio Oscillatorio*, he has preserved the utmost rigour of demonstration, without taking one step in which Euclid or Apollonius would not have followed him.

——————— *juvat integros accedere fontes*
Atque haurire.

Such authors form the taste of the young mathematician, and help to preserve him from the almost mechanical procedure of the expert symbolical analyst, who arrives at his conclusion without knowing how he gets thither, or having any notions at all of the magnitudes of which he is treating.

There are two principal problems in this doctrine.

I. To ascertain the nature of the figure generated by the evolution of a given curve.

II. To determine the nature of the curve by whose evolution a given curve may be generated.—We shall consider each of these in order, and then take the opportunity which this subject gives of explaining a little the abstruse nature of curvature, and its measures and variations, and take notice of the opinions of mathematicians about the precise nature of the angle of contact.

Plate XXXI. The curve line ABCDEF (fig. 1.) may be considered as the edge of a crooked ruler or mould; a thread may be supposed attached to it at F, and then lapped along it from F to A. If the thread be now led away from A, keeping it always tight, it is plain that the extremity A must describe a curve line A*bcdef*, and that the detached parts of the thread will always be tangents to the curve ABCDEF. In like manner will the curve line F*d'c'b* A' be described by keeping the thread fast at A, and unlapping it from the other end of the mould

This process was called by Mr Huyghens the Evolution of the curve ADF. ADF is called the Evolute. A*df* was named by him the Curve by Evolution. It has been since more briefly termed the Evolutrix, or unlapper. It has also been called the Involute; because, by performing the process in the opposite direction *fd*A, the thread is lapped up on the mould, and the whole space ADF*fd*A is folded up like a fan. The detached parts C*c*, D*d*, or C*c'*, D*d'*, &c. of the thread, are called Radii of the Evolute; perhaps with some impropriety, because they rather resemble the momentary radii of the evolutrix. We may name them the evolved radii. The beginning A of evolution may be considered as the vertex of the curves, and the ends F and *f* may be called the terms.

There is another way in which this description of curve lines may be conceived. Instead of a thread F*f* gradually lapped up on the mould, we may conceive F*f* to be a straight edged ruler applied to the mould, and gradually rolled along it without sliding, so as to touch it in succession in all its points. It is evident, that by this process the point *f* will describe the curve *fd*A, while the point F describes the other curve F*da'*. This way of conceiving it gives a great extension to the doctrine, and homologates it with that genesis of curve lines by which cycloids of all kinds are described, and which we may distinguish by the name of Provolution. For it is plain, that the relative motions of the points A and *b* are the same, whether the ruler *b*B*b'* roll on the mould ABF, or the mould roll on the ruler: but there will be a great difference in the form of the line traced by the describing point, if we suppose the plane on which it is traced to be attached to the rolling figure. Thus, when a circle rolls on a straight line, a point in its circumference traces a cycloid on the plane attached to the straight line, while the point of the straight line which quitted the circle describes on the plane attached to the circle another line; namely, the involute of the circle. This mode of description allows us to employ a curved ruler in place of the straight one *b*B*b'*; and thus gives a vast extension to the theory. But at present we shall confine ourselves to the employment of the straight line *b*B*b'*, only keeping in mind, that there is an intimate connection between the lines of evolution and of provolution.

By the description now given of this process of evolution and involution, it is plain,

1. That the evolution is always made from the convex side of the evolute.

2. That the evolved radii B*b*, C*c*, D*d*, &c. are respectively equal to the arches BA, CA, DA, &c. of the evolute which they have quitted; and that *b*B*b'*, *c*C*c'*, *d*D*d'*, &c. are always equal to the whole arch ADF.

3. That any point B of the lapped up thread describes during its evolution a curve line B*γδεφ* parallel to *bcdef*; because these curves are always equidistant from each other.

4. That if the thread extend beyond the mould as a tangent to it, the extremity *a* will describe a parallel or equidistant

equidiſtant curve *α β γ δ ε ϕ*, lying without A *b c d e f*. From this it appears that B *γ δ ε ϕ* is the complete evolutrix of FEDCB, while *b d c e f* is the evolutrix of that arch, and the added tangent B *b*. In like manner, the lapped up thread ADF, with the added part F*ϕ*, deſcribes the evolutrix *ϕ* *δ*′ *β*′ *γ*′ *α*′ A′.

5. If from any point C of the evolute there be drawn lines C *b*, C *c*, C *d*, C *e*, &c. to the evolutrix, thoſe which are more remote from the vertex are greater than thoſe which are nearer. Draw B *b*, *c* C, *d* D, *e* E, touching the evolute. C *b* is leſs than CB + B *b*; that is (2), than C *c*. Again, DC + C *c* is equal to D *d*, which is leſs than DC + C *d*. Therefore C *c* is leſs than C *d*. Now let C *e* cut D *d* in *r*. Then *e r* + *r* DE is greater than *e* E. But *e* E is equal to *d r* + *r* DE. Therefore *e r* is greater than *d r*; and *e r* + *r* C is greater than *d r* + *r* C, which is greater than *d* C. Therefore *e* C is greater than *c* C.

6. Hence it follows, that a circle deſcribed round any point of the evolute, with a radius reaching to any point of the evolutrix, will cut the evolutrix in that point, and be wholly within it on the ſide remote from the vertex, and without it on the ſide next the vertex.

7. The evolved radius cuts every arch of the evolutrix perpendicularly, or a right line drawn through the interſection at right angles touches the evolutrix in that point. Through any point *d* draw the line *m d t* at right angles to *d* D. The part of it *m d* next to the vertex is wholly without the curve, becauſe it is without the circle deſcribed round the centre D; and this circle is without the evolutrix on that ſide of *d* which is next the vertex (6). Any point *t* on the other ſide of *d* is alſo without the curve. For let *t e* E be another evolved radius, cutting D *d* in *n*: then *n d* is leſs than *n t*, becauſe *n d t* is a right angle by conſtruction; and therefore *n t d* is acute. But becauſe E *n* + *n* D are greater than ED, E *n* + *n d* are greater than ED + D*d*, that is, than E*e*, and *n d* is greater than *ne*. Therefore, ſince it is leſs than *n t*, it follows that *n e* is much leſs than *n t*, and *t* lies without the curve. Therefore the whole line *m d t* is without the curve, except in the point *d*. It therefore touches the curve in *d*, and the radius D *d* cuts it at right angles in that point. By the ſame reaſoning, it is demonſtrated, that all the curves A *b d f*, *α β δ ϕ*, A′ *b*′ *d*′ *f*′, *α*′ *β*′ *δ*′ *ϕ*′, are cut perpendicularly by the tangents to the evolute. Alſo all theſe curves interſect the evolute at right angles in their vertexes

It follows from this propoſition, that from every point, ſuch as *s*, or *i*, or *o*, &c. in the ſpace AOF comprehended by the evolute and its extreme tangents AO, FO, two perpendiculars may be drawn to the evolutrix A *d f*; and that from any point in the ſpace within the angle A *o f* only one perpendicular can be drawn; and that no perpendicular can be drawn from any point on the other ſide of ADF. Apollonius had obſerved theſe circumſtances in the conic ſections, but had not thought of marking the boundary formed by the evolute ADF. Had he noticed this, he would certainly have diſcovered the whole theory of evolution, and its importance in ſpeculative geometry.

It alſo follows from this propoſition, that if a curve A *b c d e f* is cut by the tangents of ABCDEF at right angles in every point, it will be deſcribed by the evolution of that curve: For if the evolutrix, whoſe vertex is A, be really deſcribed, it will coincide with A *b c d* in A, and have the ſame tangent; it therefore does not deviate from it, otherwiſe their tangents would ſeparate, and would not both be at right angles with the lines touching the evolute. They muſt therefore coincide throughout.

8. The arches *b c d* and *β γ δ*, intercepted by the ſame radii B *b* and D *d*, may be called *concentric*; and the angles contained between the tangents drawn thro' their extremities are equal. Thus the angle *λ π ν* is equal to *l p o*: but although equidiſtant, parallel, and containing the ſame angle between their tangents and between their radii, they are not ſimilar. Thus, the arch *α β* has a curvature at *α* that is the ſame with that of any circle whoſe radius is equal to A *α*; but the curvature at A is incomparable with it, and unmeaſurable. The ſame may be ſaid of the curvatures at *β* and at B.

9. If a circle *u d z* be deſcribed round the centre D with the radius D *d*, it both touches and cuts the evolutrix in the point *d*, and no circle can be deſcribed touching the curve in that point, and paſſing between it and the circle *u d z*: For ſince it touches the curve in *d*, its centre muſt be ſomewhere in the line *d* D perpendicular to *m d t*. It cannot be in any point *n* more remote from *d* than D is; for it would paſs without the arch *d u*, and be more remote than *d u* from the arch *d* of the evolutrix. On the other ſide, it would indeed paſs without the arch *d z*, which lies within the arch *d e* of the evolutrix: but it would alſo paſs without the curve. For it has been already demonſtrated (7) that *n d* is greater than *n e*; and the curve would lie between it and the circle *d z*.

Thus it appears, that a circle deſcribed with the evolved radius approaches nearer to the curve, or touches it more cloſely, than any other circle; all other circles either interſect it in meaſurable angles, or are within or without the curve on both ſides of the point of contact. This circle *u d z* has therefore the ſame curvature with the curve in the point of contact and coaleſcence. It is the EQUICURVE CIRCLE, the circle of equal curvature, the OSCULATING CIRCLE (a name given it by Leibnitz). The evolved radius of the evolute is the RADIUS OF CURVATURE of the evolutrix, and the point of the evolute is the CENTRE OF CURVATURE at the point of contact with the evolutrix. The evolute is the geometrical locus of all the centres of curvature of the evolutrix.

This is the moſt important circumſtance of the whole doctrine of the involution and evolution of curve lines. It is aſſumed as a ſelf evident truth by the precipitant writers of elements. It is indeed very like truth: For the extremity of the thread is a momentary radius during the proceſs of evolution; and any minute arch of the evolute nearer the vertex muſt be conceived as more incurvated than the arch at the point of contact, becauſe deſcribed with ſhorter radii: for the ſame reaſon, all beyond the contact muſt be leſs incurvated, by reaſon of the greater radii. The curvature at the contact muſt be neither greater nor leſs than that of the circle. But we thought it better to follow the example of Huyghens, and to eſtabliſh this leading propoſition on the ſtricteſt geometrical reaſoning, acknowledging the ſingular obligation which mathematicians are under to him for giving them ſo palpable a method of fixing their notions on this ſubject When the evolute of a curve is given, we have not only a clear view of the geneſis of the

the curve, with a neat and accurate mechanical method of deſcribing it, but alſo a diſtinct comprehenſion of the whole curvature, and a connected view of its gradual variations.

We ſpeak of curvature that is greater and leſſer; and every perſon has a general knowledge or conception of the difference, and will ſay, that an ellipſis is more curved at the extremities of the tranſverſe axis than any where elſe. But before we can inſtitute a compariſon between them with a preciſion that leads to any thing, we muſt agree about a meaſure of curvature, and ſay what it is we mean by a double or a triple curvature. Now there are two ways in which we may conſider curvature, or a want of rectitude: We may call that curvature which, [illegible] en ſpace, carries us twice as far from the ſtraight line; or we may call that a double curvature by which we deviate twice as much from the ſame direction. Both of theſe meaſures have been adopted; and if we would rigidly adhere to them, there would be no room for complaint: but mathematicians have not been ſteady in this reſpect, and by mixing and confounding theſe meaſures, have frequently puzzled their readers. All agree, however, in their firſt and ſimple meaſures of curvature, and ſay, that the curvature of an arch of a circle is as the arch directly, and as the radius inverſely. This is plainly meaſuring curvature by the deflection from the firſt direction. In an arch of an inch long, there is twice as much deflection from the firſt direction when the radius of the circle is of half the length. If the radius is about $57\frac{1}{4}$th inches, an arch of one inch in length produces a final direction one degree different from the firſt. If the radius is $114\frac{1}{2}$ inches, the deviation is but half of a degree. The linear deflection from the ſtraight path is alſo one half. In the caſe of circles, therefore, both meaſures agree: but in by far the greateſt number of caſes they may differ exceedingly, and the change of direction may be greateſt when the linear deviation is leaſt. Flexure, or change of direction, is, in general, the moſt ſenſible and the moſt important character of curvature and is underſtood to be its criterion in all caſes. But our proceſſes for diſcovering its quantity are generally by firſt diſcovering the linear deviation; and, in many caſes, particularly in our philoſophical inquiries, this linear deviation is our principal object. Hence it has happened, that the mathematician has frequently ſtopped ſhort at this reſult, and has adapted his theorems chiefly to this determination. Theſe differences of object have cauſed great confuſion in the methods of conſidering curvature, and led to many diſputes about its nature, and about the angle of contact; to which diſputes there will be no end, till mathematicians have agreed in their manner of expreſſing the meaſures of curvature. At preſent we abide by the meaſure already given, and we mean to expreſs by curvature or flexure the change of direction.

This being premiſed, we obſerve, that the curvature of all theſe curves of evolution where they ſeparate from their evolutes, is incomparable with the curvature in any other place. In this point the radius has no magnitude; and therefore the curvature is ſaid to be infinitely great. On the other hand, if the evolved curve has an aſſymptote, the curvature of the evolutrix of the adjacent branch is ſaid to be infinitely ſmall. Theſe expreſſions becoming familiar, have occaſioned ſome very intricate queſtions and erroneous notions. There can be little doubt of their impropriety: For when we ſay, that the curvature at A is infinitely greater than at *a*, we do not recollect that the flexure of the whole arch A *b* is equal to that of the whole arch *a* ", and the flexure at A muſt either make a part of the whole flexure, or it muſt be ſomething diſparate.

The evolutrix A *b c d f* (fig. 2.) of the common equilateral hyperbola exhibits every poſſible magnitude of curvature in a very ſmall ſpace. At the vertex A of the hyperbola it is perpendicular to the curve; and therefore has the tranſverſe axis A *r* A′ for its tangent. The curvature of the evolutrix at A is called infinitely great. As the thread unlaps from the branch ABC, its extremity deſcribes A *b c*. It is plain, that the evolutrix muſt cut the aſſymptote *r* H at right angles in ſome point G, where the curvature will be what is called infinitely ſmall; becauſe the centre of curvature has removed to an infinite diſtance along the branch AF of the hyperbola. This evolutrix may be continued to the vertex of the hyperbola on the other ſide of the aſſymptote, by cauſing the thread to lap upon it, in the ſame way that Mr Huyghens completed his cycloidal oſcillation. Or we may form another evolutrix *α δ γ δ ρ ν δ′ β′* A″, by lengthening the thread from G to *r*, the centre of the hyperbola, and ſuppoſing that, as ſoon as the curve A *δ ρ* is completed, by unlapping the thread from the branch ABC, another thread laps upon the hyperbola A″ F″. This laſt is conſidered as a more geometrical evolution than the other: For the mathematicians, extending the doctrine of evolution beyond Mr Huyghens's reſtriction to curves which had their convexity turned one way, have agreed to conſider as one continued evolution whatever will complete the curve expreſſed by one equation. Now the ſame equation expreſſes both the curves AF and A″F″, which occupy the ſame axis AA′. The cycloid employed by Huyghens is, in like manner, but one continuous curve, deſcribed by the continued provolution of the circle along the ſtraight line, although it appears as two branches of a *repeated* curve. We ſhall meet with many inſtances of this ſeemingly compounded evolution when treating of the ſecond queſtion.

Since the arch A *b d* G contains every magnitude of curvature, it appears that every kind of curvature may be produced by evolution. We can have no conception of a flexure that is greater than what we ſee at A, or leſs than what we ſee at G; yet there are caſes which ſeem to ſhew the contrary, and are familiarly ſaid, by the greateſt mathematicians, to exhibit curvatures infinitely ſmaller ſtill. Thus, let ABC (fig. 3.) be a conical parabola, whoſe parameter is AP. Let AEF be a cubical parabola, whoſe parameter is AQ. If we make AQ to AD as the cube of AP to the cube of AQ, the two parabolas will interſect each other in the ordinate DB. For, making AP $= p$, and AQ $= q$, and calling the ordinate of the conic parabola y, that of the cubic parabola z, and the indeterminate abſciſſa AD x, we have

$$p^3 : q^3 = q : x, = q^3 : z^3, \text{ and } p : q = q : z;$$

but $q : p = q : p$; therefore, by compoſition,

$$p^2 : q^2 = q^2 : px = q^2 : y^2, \text{ and } p : q = q : y;$$

therefore $z = y$, and the parabolas interſect in B.

Now, becauſe in all parabolas the ordinates drawn at the extremity of the parameters are equal to the parameters

meters, the interſections q and p will be in a line A q p, which makes half a right angle with the axis AP. Therefore, when AQ is greater than AP, the point q is without the conical parabola, and the whole arch of the cubical parabola cut off by the ordinate DB is alſo without it; but when AQ is leſs than AP, q is within the conical parabola, as is alſo the arch q B. Therefore the remaining arch BEA is without it, and is therefore leſs incurvated at A. An endleſs number of conical parabolas of ſmaller curvature may be drawn by enlarging AP; yet there will ſtill be an arch AEB of the cubical parabola which is without it, and therefore leſs incurvated. Therefore the curvature of a cubical parabola is leſs than that of any conical parabola: It is ſaid to be infinitely leſs, becauſe an infinity of cubical parabolas of *ſmaller curvature* than AEB may be drawn by enlarging AQ.

It may be demonſtrated in the ſame manner, that a paraboloid, whoſe ordinates are in the ſubbiquadrate ratio of the abſciſſæ, has an infinitely ſmaller curvature at the vertex than the cubical parabola. And the curvature of the paraboloid of the next degree is infinitely leſs than this; and ſo on continually. Nay, Sir Iſaac Newton, who firſt took notice of this remarkable circumſtance, demonſtrates the ſame thing of an endleſs ſucceſſion of paraboloids interpoſed between any two degrees of this ſeries. *Neque novit* (ſays he) *natura limitem.*

If this be the caſe, all curves cannot be deſcribed by evolution; for we have no conception of a radius of curvature that is greater than a line without limit. The theory of curvilineal motions delivered in the article DYNAMICS muſt be imperfect, or there muſt be curve lines which bodies cannot deſcribe by any powers of nature. The theory there delivered profeſſes to teach how a body can be made to deſcribe the cubical parabola, and many other curves which have theſe infiniteſimal curvatures; and yet its demonſtrations employ the radius of curvature, and cannot proceed without it. We profeſs ourſelves obliged to an attentive reader (who has not favoured us with his name) for making this obſervation. It merits attention.

There muſt be ſome paralogiſm or miſconception in all this language of the mathematicians. It does not neceſſarily follow from the arch AEB lying without the arch AIB, that it is leſs incurvated at A; it may be more incurvated between A and B. Accordingly we ſee, that the tangent BT of the conical parabola is leſs inclined to the common tangent AV than the tangent B t of the cubical parabola is; and therefore the flexure of the whole arch AEB is greater than that of the whole arch AIB; and we ſhall ſee afterwards, that there is a part of AEB that is more incurvated than any part of AIB. There is nothing correſponding to this unmeaning and inconceivable ſucceſſion of ſerieſes of magnitudes of one kind, each of which contains an endleſs variety of individuals, and the greateſt of one ſeries infinitely leſs than the ſmalleſt of the next, &c.; there is nothing like this demonſtrated by all our arguments. In none of theſe do we ever treat of the curvature at A, but of a curvature which is *not* at A. At A we have none of the lines which are indiſpenſably neceſſary for the demonſtration. Beſides, in the very ſame manner that we can deſcribe a cubical parabola, and prove that it has an arch lying without the conical parabola, we can deſcribe a circle, and demonſtrate that it has alſo an arch lying without the parabola. Theſe infiniteſimal curvatures, therefore, are not warranted by our arguments, nor does it yet appear that there are curves which cannot be deſcribed by evolution. We are always puzzled when we ſpeak of infinites and infiniteſimals as of ſomething preciſe and determinate; whereas the very denomination precludes all determination. We take the diſtinguiſhing circumſtance of thoſe different orders for a thing clearly underſtood; for we build much on the diſtinction. We conceive the curvature of the cubical parabola as verging on that of the common parabola, and the one ſeries of curvatures as beginning where the other ends. But Newton has ſhewn, that between theſe two ſerieſes an endleſs number of ſimilar ſerieſes may be interpoſed. The very names given to the curvature at the extremities of the hyperbolic evolutrix have no conceptions annexed to them. At the vertex of the hyperbola there is no line, and at the interſection with the aſſymptote there is no curvature. Theſe unguarded expreſſions, therefore, ſhould not make us doubt whether all curves may be deſcribed by evolution. If a line be incurvated, it is not ſtraight. If ſo, two perpendiculars to it muſt diverge on one ſide, and muſt converge and meet on the other in ſome point. This point will lie between two other points, in which the two perpendiculars touch that curve by the evolution, of which the given arch of the curve may be deſcribed. Finally (which ſhould decide the queſtion), we ſhall ſee by and bye, that the cubic, and all higher orders of paraboloids, may be ſo deſcribed by evolution from curves having aſſymptotic branches of determinable forms.

Such are the general affections of lines generated by evolution. They are not, properly ſpeaking, peculiar properties; for the evolutrixes may be any curve lines whatever. They only ſerve to mark the mutual relations of the evolutes with their evolutrixes, and enable us to conſtruct the one, and to diſcover its properties by means of our knowledge of the other. We proceed to ſhew how the properties of the evolutrix may be determined by our knowledge of the evolute.

This problem will not long occupy attention, being much limited by the conditions. One of the firſt is, that the length of the thread evolved muſt be known in every poſition: Therefore the length of the evolved arch muſt, in like manner, be known; and this, not only *in toto*, but every portion of it. Now this is not univerſally, or even generally the caſe. The length of a circular, parabolic, hyperbolic, arch has not yet been determined by any finite equation, or geometrical conſtruction. Therefore their evolutrixes cannot be determined otherwiſe than by approximation, or by compariſon with other magnitudes equally undetermined. Yet it ſometimes happens, that a curve is diſcovered to evolve into another of known properties, although we have not previouſly diſcovered the length of the evolved arch. Such a diſcovery evidently brings along with it the rectification of the evolute. Of this we have an inſtance in the very evolution which gave occaſion to the whole of this doctrine; namely, that of the cycloid; which we ſhall therefore take as our firſt example.

Let ABC (fig. 5.) be a cycloid, of which AD is the axis, and AHD the generating circle, and AG a tangent to the cycloid at A, and equal to DC. Let

Involution. BKE touch the cycloid in B, and cut AG in K. It is required to find the situation of that point of the line BE which had unfolded from A?.

Draw BH parallel to the base DC of the cycloid, cutting the generating circle in H, and join HA. Describe a circle KEM equal to the generating circle AHD, touching AG in K, and cutting BK in some point E. It is known, by the properties of the cycloid, that BK is equal and parallel to HA, and that BH is equal to the arch A *b* H. Because the circles AHD and KEM are equal, and the angles HAK and AKE are equal, the chords AH and KE cut off equal arches, and are themselves equal. Because BHAK is a parallelogram, AK is equal to HB; that is, to the arch A *b* H, that is, to the arch K *m* E. But if the circle KEM had been placed on A, and had rolled from A to K, the arch disengaged would have been equal to AK, and the point which was in contact with A would now be in E, in the circumference of a cycloid AEF, equal to CBA, having the line AG, equal and parallel to DC, for its base, and GF, equal and parallel to DA, for its axis. And if the diameter KM be drawn, and EM be joined, EM touches the cycloid AEF.

Cor. The arch BA of the cycloid is equal to twice the parallel chord HA of the generating circle: For this arch is equal to the evolved line BKE; and it has been shewn, that EK is equal to KB, and BE is therefore equal to twice BK, or to twice HA. This property had indeed been demonstrated before by Sir Christopher Wren, quite independent of the doctrine of evolution; but it is given here as a legitimate result of this doctrine, and an example of the use which may be made of it. Whenever a curve can be evolved into another which is susceptible of accurate determination, the arch of the evolved curve is determined in length; for it always makes a part of the thread whose extremity describes the evolutrix, and its length is found, by taking from the whole length of the thread that part which only touches the curve at its vertex.

This genesis of the cycloid AEF, by evolution of the cycloid ABC, also gives the most palpable and satisfactory determination of the area of the cycloid. For since BE is always parallel to AH, AH will sweep over the whole surface of the semicircle AHD, while BE sweeps over the whole space CBAEF; and since BE is always double of the simultaneous AH, the space CBAEF is quadruple of the semicircle AHD. But the space described in any moment by BK is also one fourth part of that described by BE. Therefore the area GAEF is three times the semicircle AHD; and the space DHABC is double of it; and the space CBAG is equal to it.

Sir Isaac Newton has extended this remarkable property of evolving into another curve of the same kind to the whole class of epicycloids, that is, cycloids formed by a point in the circumference of a circle, while the circle rolls on the circumference of another circle, either on the convex or concave side; and he has demonstrated, that they also may all be rectified, and a space assigned which is equal to their area (See *Principia*. B. I. prop. 48. &c.). He demonstrates, that the whole arch is to four times the diameter of the generating circle as the radius of the base is to the sum or difference of those of the base and the generating circle. We recommend these propositions to the attention of the young reader who wishes to form a good taste in mathematical researches; he will there see the geometrical principles of evolution elegantly exemplified.

We may just observe, before quitting this class of curves, that many writers, even of some eminence, in their compilations of elements, give a very faulty proof of the position of the tangent of a curve described by rolling. They say, for example, that the tangent of the cycloid at E is perpendicular to KE; because the line KE is, at the moment of description, turning round K as a momentary centre. This, to be sure, greatly shortens investigation; and the inference is a truth, not only when the rolling figure is a circle rolling on a straight line, but even when any one figure rolls on another. Every point of the rolling figure really *begins* to move perpendicularly to the line joining it with the point of contact. But this genesis of the arch E *e*, by the evolution of the arch B *b*, shews that K is by no means the centre of motion, nor HK the radius of curvature. Nor is it, in the case of epicycloids, trochoids, and many curves of this kind, a very easy matter to find the momentary centre. The circle KEM is both advancing and turning round its centre, and these two motions are equal, because the circle does not slide but roll, the detached arch being always equal to the portion of the base which it quits. Therefore, drawing the tangents E *g*, M *g*, and completing the parallelogram E *f* M *g*, E *f* will represent the progressive motion of the centre, and E *g* the motion of rotation. EM, the motion compounded of these, must be perpendicular to the chord EK.

The investigation that we have given of the evolutrix of the cycloid has been somewhat peculiar, being that which offered itself to Mr Huyghens at the time when he and many other eminent mathematicians were much occupied with the singular properties of this curve. It does not serve, however, so well for exemplifying the general process. For this purpose, it is proper to avail ourselves of all that we know of the cycloid, and particularly the equality of its arch BA to the double of the parallel chord HA. This being known, nothing can be more simple than the determination of the evolutrix, either by availing ourselves of every property of the cycloid, or by adhering to the general process of referring every point to an abscissa by means of perpendicular ordinates. In the first method, knowing that BE is double of BK, and therefore KE equal to HA, and KA = BH, = H *b* A, = K *m* E, we find E to be the describing point of the circle, which has rolled from A to K. In the other method, we must draw EN perpendicular to AG; then, because the point E moves, during evolution, at right angles to BE, EK is the normal to the curve described, and NK the subnormal, and is equal to the corresponding ordinate H I of the generating circle of the cycloid ABC. This being a characteristic property of a cycloid, E is a point in the circumference of a cycloid equal to the cycloid ABC.

Or, lastly, in accommodation to cases where we are supposed to know few of the properties of the evolute, or, at least, not to attend to them, we may make use of the fluxionary equation of the evolute to obtain the fluxionary equation of the evolutrix. For this purpose, take a point *e* very near to E, and draw the evolving radius *b e*, cutting E *f* (drawn parallel to the base DC) in *o*; draw *e n* parallel to the axis of the evolute, cut-

Involution.

ting E o in v; alſo draw bbi parallel to the baſe, and B d perpendicular to it. If both curves be now referred to the ſame axis CGF, it is plain that B b, B d, and db are ultimately as the fluxions of the arch, abſciſs, and ordinate of the evolute, and that E e, ev, and v E, are ultimately as the fluxions of the arch, abſciſſa, and ordinate of the evolutrix. Alſo the two fluxionary triangles are ſimilar, the ſides of the one being perpendicular, reſpectively, to thoſe of the other. If both are referred to one axis, or to parallel axes, the fluxion of the abſciſſa of the evolute is to that of its ordinate, as the fluxion of the ordinate of the evolutrix is to that of its abſciſſa. Thus, from the fluxionary equation of the one, that of the other may be obtained. In the preſent caſe, they may be referred to AD and FG, making CG equal to the cycloidal arch CBA. Call this a; AI, x; IB, y; and AB, or EB, z. In like manner, let F t be $= u$, t E $= v$, and FE $= w$; then, becauſe $DH^2 = DA^2 - AH^2$, and DA and AH are the halves of CF and BE, we have $DH^2 = \frac{a^2 - z^2}{4}$. Alſo $DI = \frac{DH^2}{DA} = \frac{a^2 - z^2}{4 \times \frac{1}{2} a}, = \frac{a^2 - z^2}{2a}$. But DI $=$ F t. Therefore F t, or u, $= \frac{a^2 - z^2}{2a}$. Alſo $\dot{w} = \frac{\dot{u}\,\dot{z}}{\dot{y}}$, by what was ſaid above, that is, $\dot{w} = \frac{a\,\dot{u}}{\sqrt{a^2 - z^2}}, = \frac{a\,\dot{u}}{\sqrt{2au}}$. Therefore we have $\dot{w} : \dot{u}\ (= a : \sqrt{2au}) = \sqrt{\tfrac{1}{2}a} : \sqrt{u} = \sqrt{GF} : \sqrt{Ft}$, which is the analogy competent to a cycloid whoſe axis is GF $=$ DA.

It is not neceſſary to inſiſt longer on this in this place; becauſe all theſe things will come more naturally before us when we are employed in deducing the evolute from its evolutrix.

When the ordinates of a curve converge to a centre, in which caſe it is called a radiated curve, it is moſt convenient to conſider its evolutrix in the ſame way, conceiving the ordinates of both as inſiſting on the circumference of a circle deſcribed round the ſame centre. Spirals evolve into other ſpirals, and exhibit ſeveral properties which afford agreeable occupation to the curious geometer. The equiangular, logarithmic, or loxodromic ſpiral, is a very remarkable example. Like the cycloid, it evolves into another equal and ſimilar equiangular ſpiral, and is itſelf the evolutrix of a third. This is evident on the ſlighteſt inſpection. Let C rqp (fig. 6.) be an equiangular ſpiral, of which S is the centre; if a radius SC be drawn to any point C, and another radius SP be drawn at right angles to it, the intercepted tangent CP is known to be equal to the whole length of the interior revolutions of the ſpiral, though infinite in number. If the thread CP be now unlapped from the arch C rq, it is plain that the firſt motion of the point P is in a direction PT, which is perpendicular to PC, and therefore cuts the radius PS in an angle SPT, equal to the angle SCP; and, ſince this is the caſe in every poſition of the point, it is manifeſt that its path muſt be a ſpiral PQR, cutting the radii in the ſame angle as the ſpiral C rqp. James Bernoulli firſt diſcovered this remarkable property. He alſo remarked, that if a line PH be drawn from every point of the ſpiral, making an angle with the tangent equal to that made by the radius (like an angle of reflection correſponding with the incident ray SP), thoſe reflected rays would all be tangents to another ſimilar and equal ſpiral I v H; ſo that PH $=$ PS. S and H are conjugate foci of an infinitely ſlender pencil; and therefore the ſpiral I v H is the cauſtic by reflection of RQP for rays flowing from S. If another equal and ſimilar ſpiral xvy roll on I v H, its centre z will deſcribe the ſame ſpiral in another poſition ouz. All theſe things flow from the principles of evolution alone: and Mr Bernoulli traces, with great ingenuity, the connection and dependence of cauſtics, both by reflection and refraction, of cycloidal, and all curves of provolution, and their origin in evolution or involution. A variety of ſuch repetitions of this curve (and many other ſingular properties), made him call it the SPIRA MIRABILIS. He deſired that it ſhould be engraved on his tombſtone, with the inſcription EADEM MUTATA RESURGO, as expreſſive of the reſurrection of the dead. See his two excellent diſſertations in *Act.* Erudit. 1692, March and May.

Another remarkable property of this ſpiral is, that if, inſtead of the thread evolving from the ſpiral, the ſpiral evolve from the ſtraight line PC, the centre S will deſcribe the ſtraight line PS. Of this we have an example in the apparatus exhibited in courſes of experimental philoſophy, in which a double cone deſcends. by rolling along two rulers inclined in an angle to other (ſee *Graveſande's* Nat. Phil. I. § 21). It is pretty remarkable, that a rolling [illegible] ſeemingly round C, as a momentary centre, ſhould produce a motion in the ſtraight line SP; and it ſhews the inconcluſiveneſs of the reaſoning, by which many compilers of elements of geometry profeſs to demonſtrate, that the motion of the deſcribing point S is perpendicular to the momentary radius. For here, although this ſeeming momentary radius may be ſhorter than any line that can be named, the real radius of curvature is longer than any line that can be named.

But it is not merely an object of ſpeculative geometric curioſity to mark the intimate relation between the geneſis of curves by evolution and provolution; it may be applied to important purpoſes both in ſcience and in art. Mr M'Laurin has given a very inviting example of this in his account of the Newtonian philoſophy; where he exhibits the moon's path in abſolute ſpace, and from this propoſes to inveſtigate the deflecting forces, and *vice verſa*. We have examples of it in the arts, in the formation of the pallets of pendulums, the teeth of wheels, and a remarkable one in Meſſrs Watt and Boulton's ingenious contrivance for producing the rectilineal motion of a piſton rod by the combination of circular motions. M. de la Hire, of the Academy of Sciences at Paris, has been at great pains to ſhew how all motions of evolution may be converted into motions of provolution, in a memoir in 1706. But he would have done a real ſervice, if, inſtead of this ingenious whim, he had ſhewn how all motions of provolution may be traced up to the evolution which is equivalent to them. For there is no organic geneſis of a curvilineal motion ſo ſimple as the evolution of a thread from a curve. It is the primitive geneſis of a circle; and it is in evolution alone that any curvilineal motion is comparable with circular motion. A given curve line is an individual, and therefore its primitive organical geneſis muſt alſo be individual. This is ſtrictly true of evolution. A parabola

Involution. bola has but one evolute. But there are infinite motions of provolution which will describe a parabola, or any curve line whatever; therefore these are not primitive organical modes of description. That this, however, is the case, may be very easily shewn. Thus let ABCD (fig. 7.) be a parabola, or any curve; and let $abcd$ be any other curve whatever. A figure $E\,m\,l\,k\,hi$ may be found such, that while it rolls along the curve $abcd$, a point in it shall describe the parabola. The process is as follows: Let Bb, Cc, Dd, &c be a number of perpendiculars to the parabola, cutting the curve $abcd$ in so many points. The perpendiculars may be so disposed that the points a, b, c, &c. shall be equidistant. Now we can construct a triangle Eeh so, that the three sides Ee, eh, and hE, shall be respectively equal to the three lines Ee, ef, Ff. In like manner may the whole figure be constructed, having the little bases of the triangles respectively equal to the successive portions of the base Abcd, and the radii equal to the perpendiculars Bb, Cc, Dd, &c. Let this figure roll on this base c. While the little side ek moves from its present position, and applies itself to ef, the point E describes an arch Ee of a circle round the centre e, and, falling within the parabola, is somewhere between E and F. Then continuing the provolution, while the next side hi turns round f till i applies to g, the point E describes another arch eFo round f, first rising up and reaching the parabola in F, when the line hE coincides with fF, and then falling within the parabola till the point h begin to rise again from f by the turning of the rolling figure round the point g. Reversing the motion, the sides ih, he, ek, &c. apply themselves in succession to the portions gf, fe, ed, &c. of the base, and the point E describes an undulating line, consisting of arches of circles round the successive centres g, f, e, &c. These circular arches all touch the parabola in the points G, F, E, &c. and separate from it a little internally. By diminishing the portions of the base, and increasing the number of the triangular elements of the rolling figure without end, it is evident that the figure becomes ultimately curvilineal instead of polygonal, and the point E continues in the parabola, and accurately describes it. It is now a curvilineal figure, having its elementary arches equal to the portions of the base to which they apply in succession, and the radii converging to E equal to the perpendiculars intercepted between the curve ABCD and the base. It may therefore be accurately constructed.

It is clear, that practical mechanics may derive great advantage from a careful study of this subject. We now see motions executed by machinery which imitate almost every animal motion. But these have been the result of many random trials of *wipers*, *snail-pieces*, &c of various kinds, repeatedly corrected, till the desired motion is at last accomplished. But it is, as we see, a scientific problem, to construct a figure which shall certainly produce the proposed motion; nor is the process by any means difficult. But how simple, in comparison, is the production of this motion by evolution We have only to find the curve line which is touched by all the perpendiculars Bb, Cc, Dd, &c. This naturally leads us to the second problem in this doctrine, namely, to determine the evolute by our knowledge of the involute: a problem of greater difficulty and of greater importance, as it implies, and indeed teaches, the curvature of lines, its measure, and the law of its variation in all particular cases. The evolute of a curve is the geometrical expression, and exhibition to the eye, of both these affections of curve lines. Involution.

Since the evolved thread is always at right angles to the evolutrix and its tangent, and is itself always a tangent of the evolute, it follows, that all lines drawn perpendicular to the arch of any curve, touch the curve line which will generate the given curve by evolution. Were this evolved curve previously known to us, we could tell the precise point where every perpendicular would touch it; but this being unknown, we must determine the points of contact by some other method, and by this determination we ascertain so many points of the evolute. The method pursued is this: When two perpendiculars to the proposed curve are not parallel (which we know from the known position of the tangents of our curve), they must intersect each other somewhere on that side of the tangents where they contain an angle less than 180°. But when they thus interfect, one of them has already touched the evolute, and the other has not yet reached it. Thus let bs, es (fig. 1.) be the two perpendiculars: being tangents to the evolute, the point s of their intersection must be on its convex side, and the unknown points of contact B and E must be on different sides of s. These are elementary truths.

Let eE approach toward bB, and now cut it in x. The contact has shifted from E to D, and x is still between the contacts. When the shifting perpendicular comes to the position cC, the intersection is at i, between the contacts B and C. And thus we see, that as the perpendiculars to the involute gradually approach, their contacts with the evolute also approach, and their intersection is always between them. Hence it legitimately follows, that the ultimate position of the intersection (which alone is susceptible of determination by the properties of the involute) is the position of the point of contact, and therefore determines a point of the evolute. The problem is therefore reduced to the investigation of this ultimate intersection of two perpendiculars to the proposed curve, when they coalesce after gradually approaching. This will be best illustrated by an example: Therefore let ABC (fig. 8.) be a parabola, of which A is the vertex, AH the axis, and AV one-half of the parameter; let BE and CK be two perpendiculars to the curve, cutting the axis in E and K, and intersecting each other in r; draw the ordinates BD, CV, and the tangent BT, and draw BF parallel to the axis, cutting CK in F, and CN in O.

Because the perpendiculars intersect in r, we have rE : EB = EK : BF. If therefore we can discover the ratio of EK to BF, we determine the intersection r. But the ratio of EK to BF is compounded of the ratio of EK to BO, and the ratio of BO to BF. The first of these is the ratio of equality; for DE and VK are, each of them, equal to AV, or half the parameter. Take away the common part VE, and the remainders EK and DV are equal, and DV is equal to BO; therefore EK : BF = BO : BF; therefore rE : rB = FO : BF, and (by division) BE : Br = FO : OB. Now let the point C continually approach to B, and at last unite with it. The intersection r will unite with a point of contact N on the evolute. The ultimate ratio of FO to OB, or of fo : oB, is evidently that of ED to

Involution.

to DT, or ED to 2DA; therefore BE : EN = ED : 2DA, or as half the parameter to twice the abſciſſa. Thus have we determined a point of the evolute; and we may, in like manner, determine as many as we pleaſe.

But we wiſh to give a general character of this evolute, by referring it to an axis by perpendicular ordinates. It is plain that V is one point of it, becauſe the point E is always diſtant from its ordinate DB by a line equal to AV; and therefore, when B is in A, E will be in V, and r will coincide with it. Now draw VP and NQ perpendicular to AH, and NM perpendicular to VP; let EB cut PV in t: then, becauſe AV and DE are equal, AD is equal to VE, and VE is equal to one-half of DT. Moreover, becauſe BD and NQ are parallel, DE : EQ = BE : EN = DE : DT; therefore DT = EQ, and VE = $\frac{1}{2}$EQ, and therefore = $\frac{1}{3}$VQ; therefore Vt is $\frac{1}{3}$ of Mt, and $\frac{1}{4}$MV. This is a characteriſtic property of the evolute. The ſubtangent is $\frac{3}{2}$ of the abſciſſa; in like manner, as in the common parabola, it is double of the abſciſſa. We know therefore that the evolute is a paraboloid, whoſe equation is $p\,x^2 = y^3$; that is, the cube of any ordinate MN is equal to the parallelopiped whoſe baſe is the ſquare of the abſciſſa VM, and altitude a certain line VP, called the parameter. To find VP, let CR be the perpendicular to the parabola in the point where it is cut by the ordinate at V; draw the ordinate RS of the paraboloid, and RG perpendicular to AH. Then it is evident, from what has been already demonſtrated, that VK is $\frac{1}{2}$ of KG, and $\frac{1}{3}$ of VG; therefore $KG^2 = 4VK^2$, and (in the parabola) $VC^2 = 2VK^2$. Alſo, becauſe KV : VC = KG : GR, we have $GR^2 = 2KG^2 = 8VK^2$; therefore $VP \times RG^2 = 8VP \times VK^2$. But $VG^3 = 27VK^3, = 27VK \times VK^2$; therefore, becauſe in the paraboloid $VP \times VS^2, = SR^3$, or $VP \times RG^2 = VG^3$, we have $8VP \times VK^2 = 27VK \times VK^2$, and $8VP = 27VK$; or VK : VP; that is, AV : VP = 8 : 27; or VP = $\frac{27}{8}$ AV, or $\frac{27}{16}$ of the parameter of the parabola ABC. The evolute of the conical parabola is the curve called the ſemicubical parabola, and its parameter is $\frac{27}{16}$ of the conical parabola.

This inveſtigation is nearly the ſame with that given by Huyghens, which we prefer at preſent to the method generally employed, becauſe it keeps the principle of inference more cloſely in view.

Mr Huyghens has deduced a beautiful corollary from it. Since the parabola ABC is deſcribed by the evolution of the paraboloid VNR, the line RC is equal to the whole evolved arch RNV, together with the redundant tangent line AV. If therefore we take from CR a part Cx equal to the redundant AV, the remainder xR is equal to the arch RNV of the paraboloid. We may do this for every poſition of the evolved radius, and thus obtain a ſeries of points V, β, γ, δ, ϵ, of the evolutrix of the paraboloid. We have even an eaſier method for obtaining the length of any part of the arch of the paraboloid, without the previous deſcription of the parabola ABC. Suppoſe Py the arch of the paraboloid, and yz the tangent; make Pz = $\frac{8}{27}$ of the parameter, and deſcribe the arch P$u\,u$ of a circle; then draw from every tangent $y\,z$ a parallel line $x\,v$, cutting the circle in u. The length of the arch yP is equal to $y\,z + u\,v$. The celebrated author congratulates himſelf, with great juſtice, on this neat exhibition of a right line equal to the arch of a curve, without the employment of any line higher than the circle. It is the ſecond curve that has been ſo rectified, the cycloid alone having been rectified by plain geometry a very few years before by Sir Chriſtopher Wren. It is very true, and he candidly admits it, that this very curve had been rectified before by Mr William Neill, a young gentleman of Oxford, and favourite pupil of Dr Wallis; as alſo by Mr Van Heuraet, a Dutch gentleman of rank, and an eminent mathematician. But both of theſe gentlemen had done it by means of the quadrature of a curve, conſtructed from the paraboloid after the manner of Dr Barrow, *Lect. Geom.* XI. Nor was this a ſolitary diſcovery in the hands of Mr Huyghens, as the rectification of the cycloid had been in thoſe of Sir Chriſtopher Wren; for the method of inveſtigation furniſhed Mr Huyghens with a general rule, by which he could evolve every ſpecies of paraboloid and hyperboloid, two claſſes of curves which come in the way in almoſt every diſcuſſion in the higher geometry. He obſerves, that the ratio of Bf to Ee, being always compounded of the ratios of Bf to Bo, and of Bo, or Dd, to Ee; and the ultimate ratio of Bf to Bo being that of TE to TD, which is given by the nature of the paraboloid, we can always find the ratio of BE to BN, if we know that of Dd to Ee. In all curves, the ratio of Dd to Ee (taken indefinitely near), is that of the ſubtangent to the ſum of the ſubtangent and ordinate of a curve conſtructed on the ſame abſciſſa, having its ordinates equal to the ſubnormals DE, de, VK, &c. In the conic ſections the ratio is conſtant, becauſe the line ſo conſtructed is a ſtraight line; and, in the parabola, it is parallel to the axis. See farther properties of it in Barrow's *Lect. Geom.* XI.

From this inveſtigation, Mr Huyghens has deduced the following beautiful theorem:

Let a be the parameter of the paraboloid, x its abſciſſa, and y its ordinate; and let the equation be $a^m x^n = y^{m+n}$; let the radius of the evolute meet the tangent through the vertex A in Z. We ſhall always have $BN = \frac{n}{m} BE + \frac{m+n}{m} BZ$. Thus,

$$\text{If}\ \left.\begin{array}{l} a\,x = y^2 \\ a^2 x = y^3 \\ a \\ a\,x^3 = y^4 \\ a^3 x = y^4 \end{array}\right\}\ \text{then } BN = \left\{\begin{array}{l} BE + 2BZ \\ \frac{1}{2}BE + \frac{3}{2}BZ \\ 2BE + 3BZ \\ 3BE + 4BZ \\ \frac{1}{3}BE + \frac{4}{3}BZ \end{array}\right.$$

&c. &c.

This is an extremely ſimple and perſpicuous method of determining the radius of the evolute, or radius of curvature; and it, at the ſame time, gives us the rectification of many curves. It is plain that every geometrical curve may be thus examined, becauſe the ſubnormals DE, VK are determined; and therefore their differences are determined. Theſe differences are the ſame with the differences of Dd and Ee; and therefore the ratio of Dd to Ee is determined; that is, the ſubſidiary curve now mentioned can always be conſtructed.

There is a ſingular reſult from this rule, which would hardly have been noticed, if the common method for determining BN had alone been employed. The equation of the paraboloid is ſo ſimple, that the increaſe of the ordinates and diminution of curvature ſeem to keep pace together; yet we have ſeen that, in the vertex of the cubical parabola, the curvature is leſs than any circular curvature that can be named. In the legs, the curvature certainly diminiſhes as they extend farther;

there must therefore be some intermediate point where the curvature is the greatest possible. This is distinctly pointed out by Mr Huyghens's theorem. The evolute of this paraboloid (having $a^3x = y^4$) is a curve ONRNQ (fig. 9.) consisting of two branches RO, and RQ, which have a common tangent in R; the branch RQ has the axis AE for its assymptote. The thread unfolding from OR, its extremity, describes the arch EC, and then, unfolding from RQ, it describes the small arch CBA. When E is extremely near A, the thread has a position BNE, in which EN is very nearly $\frac{4}{3}$BE. At C, if CE be bisected in G, GR is $\frac{1}{3}$ of CZ. Here CR the radius of curvature is the shortest possible. The evolutes of all paraboloids consist of two such branches, if $m + n$ exceeds 2.

Such is the theory of evolution and involution as delivered by Mr Huyghens about the year 1672. It was cultivated by the geometers with success. Newton prized it highly, and gave a beautiful specimen of its application to the description, rectification, and quadrature of epicycloids, trochoids, and epicycles of all kinds. But it was eclipsed by the fluxionary geometry of Newton, which included this whole theory in one proposition, virtually the same with Mr Huyghens's, but more comprehensive in its expression, and much more simple in its application. Adopting the unquestionable principle of Mr Huyghens, that the evolved thread is the radius of a circle which has the same flexures with the curve, the point of the evolute will be obtained by finding the length of the radius of the equicurve circle. The formula for this purpose is given in the article FLUXIONS of the *Encyclopædia Britannica*; but is incorrectly stated $= \frac{\overline{a+4}|^{\frac{3}{2}}}{2\sqrt{a}}$, instead of $\frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. The theorem also from which it is deduced $\left(r = \frac{\dot z^3}{-\dot x\ddot y}\right)$ is incorrectly printed, and is given without any demonstration, thereby becoming of very little service to the reader. For which reason, it is necessary to supply the defect in this place.

Therefore let AbcdEf (fig. 10.) be a circle, of which C is the centre, and ACE a diameter; let the points b, c, d, of the circumference be referred to this diameter by the equidistant perpendicular ordinates bi, cg, dk; draw the chords bc, cd, producing dc till it meet the ordinate bi in a, produce cg to the circle in f, and join bf, df; draw bh, cm, perpendicular to the ordinates; then bh, cm, hc, md, bc, cd, are ultimately proportional to the first fluxions of the abscissa AE, the ordinate cg, and the arch Ac; also ab, the difference between dm and ch is ultimately as the second fluxion of the ordinate. The triangle abc is similar to bdf; for the angle abc is equal to the alternate angle bcf, which is equal to bdf, standing on the same segment. The angle acb is equal to bfd, standing on the segment bcd; therefore the remaining angles bac and dbf are equal; therefore $ab : bc = bd : df = \frac{1}{2} bd : \frac{1}{2} df$. Now let the ordinates bi and dk continually approach the ordinate cg, and at last unite with it; we shall then have bc ultimately equal to $\frac{1}{2} bd$, and cg ultimately equal to $\frac{1}{2} df$. Therefore, ultimately, $ab : bc = bc : cg$, and $cg = \frac{bc^2}{ab}$.

Let u, v, w, represent the variable abscissa, ordinate, and arch. We have, for the fluxionary expression of the ordinate of the equicurve circle, $= \frac{\dot w^2}{-\ddot v}$ ($\ddot v$ must have the negative sign, because, as the arch increases, $\dot v$ diminishes). In the next place, it is evident that, ultimately, $bh : bc = cg : c$C, and $c\text{C} = \frac{cg \times bc}{bh}$. If r be the radius of the equicurve circle, we have $= \dot w : r$, and $r = \frac{v\dot w}{\dot u}$. But we had $v = \frac{\dot w^2}{-\ddot v}$. Substitute this in the present equation, and we obtain $r = \frac{\dot w^3}{-\dot u\ddot v}$. Lastly, observe that $\dot w^2 = \dot u^2 + \dot v^2$, and $\dot w = \sqrt{\dot u^2 + \dot v^2} = \overline{\dot u^2 + \dot v^2}|^{\frac{1}{2}}$. Therefore $\dot w^3 = \overline{\dot u^2 + \dot v^2}|^{\frac{3}{2}}$ and we have $r = \frac{\overline{\dot u^2 + \dot v^2}|^{\frac{3}{2}}}{-\dot u\ddot v}$, as the most general fluxionary expression of the radius of a circle, in terms of the sine, cosine, and arch.

When a curve and a circle have the same curvature, it is not enough that the first fluxions of their abscissæ, ordinates, and arches, are the same. This would only indicate the position of their common tangent. They must have the same deflection from that tangent. This is always equal to half of the second fluxion of the ordinate. Therefore the circle and curve must have the same second fluxion of their ordinates. Therefore let DbcdF be any curve coinciding with, or osculated by, the circle Abcd. Let its axis be DG, parallel to the diameter AE; and let cn be its ordinate. Let Dn be $= x$, $cn = y$, and $bc = z$. We have $\dot x$, $\dot y$, $\dot z$, respectively equal to $\dot u$, $\dot v$, $\dot w$. Therefore the radius of the osculating circle is $r = \frac{\dot z^3}{-\dot x\ddot y}$ or $r = \frac{\overline{\dot x^2 + \dot y^2}|^{\frac{3}{2}}}{-\dot x\ddot y}$, for all curves whatever. (We recommend the careful perusal of the celebrated 2d corollary of the 10th proposition of the 2d book of Newton's Principia, where the first principles of this doctrine are laid down with great acuteness.)

Instead of supposing the ordinates equidistant, and consequently $\dot x$ invariable, we might have supposed the ordinates to increase by equal steps. In this case y would have had no second fluxion. The radius would then be $= \frac{\dot z^3}{\dot y\ddot x}$. Or, lastly, we might suppose (and this is very usual) the arch z to increase uniformly. In this case $r = \frac{\dot z\dot y}{\ddot x}$: For because $\dot x^2 + \dot y^2 = \dot z^2$, by taking the fluxion of it, $2\dot x\ddot x + 2\dot y\ddot y = 0$, and $\ddot y = \frac{\dot x\ddot x}{-\dot y}$; and therefore $r = \frac{\dot z^3}{\dot y\ddot x - \dot x\ddot y}, = \frac{\dot z^3}{\dot y\ddot x + \frac{\dot x^2\ddot x}{\dot y}}, = \frac{\dot z^3}{\dot y^2 + \dot x^2 \times \frac{\ddot x}{\dot y}}, = \frac{\dot y\dot z}{\ddot x}$.

Having thus obtained the radius of curvature, and consequently a point of the evolute, we determine its

form

Involution.

form by reference to an abscissa, without much farther trouble: It only requires the drawing Cp perpendicular to the axis of the proposed curve, and giving the values of Cp and Dp. If we suppose $\dot{x}$ constant, then, cC being $=\frac{\dot{z}^3}{-\dot{x}\ddot{y}}$, we have Dp ($=Dn+gc$, $=Dn+\frac{\dot{y}}{\dot{z}}\times cC$) $=x+\frac{\dot{y}\dot{z}^2}{-\dot{x}\ddot{y}}$; and pC ($=cg-cn$, $=\frac{\dot{x}}{\dot{z}}\times cC-cn$) $=\frac{\dot{z}^2}{-\ddot{y}}-y$. But if we suppose $\dot{y}$ constant; then, cC being $=\frac{\dot{z}^3}{\dot{y}\ddot{x}}$, we have $Dp=x+\frac{\dot{z}^2}{\ddot{x}}$, and $pC=\frac{\dot{x}\dot{z}^2}{\dot{y}\ddot{x}}-y$. And if $\dot{z}$ be constant, then, cC being $=\frac{\dot{y}\dot{z}}{\ddot{x}}$, we shall have $Dp=x+\frac{\dot{y}^2}{\ddot{x}}$, and $pC=\frac{\dot{x}\dot{y}}{\ddot{x}}-y$.

These formulæ are so many general expressions for determining both the curvature of the proposed curve and the form of its evolute. They also give us the rectification of the evolute; because cC is equal to the evolved arch, or to that arch, together with a constant part, which was a tangent to the evolute at its vertex, in those cases where the involute has a finite curvature at its vertex; as in the common parabola.

Let us take the example of the common parabola, that we may compare the two methods. The equation of this is $ax=y^2$, or $a^{\frac{1}{2}}x^{\frac{1}{2}}=y$. This gives $\dot{y}=\frac{1}{2}a^{\frac{1}{2}}\dot{x}x^{-\frac{1}{2}}$, $=\frac{a^{\frac{1}{2}}\dot{x}}{2x^{\frac{1}{2}}}$, and (making $\dot{x}$ constant) $\ddot{y}=-\frac{1}{2}\times\frac{1}{2}a^{\frac{1}{2}}\dot{x}^2x^{-\frac{3}{2}}=\frac{-a^{\frac{1}{2}}\dot{x}^2}{4x^{\frac{3}{2}}}$. Wherefore $\dot{z}$ ($=\sqrt{\dot{x}^2+\dot{y}^2}$) $=\frac{\dot{x}}{2}\sqrt{\frac{4x+a}{x}}$, and the radius of curvature $\left(=\frac{\dot{z}^3}{-\dot{x}\ddot{y}}\right)=\frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. At the vertex, where $x=0$, the formula becomes $=\frac{1}{2}a$. Again, $Dp\left(=x+\frac{\dot{y}\dot{z}^2}{-\dot{x}\ddot{y}}\right)$ becomes $\frac{1}{2}a+3x$; and therefore $Vp=3x$, = the abscissa of our evolute. Likewise cp, its ordinate, $\left(=\frac{\dot{z}^2}{-\ddot{y}}-y\right)=\frac{4x^{\frac{3}{2}}}{\sqrt{a}}$; and $Cp^2=\frac{16x^3}{a}$; and $Cp^2\times a=16x^3$. But $Vp=3x$, and $Vp^3=27x^3$. Therefore $Cp^2\times\frac{1}{16}$th $a=x^3$, $=\frac{1}{27}$th Vp^3, and $\frac{27}{16}$ths $a\times Cp^2=Vp^3$. Therefore the evolute VC is a semicubical parabola, whose parameter is $\frac{27}{16}a$, as was shewn by Mr Huyghens. The arch VC is $=\frac{\overline{a+4x}|^{\frac{3}{2}}}{2\sqrt{a}}-\frac{1}{2}a$.

We shall give one other example, which comprehends the whole class of paraboloids. Their general equation is $y=ax^n$. This gives us $\dot{y}=nax^{n-1}\dot{x}$, and $\ddot{y}=n\times\overline{n-1}\times ax^{n-2}\dot{x}^2$; therefore $\dot{z}$ ($=\sqrt{\dot{x}^2+\dot{y}^2}$) $=\dot{x}\sqrt{1+n^2a^2x^{2n-2}}$; $Cc\left(=\frac{\dot{z}^3}{-\dot{x}\ddot{y}}\right)=\frac{\overline{1+n^2a^2x^{2n-2}}|^{\frac{3}{2}}}{-n\times\overline{n-1}\times ax^{n-2}}$; $Dp\left(=x+\frac{\dot{y}\dot{z}^2}{-\dot{y}\ddot{x}}\right)=x-\frac{x+n^2a^2x^{2n-1}}{n-1}$; $Cp\left(=\frac{\dot{z}^2}{\ddot{y}}-y\right)=\frac{1+\overline{2n-1}\times na^2x^{2n-2}}{-\overline{n-1}\times nax^{n-2}}$; and $DV=-\frac{n^2a^2o^{2n}}{n-1}$.

This last formula expresses the radius of curvature at the vertex D, or the redundant part of the thread, by which it exceeds the arch VC of the evolute. If $n=\frac{1}{2}$, the formula becomes $\frac{a^2}{2}$: but if n be greater than this, VC will be $=o$; and if it be less, VC will be infinite. Hence it appears, that the radius of curvature at the vertex of a curve is a finite quantity only in the cases where the first or nascent ordinates are in the subduplicate ratio of their abscissæ. In all other cases, the curvature is incomparable with that of any circle, being either what is called infinite (when n is greater than $\frac{1}{2}$) or nothing (when it is less).

We scruple not to say, that the method of Mr Huyghens is more luminous, more pleasing to the imagination of a geometer, than this; and in all the cases which occurred to us in our employment of it, it suggested more ready constructions, with the additional satisfaction of exhibiting, in a continuous train, what the *symbolical* method, proceeding by the fluxionary calculus, only indicates by points. We must also observe, that the subsidiary curve employed by Huyghens, having its ordinates equal to the subnormals of the involute under examination, is the geometrical expression of that function of the involute which gives the second fluxions $\ddot{y}$ and $\ddot{x}$ of the ordinate and abscissa. The young mathematician will find no difficulty in constructing this curve *in every case*; whereas we imagine that he will not find it a light matter to construct the final equations of the symbolic method *almost in any case*. At the same time, the all-comprehending extent of the latter method, and the numberless general theorems which it suggests to the expert analyst, give it a most deserved preference, and make it almost an indispensable instrument for all who would extend our physico mathematical sciences.

In the employment of the geometry of curve lines, especially in the doctrine of centripetal forces, it is usual to consider the ordinates, not as insisting on a rectilineal abscissa, but as diverging from a centre. This is also the usual way of conceiving all spirals and evolutrixes of curves which include space; in short, all RADIAL curves. The process for finding their evolute, or their radius of curvature, is somewhat different from that hitherto exhibited; but it is more simple. Thus, let GPM (fig. 10.) be the elliptical path of a planet, of which S is the focus. We require PC, the radius of curvature in the point P. Let Pp be a very small arch. Draw the radii SP, Sp, the tangents PT, pt; and

and draw ST perpendicular to PT, cutting pt in t; and Po perpendicular to Sp. Let the arch GP be $= z$, the radius SP $= y$, and the perpendicular ST $= p$. Then, it is plain, that Pp, op, Tt, are ultimately proportional to $\dot{z}$, $\dot{y}$, $\dot{p}$. The triangles PCp, and Tpt or TPt are alſo ultimately ſimilar; as alſo the triangles PST and poP. Therefore, ultimately,

$$\text{T}t : \text{P}p = \text{PT} : \text{PC}$$

alſo

$$\text{P}p : po = \text{PS} : \text{PT}$$

therefore Tt : po = PS : PC, or, $\dot{p} : \dot{y} = y : r$, and $r = \frac{y\dot{y}}{\dot{p}}$; an expreſſion of the radius of curvature, extremely ſimple, and of eaſy application.

The logarithmic or equiangular ſpiral PQR (fig. 6.) affords an eaſy example of the uſe of this formula. The angle SPT, which the ordinate makes with the curve, is everywhere the ſame. Therefore let a be our tabular radius, and b the ſine of the angle SPT. We have

$$\text{ST} = \frac{by}{a}\text{; and therefore PC}\left(= \frac{y\dot{y}}{\dot{p}}\right) = \frac{ay\dot{y}}{b\dot{y}} = \frac{ay}{b}.$$

This is to SP or y in the conſtant ratio of a to b, or of SP to ST: that is, ST : SP = SP : PC, the triangles SPT and PCS are ſimilar, the angles at P and C equal, and C is a point of an equiangular ſpiral pyr round the centre S.

It is not meant that the conſtruction pointed out by this theory of involution, expreſſed in its moſt general and ſimple form, is always the beſt for finding the centre of the equicurve circle. Our knowledge of, or attention to, many other properties of the curve under conſideration, beſides thoſe which ſimply mark its relation to an abſciſs and ordinate, muſt frequently give us better conſtructions. But evolution is the natural geneſis of a line of varying curvature. Moreover, in the moſt important employment of mathematical knowledge, namely, mechanical philoſophy, it is well known, that the moſt certain and comprehenſive method of ſolving all intricate problems is by reference of all forces and motions to three co-ordinates perpendicular to each other. Thus, without any intentional ſearch, we have already in our hands the very fluxionary quantities employed in this doctrine; and the expreſſion which it gives of the radius of curvature requires only a change of terms to make it a mechanical theorem.

Thus have we conſidered the two chief queſtions of evolution and involution. We have done it with as cloſe attention to geometry as poſſible, that the reader's mind may become familiar with the *ipſa corpora* while acquiring the elementary knowledge, which is to be employed more expeditiouſly afterwards by the help of the ſymbolical analyſis. Without ſuch ideas in the mind, the occupation is oftentimes as much diveſted of thought as that of an expert accountant engaged in complex calculations; the attention is wholly turned to the rules of his art.

It now remains to conſider a little the nature of this curvature of which ſo much has been ſaid, and about which ſo many obſcure opinions have been entertained. We mentioned, in an early part of this article, the unwarranted uſe of the terms of infinite and infiniteſimal magnitude as applicable to curvature, and ſhewed its impropriety by the inconſiſtences into which it leads mathematicians. Nothing threw ſo much light on this ſubject as Mr Huyghens's Geometry of Evolution; and we ſhould have expected that all diſputes would have been ended by it. But this has not been the caſe; and even the moſt eminent geometers and metaphyſicians, ſuch as the Bernoullis and Leibnitz, have given explanations of orders of curvature that can have no exiſtence, and explanations of that coaleſcence which obtains between a curve line and its equicurve circle, which are not warranted by juſt principles.

Theſe errors (for ſuch we preſume to think them) aroſe from the method employed by the geometers of laſt century for obtaining a knowledge of the magnitude and variation of curvature. The ſcrupulous geometers of antiquity deſpaired of ever being able to compare a curve with a right line. The moderns, although taught by Des Cartes to define the nature of a curve by its equation, allowed that this only enabled them to exhibit a ſeries of points through which it paſſed, and to draw the polygon which connects theſe points, but gave no information concerning the continuous *incurvated* arches, of which the ſides of the polygon are the chords. They could not generally draw a tangent to any point, or from any point; but they could draw a chord through any two points. Des Cartes was the firſt who could draw a tangent. He contrived it ſo, that the equation which expreſſes the interſections of the curve with a circle deſcribed round a given centre ſhould have two equal roots. This indicates the coaleſcence of two interſections of the common chord of the circle and the curve. Therefore a perpendicular to the radius ſo determined muſt touch the curve in the point of their union. This was undoubtedly a great diſcovery, and worthy of his genius. It naturally led the way to a much greater diſcovery. A circle may cut a curve in more points than two: It may cut a conic ſection in four points, all expreſſed by one equation, having four roots or ſolutions. What if three of theſe roots ſhould be equal? This not only indicates a cloſer union than a mere contact, but alſo gives indication of the flexure of the intervening arch. For, before the union, the interſections were in the arch both of the curve and of the circle; and therefore the diſtinction between the union of two and of three interſections muſt be of the ſame kind with that between a ſtraight line and an arch of *this* circle. The flexure of a circle being the ſame in every part, it becomes a proper index; and therefore the circle, which is determined by the coaleſcence of three interſections, was taken as the meaſure of the curvature in that point of the curve, and was called the CIRCLE OF CURVATURE, the EQUICURVE CIRCLE. There is a certain progreſs to this coaleſcence which muſt be noticed. Let ABD (fig. 4.) be a common parabola, EBF a line touching it in B, and BO a line perpendicular to EBF. Taking ſome point O in the other ſide of the axis for a centre, a circle may be deſcribed which cuts the curve in four points a, b, c, and d. By enlarging the radius, it is plain that the points a and b muſt ſeparate, as alſo the points c and d. Thus, the points b and c approach each other, and at laſt coaleſce in a point of contact B, with the parabola, and with its tangent. In the mean time, a and d have retired to A and D. If we now bring the centre O nearer to B, the new circle will fall wholly within the laſt circle ABD; and therefore both

Involution. A and D will again approach to each other, and to B, which still continues a point of contact. It is plain that A will approach faster to B than D will do. At length, the centre being in *o*, the point A coalesces with B, and we obtain a circle *ι* B *δ*, touching the curve in B, and cutting it in *δ*: Consequently the arch B *ι δ* is wholly within, and B *ν δ* is wholly without the parabola; and the circle both touches and cuts the parabola in B. Here is certainly a closer union, at least on the side of *a*. But perhaps a farther diminution of the circle may bring it closer on the side of D. Join B *δ*. Let a smaller circle be described, touching the parabola in B, and cutting it in *ν*. Draw *ν c* parallel to *δ* B. It may be demonstrated that the new circle cuts the parabola in *c*. Now the arch between *c* and *ν* being without the parabola, the arch B C must be within it; and therefore this circle is within the parabola on both sides of B, and is more incurvated than the parabola. We have seen, that a circle greater than *ι* B *δ* is without the parabola on both sides of B; and therefore is less incurvated than the parabola. Therefore the individual circle *ι* B *δ* is neither more nor less curve than the parabola in the point B. Therefore the circle indicated by the coalescence of three intersections is properly named the equicurve circle; and, since we measure all curvatures by that of a circle, it is *properly* the circle of curvature, and its radius is the radius of curvature.

Had B been the vertex of the axis, every intersection on one side of B would have been similar to an intersection on the other, and there would always have been two pairs of roots that are equal; and therefore when three intersections coalesce, a fourth also coalesces, and the contact is said to be still closer.

What has now been shewn with respect to a conic section is true of every curve. When two intersections coalesce, there is a common tangent; when three coalesce, there is an equal curvature, and no other circle can pass between this circle and the curve. There cannot be a coalescence of four intersections, except when the diameter is perpendicular to the ordinates, and those are bisected by the diameter.

Mr Leibnitz, who valued himself for metaphysical refinement, and never fails to claim superiority in this particular, notices the important distinction between a simple contact and this closer union, in a very well written dissertation, published in the *Acta Eruditorum*, July 1686. He calls the contact of equal curvatures an OSCULATION, and the circle of equal curvature the OSCULATING CIRCLE, and delivers several very judicious remarks with the tone of a master and instructor. He also speaks of different degrees or orders of osculation, each of which is infinitely closer than the other, as a thing not remarked by geometers. But Sir Isaac Newton had done all this before. The first twelve propositions of the *Principia* had been read to the Royal Society several years before, and were in the Registers. The *Principia* had received the imprimatur of the Society in July 1686; but was almost printed before that time. In the Scholium to the 11th Lemma, is contained the whole doctrine of contact and osculation; and in the lemma and its corollaries, is crowded a body of doctrine, which has afforded themes for volumes. The author glances with an eagle's eye over the whole prospect, and points out the prominent parts with the most compressed brevity; but with sufficient precision for marking out the more important objects, and particularly the different orders of curvature. This lemma and its corollaries are continually employed in the twelve propositions already mentioned. In 1671 he had written the first draught of his method of fluxions, where this doctrine is systematically treated; and Mr Collins had a copy of it ever since 1676. It is well known that Leibnitz, when in London, had the free perusal of the Society's records, and information at all times by his correspondence with the secretary Oldenburgh and Mr Collins. His conduct respecting the theorems concerning the elliptical motion of the planets, and the resistance of fluids, leave little room to doubt of his having availed himself in like manner of his opportunity of information on this subject. He gives a much better account of the Newtonian doctrine on this subject than in those other instances, it being more suited to his refining and paradoxical disposition. Involution.

In this and another dissertation, he considers more particularly the nature of evolution, and of that osculation which obtains between the evolutrix and the circle described by the evolved radius. He says, that it is equivalent to two simple contacts, each of which is equivalent to two intersections. An osculation produced in the evolution of a curve is therefore equivalent to four intersections. And he advises, with an air of authority, the mathematicians to attend to these remarks, as leading them into the recesses of science. He is mistaken, however; and the listening to him would prevent us from forming a just notion of osculation, and from conceiving with distinctness the singular fact of a circle both touching and cutting a curve in the same point. James Bernoulli lost his friendship, beca... presumed to say that the presence of four intersection... in an osculation is not warranted by the equation expressing those intersections.

Mr Leibnitz was misled by the way in which he had considered the osculation in the evolution of curves. It merits attention. From any point within the space ADFOA (fig. 1.), two perpendiculars may be drawn to the evolutrix A *b d f*; and therefore two circles may be described round that point, each touching the curve. Each contact is the union of two intersections. Therefore, as the centre approaches the evolute, the contacts approach each other, and they unite when the centre reaches the evolute. Therefore the osculation of evolution is equivalent to four intersections.

But when two such circles are described round a point *ε*, so as that both may touch the evolutrix A *a f*, the point *ε* is in the intersection of one evolved radius with the *prolongation* of another. The contact at the extremity *b* of the prolonged radius *b* B is an exterior contact, and the arch of the circle crosses the evolutrix, from without inwards, in some point more remote from A. The contact at the extremity *e* of the radius *ε* E is an interior contact; and if *ε e* be greater than the straight line EA, the arch of this circle crosses the curve, from within outwards, in some point nearer to A. Thus each contact is accompanied by an intersection on the side next the other contact, sometimes beyond it, and sometimes between the contacts. As the contacts approach, the intersections also approach, still retaining their characters as intersections, as the contacts still continue contacts. Also the circle next to A crosses from without inwards, and that next to *f* crosses from

within

[illegible] within outwards. They [illegible] in this character to the last; and when the [illegible] coalesce, the [illegible] obsolete over them [illegible] circumference, still, however, crossing the curve in the same direction as before; that is, without the curve on the side of A, and within it on the side of *f*. The contacts unite as contacts, and the intersections as intersections. Thus it is that the osculating circle both touches and intersects the curve in the same point.

At *f* the osculation is indeed closer than anywhere else. The variation of curvature is less there than anywhere else, because the radius changes more slowly. It is this circumstance that determines the closeness of contact. If a circle osculates a curve, it has the same curvature. If this curvature does not change in the vicinity of the contact, the curve and circle must coincide; and the deviation of the circle (the curvature of which is everywhere the same) from the curve must proceed entirely from the variation of its curvature. This, therefore, is the important circumstance, and is indeed the characteristic of the figure as a curve line; and its other properties, by which the position of its different parts are determined, may be ascertained by means of the *variation* of its curvature, as well as by its relation to co-ordinates. Of this we have a remarkable instance at this very time. The orbit of the newly discovered planet has been ascertained with tolerable precision by means of observations made on its motions for three years. In this time it had not described the 20th part of its orbit; yet the figure of this orbit, the position of its transverse axis, the place and time of its perihelion, were all determined within 100dth part of the truth by the *observed variation* of its curvature. It therefore merits our attention in the close of this article. We know of no author who has treated the subject in so instructive a manner as Mr M'Laurin has done, by exhibiting the theorem which constitutes Newton's 11th lemma in a form which points this out even to the eye (see *M'Laurin's Fluxions*, Chap. xi. § 363, &c.). We earnestly recommend this work to the young geometer, as containing a fund of instruction and agreeable exercise to the mathematical genius, and as greatly superior in perspicuity and in ideas which can be treasured up and recollected, when required, to the greatest part of the elaborate performances of the eminent analysts of later times. By expressing every thing geometrically, the author furnishes us with a sort of picture, which the imagination readily reviews, and which exhibits in a train what mere symbols only give us a momentary glimpse of.

"As, of all right lines which can be drawn through a given point in the arch of a curve, that alone is the tangent which touches the arch so closely that no right line can pass between them; so, of all circles which touch a curve in a given point, that circle alone has the same curvature which touches it so closely that no circle can pass between them. It cannot coincide with the arch of the curve; and therefore the above condition is sufficient for making it equicurve. As the curve separates from the tangent by its flexure or curvature, it separates from the equicurve circle by its *change* of curvature; and as its curvature is greater or less according as it separates more or less from its tangent, so the variation of its curvature is greater or less according as it separates more or less from its equicurve circle. There can be but one equicurve circle at one point of a curve, otherwise any other circle described between them through that point will pass between the curve and the equicurve circle. Involution.

"When two curves touch each other in such a manner that no circle can pass between them, they must have the same curvature; because the arch which touches one of them so closely that no circle can pass between them, must touch the other in like manner. But circles may touch the curve in this manner, and yet there may be indefinite degrees of more or less intimate contact between the curve and its equicurve circle." This is shewn by the ingenious author in a series of propositions, of which a very short abridgment must suffice in this place.

Let any curve EMH (fig. 11.), and a circle ERB, touch a right line ET on the same side at E. Let any right line TK, parallel to the chord EB of the circle, meet the tangent in T, the curve in M, and a curve BKF (which passes through B) in K. Then, if $MT \times TK$ be everywhere equal to TE^2, the curvature of EMH in the point E is the same as that of the circle ERB; and the contact of EM and ER is so much the closer the smaller the angle is which is contained at B between the curve BKF and the equicurve circle BQE.

Let TK meet the circle in R and Q. Then, because $RT \times TQ = TE^2$, it must be $RT \times TQ = MT \times TK$; and $RT : MT = TK : TQ$. The line BKF may have any form. It may cross the circle BQR in B, as in the figure. It may touch it, or touch EB, &c. Let us first consider what situations of the point M correspond with the position of K, in that part of the curve BKF which lies without the circle BRE. Let TK move toward EB, always keeping parallel to it, till it coincide with it, or even pass it. Then, while the point K describes KB, it is evident that since TK is greater than TQ, TM must be less than TR, and the point M must always be found between T and R. The arch ME of the curve must be nearer to the tangent than the arch RE of the circle. If any circle be now described touching TE in E, and cutting off from EB a smaller chord than EB, it is clear that the whole of this segment must be within the segment BRE; therefore this smaller circle does not pass between ERB and the curve EMH. But since we see that the curve lies without the circle, in the vicinity of E, perhaps a greater circle than ERB may pass between it and the curve. A greater circle, touching at E, must cut off a chord greater than EB. Let E*rb* be such a circle, cutting EB in *b*, and TQ in *q*. T*q* is necessarily greater than TQ. For since *b* is beyond B, and the arch BKF lies in the angle QB*b*, the circle E*rq* must cross the curve FKB in some point; suppose F. Then while K is found in the arch FB, the point *q* must be beyond K, or T*q* must be greater than TK. Now $Tr \times Tq = TE^2, = TM \times TQ$. Therefore $TM : Tr = Tq : TQ$. Therefore T*q* being greater than TQ, T*r* must be less than TM, and the point *r* must lie without the curve, and the arch E*r* does not pass between EMH and the circle ERB. In like manner, on the other side of EB, it will appear, that when the curve BK'F falls within the circle which touches EMH in E, and cuts off the chord EB, the arch of the curve corresponding to the arch BK'F, lying within the circle, also lies within the circle. For TK' being less than TQ', TM' is greater than TR', and the curve is within

Involution within the circle. And, by similar reasoning, it is evident that a circle cutting off a greater chord falls without both the circle ERB and the curve, and that a circle less than ERB must necessarily have some part of the curve BKF without it; and therefore TK′ will be greater than Tq', and the corresponding point r' must be without the curve. All circles therefore touching TE in E fall without both ER and EM, or within them both, according as they cut off from EB a chord greater or less than EB, and no circle can pass between them when the rectangle MT × TK is always equal to ET², and the focus of the point K passes through B; that is, ERB is the equicurve circle at E.

This corroborates the several remarks that we have made on the circumstance of a circle touching and cutting a curve in the same point. No other circle can be made to pass between it and the curve, and it therefore has the same curvature. This may therefore be taken as a sufficient indication of the equicurve circle; the character peculiarly assured to it by the nature of evolution. It must be noted, however, that the curve is supposed to have its concavity in the vicinity of the contact turned all the same way. For if the contact be in a point of contrary fluxure, even a straight line will both touch and cut it in that point.

The reader cannot but remark, that MK is always the chord of a circle touching TE in E, and passing through M.

Let Em be another curve, touching TE in E, such, that the conjugate curve kB, which always gives Tm × Tk = TE², also passes through B. Then, by what has now been demonstrated, the two curves EM and Em have the same equicurve circle ERB, and consequently the same curvature in E. Then, because the rectangles RT × TQ, MT × TK, and mT × Tk, are equal, we have Tm : TM = TK : Tk. Therefore if the arch Bk pass between BK and BQ, the curve Em must pass between the curve EM and the circle ER. Em must therefore have a closer contact with ER than EM has with it; and the smaller the angle QBK is which is contained between the curve and its equicurve circle, the closer is the contact of the curve EM and its equicurve circle ER. Thus the length of the chord EB determines the *magnitude* or degree of curvature at E, when compared with another; and the angle contained between the equicurve circle and the conjugate curve BKF determines the closeness of the contact of the curve with its equicurve circle (the angle TEB being supposed the same in both).

It appears, from the process of demonstration, that the curve EMH falls without or within the equicurve circle according as its conjugate curve BKF does. Also, when BKF cuts BQR, HME also cuts it. But if FQB is on the same side of QB on both sides of the intersection B, the curve HME is also on the same side of it on both sides of the contact E. It is also very clear, that the contact or approach to coalescence between the curve and its circle of curvature, is so much the closer as the conjugate curve BKF comes nearer to the adjoining arch of this circle. It must be the closest of all when KB touches QB, and it must be the least so when KB touches EB, or has EB for an assymptote. The space QBK is a sort of magnified picture of the space MER; and we have a sensible proportion of KQ to TK as the representation of the proportion of TM to TR, quantities which are frequently evanescent and insensible. When QBK is a finite angle, that is, when the tangents of BQ and BK do not coincide, the angle QBK can be measured. But no rectilineal angle can be contained as an unit in the curvilineal angle MER. They are incommensurable, or incomparable. Let the curve KB touch the circle QB without cutting it. This angle is equal incomparable with the former QBK; yet it has a counterpart in MER. This must be incomparable with the former in the same manner; for there is the same proportion between the individuals of both pairs. Thus it appears plainly, that there are curvilineal angles incomparable with each other. Yet are they magnitudes of one kind; because the smallest rectilineal angle must certainly contain them both; and one of them contains the other. But, further, there may be indefinite degrees of this coalescence or closeness of contact between a curve and a circle. The first degree is when the same right line touches both. This is a *simple contact*, and may obtain between any curve and any circle. The next is when EMH and ERB have the same curvature, and when the conjugate curve FKB intersects the circle QB in any assignable angle. This is an *osculation*. The third degree of contact, and second of osculation, is when the curve KB touches the circle QB, but not so as to osculate. The fourth degree of contact, and third of osculation, is when KB and QB have the same curvature or osculate in the first degree of osculation. This gradation of more and more intimate contact, or (more properly speaking) of approximation to coalescence, may be continued without end, "*neque novit natura limitem*," the contact of EM and ER being always two degrees closer than that of BK and BQ. Moreover, in each of those classes of contact there may be indefinite degrees. Thus, when EM and ER have the same curvature, the angle QBK admits of indefinite varieties, each of which ascertains a different closeness of contact at E. Also, though the angle QBK should be the same, the contact at E will be so much the closer the greater the chord EB is.

For TR : TM = TK : TQ

Therefore RM : TR = KQ : KT

Or RM : KQ = TR : TK; = TR × TQ : TK × TQ, = TE² : TK × TQ.

Therefore, when TE is given, RM (which is then the measure of the angle of contact) is proportional to KQ directly, and to the rectangle TK × TQ inversely; and when KQ is given, RM is less in proportion as KT × TQ is greater. In the very neighbourhood of E and B, it is plain that KT × TQ is very nearly equal to EB², and therefore ultimately RM : KQ = ET² : EB².

It will greatly assist our conception of this delicate subject, if we view the origin of these degrees of contact as they are generated by the evolution of lines. A thread evolving from a polygon EDCBA (fig. 13.) describes with its extremity a a line $edbga$, consisting of successive arches of circles united in simple contacts. If it evolve from any continuous curve CBA, after having evolved from the lines ED, BC, the arch cb will be united with the circular arch dc by osculation of the first degree. If any other curve FC touch this evolute in a simple contact, and if the two curves FCBA and DCBA are both evolved, they will touch each other in

Involution. a simple osculation in that point where they have the same radius. If FC touches DC in a simple osculation, the evolved curves will touch in an osculation of the second degree; and, in general, the osculation of the two generated curves is a degree closer than that of their evolutes; and in each state of one of the osculations, there is an indefinite variety of the other, according to the length of its radius of curvature. All this is very clear; and shews, that these degrees of contact do not indicate degrees of curvature, one of which infinitely exceeds another; for they are all finite.

The reader will do well to remark, that the magnitude, which is the subject of the above proportions, which is really of the same kind in them all, and considered as susceptible of various degrees and orders of infinitesimals, is not curvature, but lineal extension. It is RM, the subtense of the angle of contact MER. It is the linear separation from the tangent, or from the equicurve circle. It is, however, usually considered as the measure of curvature, or the proportions of this line are given as the proportions of the curvature. This is inaccurate; for curvature is unquestionably a change of direction only. As this line has generally been the interesting object in the refined study of curve lines, especially in the employment of it in the discussions of mechanical philosophy, it has attracted the whole attention, and the language is now appropriated to this consideration. What is called, by the most eminent mathematicians, variation of curvature, is, in fact, variation of the subtense of the angle of contact. But it is necessary always to distinguish them carefully.

Variation of curvature is the remaining object of our attention.

Curvature is uniform in the circle alone. When the curvature of the arch EMH (fig. 11.) decreases as we recede from E, the arch, being less deflected from its primitive direction ET than the arch ER, must separate less from the line ET, or must fall without the arch ER. The more rapidly its curvature decreases, the describing point must be left more without the circle. It must be the contrary, if its curvature had increased from E toward M. It may change its curve equably or unequably. If equably, there must be a certain uniform rate, which would have produced the same final change of direction in a line of the same length, bending it into the uniformly incurvated arch of a circle. It is not so obvious how to estimate a rate of variation of curvature; and authors of eminence have differed in this estimation. Sir Isaac Newton, who was much interested in this discussion, in his studies on universal gravitation, seems to have adopted a measure which best suited his own views; and has been followed by the greater number. He gives a very clear conception of what he means, by stating what he thinks a case of an invariable rate of variation. This is the equiangular spiral, all the arches of which, comprehended in equal angles from the centre, are perfectly similar, although continually varying in curvature. He calls this a curve EQUABLY VARIABLE, and makes its rate of variation (estimated in that sense in which it is uniform) the measure of the rate of variation in all other curves. Let us see in what respect its variation of curvature is constant. It may be described by the evolution of the same spiral in another position (see fig. 6), and the ratio between the radius of the evolute and that of the evolutrix is always the same; or (which amounts to the same thing) the arch of the evolutrix bears to the evolved arch of the evolute a constant ratio. The curvature of the spiral changes more rapidly in the same proportion as the ratio of the evolved arch to the arch of the evolutrix generated by it is greater, or as it cuts the radii in a more acute angle. These arches may be infinitesimal; therefore the fraction $\frac{\text{fluxion of evolute}}{\text{fluxion of evolutrix}}$ expresses the rate of the variation of curvature in this spiral. Now let $abcd$ (fig. 13.) be any other curve, and ABCD its evolute; let p be the centre of curvature at the point B of the evolute, and Bo the evolved arch; draw the radii pB, po, Bm, on; join pm, and draw Bq perpendicular to pm. It is evident that mn and Bo have the same ratio with Bm and Bp; and that these two small arches may be conceived as being portions of the same equiangular spiral (perhaps in another position), of which q is the centre; and that p is in the curve of another of the same. For $qp : q\text{B} = q\text{B} : q\text{M}, = p\text{B} : \text{B}m$, therefore the ratio of these infinitesimal arches mn and Bo will express the rate of variation in any curve. This is evidently equivalent to saying, that the variation of curvature is proportional to the fluxion of the radius of curvature directly, and the fluxion of the curve inversely. For mn and Bo are ultimately as those fluxions, and $\frac{\text{B}o}{mn}$ is equivalent to $\frac{\dot{r}}{\dot{z}}$, where z is the arch of the spiral, and r the evolved radius of the other. Accordingly, this is the enunciation of the INDEX OF VARIATION given by Newton (See Newton's Fluxions, Prob. VI. § 3.). Therefore, what Newton calls a uniform variation of curvature, is not an increase or diminution by equal arithmetical differences, but by equal proportions of the curvature in every point. The variation of curvature in similar points of similar arches is supposed to be the same.

It is evident that this ratio is the same with that of radius to the tangent of the angle pmB, or of 1 to its tabular tangent. The tangent therefore of this angle corresponding to any point of a curve is the measure of the variation of curvature in that point. Now it may be shewn (and it will appear by and bye), that the fluxion of TK in fig. 11. or the ultimate value of KQ, is always $\frac{2}{3}$ds of the fluxion of the radius of curvature. Therefore the tangent of the angle QBK is always $\frac{2}{3}$ds of that of pmB; and therefore the angle QBK, which we have seen to be an index of the closeness of contact, is also the index of the variation of curvature (See *M'Laurin*, § 386.).

Sir Isaac Newton has given specimens of the use of this measure in a variety of geometrical curves, by means of a general expression of $\frac{\dot{r}}{\dot{z}}$. Thus, in the curve ABC (fig. 8.), let AB be — AD $= x$, DB $= y$ BN $= r$, and BE $= p$; we have $\frac{\text{N}n}{\text{B}b} = \frac{\dot{r}}{\dot{z}}$. Now DB : BE $= y : p, = \text{D}d : \text{B}b, = \dot{x} : \dot{z}$. Therefore $\dot{z} = \frac{p\dot{x}}{y}$, and $\frac{\dot{r}}{\dot{z}} = \frac{y\dot{r}}{p\dot{x}}$. Now, in every curve which we can express by an equation, we can obtain all these quantities p, y, r, and z, and can therefore obtain the measure of

Evolution. of the variation of curvature. It is alfo deferves particular notice, that this inveftigation of $\frac{\dot r}{\dot z}$ is equivalent with finding the centre and radius of curvature of the evolute, by which the curve under confideration is generated; or with finding the centre q (fig. 13.) of an equiangular fpiral, which will touch our curve in m, its evolute in B, and the evolute of the evolute in p, if put into different pofitions when neceffary. This leads to very curious fpeculations, for which, however, we have no room. It has been faid, for inftance, that the curvature at the interfection of a cycloid with its bafe is infinitely greater than that of any circle. If the evolution of the cycloid begin from this point, the curvature of its evolutrix will be infinitely greater ftill upon the fame principles; and we fhall have one infinitely greater than this by evolving it. Yet all thefe infinites, multiplied to infinity, are contained in the central point of every equiangular fpiral! In like manner, there are evolutrixes which coincide with a ftraight line, and others of infinitely greater rectitude, and ftill they are curves. Can this have any meaning? And can it be reconciled with the legitimate reafoning from the fame principles, that all thefe curvatures and angles of contact are producible by evolution; and that they may be, and certainly are every day defcribed, by bodies moving in free fpace, and acted on by accelerating forces directed to different bodies?

The parabola (conical) is the moft fimple of all the lines of unequably varying curvature, and becomes a very good ftandard of comparifon. In the parabola ABC (fig. 8.) let the parameter be $2a$. The equation is then $2ax = y^2$; DE $= a$; p, or BE $= \sqrt{a^2+y^2}$ DQ $= a + 2x$ (by what was formerly demonftrated). Moreover, DB : BE = DQ : BN; and BN $= \frac{pa+2px}{a} = r$. Thefe equations give $2a\dot x = 2y\dot y = 2p\dot p$; and $\frac{a\dot p + 2x\dot p + 2p\dot x}{a} = \dot r$. Now making $\dot x = 1$, and reducing the equations, we obtain $\dot y = \frac{a}{y}$; $\dot p = \frac{y\dot y}{p} = \frac{a}{p}$; and $\dot r = \frac{a\dot p + 2x\dot p + 2p}{a}$.

With thefe values of $\dot y, \dot p, \dot r$, we obtain a numerical value of $\frac{y\dot r}{p}$ moft readily. Thus, in order to obtain the index of variation of curvature in the point where the ordinate at the focus cuts the parabola, make $a = 1$. Then $2x = y^2$; $x = \frac{1}{2}$, $y\ (= \sqrt{2x}) = 1$; $\dot y \left(= \frac{a}{y}\right) = 1$; $p\ (= \sqrt{a^2+y^2}) = \sqrt{2}$; $\dot p \left(= \frac{a}{p}\right) = \sqrt{\frac{1}{2}}$, and $\dot r \left(= \frac{a\dot p + 2x\dot p + 2p}{a}\right) = \sqrt{2} \times 3$. Therefore $\frac{y\dot r}{p} = 3$, = the index of variation in the point B when D is the focus of the parabola; that is to fay, the fluxion of the radius of curvature is three times the fluxion of the curve.

The index of variation, where the ordinate is equal to the parameter, is had by making $x = 2$. This gives Involution. $y = 2$; $\dot y = \frac{1}{2}$; $p = \sqrt{5}$; $\dot p = \sqrt{\frac{1}{5}}$, and $\dot r = 3\sqrt{5}$. Wherefore $\frac{y\dot r}{p} = 6$, which is the index of variation. Moreover, fince $\dot p$ and $\dot r$ are in a conftant ratio, it appears that the index of variation of curvature in the parabola is proportional to the ordinate y. It is always $= 6\,\frac{\text{ordinate}}{\text{parameter}}$; and thus, with very little trouble, we can defcribe the evolute of its evolute, *i. e.* of the femicubical parabola.

In like manner, it may be fhewn, that in all the conic fections $\frac{\dot r}{\dot z}$ is always proportional to the rectangle of the ordinate DB and the fubnormal DE, or to DB × DE. In the parabola, whofe equation is $2ax = y^2$, we have $\frac{\dot r}{\dot z} = \frac{3y}{a}$. In an ellipfe, whofe equation is $2ax - bx^2 = y^2$, we have $\frac{\dot r}{\dot z} = \frac{3 - 3b}{a} \times$ DB × DE, and in the hyperbola, whofe equation is $2ax + bx^2$, $\frac{\dot r}{\dot z}$ is $= \frac{2 + 3b}{a} \times$ DB × DE. This ratio, in all the three fections, is always as the tangent of the angle contained between the diameter and the normal at the point of contact. By this we may compare them with a parabola. In the cycloid at the point E (fig. 5.) $\frac{\dot r}{\dot z}$ is = tan. ∠ EKM, &c. &c.

All thefe things may be traced in the obfervations made on fig. 11. and 12. When the angle BEF is a right angle, the angle KBQ indicates it directly, its tangent being always $= \frac{2}{3}\frac{\dot r}{\dot z}$. It is eafy alfo to fee, that when the curve EMH is a parabola, the line BKF is a ftraight line parallel to EF. It is alfo plain, that by the fame fteps that we proved that no circle can pafs between this parabola and its equicurve circle FRB, fo no other parabola can pafs between them. Indeed the fame reafoning will prove that no curve of the fame kind can pafs between any curve and its ofculating circle. In many cafes, it is more eafy to reafon from the curvature of a curve, by comparing it with an equicurve parabola than with an equicurve circle; particularly in treating of the curvilineal motions of bodies in free fpace, actuated by deflecting forces.

If EMH be an ellipfe or hyperbola, BKF is another ellipfe or hyperbola (*M'Laurin*, § 373.)

We have thus endeavoured to introduce our readers into this curious branch of fpeculative geometry. An introduction is all that can be expected from a work of this kind. We have enlarged on particular points, in proportion as we thought that the notions entertained on the fubject were inadequate, or even vague and indiftinct; and we hope that fome may be incited to acquire clearer conceptions by going to the fountain head. We conclude, by recommending to the young geometer the perufal of the Fluxions of Sir Ifaac Newton,

after he has read [illegible]'s Chapter with care. He will probably be surprised and delighted with seeing the whole compressed by a master's hand into such narrow compass with such beautiful perspicuity.

JOAN D' ARC, the maid of Orleans, has been variously characterised; but all now agree, that she was worthy of a better fate than the horrid death she was doomed to die. (See JOAN *d'Arc, Encycl.*). But did she actually die that death? An ingenious writer in the *Monthly Magazine* has proved, we think, that she did not.

The bishop of Beauvais (says he) is accused by all parties of treachery and trick in the conduct of the trial: it was his known propensity to gain his ends by stratagem, craft, manœuvre, fraud, dexterity. He seeks out, and brings forward, such testimony only as relates to ecclesiastical offences, and then hands over the decision to the secular judges, whose clemency he invokes. Joan says to him publicly, "You * *promised* to restore me to the church, and you deliver me to my enemies." The intention of the bishop, then, must have been, that the secular judges, for want of evidence, should see no offence against the state; as the clerical judges, notwithstanding the evidence, had declined to see any against the church. A fatal sentence was, however, pronounced; and the fulfilment of it entrusted to the ecclesiastical authorities. Immediately after the *auto da fe*, one of the executioners ran to two friars, and said, "that he had never been so shocked at any execution, and that the English had built up † a scaffolding of plaster (*un echafaud de platre*) so lofty, that he could not approach the culprit, which must have caused her sufferings to be long and horrid." She was, therefore, by some *unusual* contrivance, kept out of the reach and observation even of the executioners.

Some time after, when public commiseration had succeeded to a vindictive bigotry, a woman appeared at Metz ‡, who declared herself to be Joan of Arc. She was everywhere welcomed with zeal. At Orleans, especially, where Joan was well known, she was received with the honours due to the liberatress of the town. She was acknowledged by both her brothers, Jean and Pierre d'Arc. On their testimony she was married by a gentleman of the house of Amboise, in 1436. At their solicitation her sentence was annulled in 1456. The Parisians, indeed, long remained incredulous: they must else have punished those ecclesiastics, whose humanity, perhaps, conspired with the bishop of Beauvais to withdraw her from real execution down a central chimney of brick and mortar; or, as the executioner called it, a scaffolding of plaster. The king, for the woman seems to have shunned no confrontation, is stated to have received her with these words: "*Pucelle, m'amie, soyez la très bien revenue, au nom de Dieu.*" She is then said to have communicated to him, kneeling, the artifice practised. Can this woman be an impostor? Our author thinks not, and appeals to Voltaire, who, in his prose works, seems willing to allow that she was not, as is too commonly imagined, one of those half-insane enthusiasts, employed as tools to work upon the vulgar; whom the one party endeavoured to cry up as a prophetess, and the other to cry down as a witch; but that she was a real heroine, superior to vulgar prejudice, and no less remarkable by force of mind than for a courage and strength unusual in her sex. This opinion is certainly countenanced by her behaviour in adversity, and during her trial, which was firm without insolence, and exalted without affectation.

JONES (Sir William), who was styled by Johnson the most enlightened of men, was the son of William Jones, Esq; one of the last of those genuine mathematicians, admirers, and contemporaries of Newton, who cultivated and improved the sciences in the present century. Our author was born on the 28th of September 1746, and received his education at Harrow school, under the care of Dr Robert Sumner, whom he has celebrated in an eulogium which will out-last brass or marble. We are told that he was a class fellow with Dr Parr, and at a very early age displayed talents which gave his tutor the most promising expectations, and which have since been amply justified. From Harrow he was sent to University college, Oxford, where the rapidity and elegance of his literary acquisitions excited general admiration; while a temper, ardently generous, and morals perfectly irreproachable, procured him testimonies of the most valuable esteem. The grateful affection which he always cherished for that venerable seat of learning, did as much honour to his sensibility, as Oxford herself has received by enrolling him among the number of her sons.

In the twenty-third year of his age he travelled through France, and resided some time at Nice, where he employed himself very differently from most other young men who make what is called the tour of Europe. *Man*, and the influence of various forms of *government*, were the principal objects of his investigation; and in applying the result of his inquiries to the state of his own country, he mingled the solicitudes of the Patriot with the honest partialities of an Englishman.

Mr Jones's first literary work was a translation into French of a Persian manuscript, entitled "*Histoire de Nadir Shah, connu sous le nom de Thahmas Kuli Khan, Empereur de Perse*," in two vols. 4to; the history of which performance we shall give in his own words: "A great northern monarch, who visited this country a few years ago, under the name of the Prince of Travendal, brought with him an eastern manuscript, containing the life of Nadir Shah, the late sovereign of Persia, which he was desirous of having translated in England. The secretary of state, with whom the Danish minister had conversed upon the subject, sent the volume to me, requesting me to give a literal translation of it in the French language; but I wholly declined the task, alledging for my excuse the length of the book, the dryness of the subject, the difficulty of the style, and chiefly my want both of leisure and ability to enter upon an undertaking so fruitless and so laborious. I mentioned, however, a gentleman, with whom I had not then the pleasure of being acquainted, but who had distinguished himself by a translation of a Persian history, and was far abler than myself to satisfy the king of Denmark's expectations. The learned writer, who had other works upon his hands, excused himself on the account of his many engagements; and the application to me was renewed. It was hinted, that my compliance would be of no small advantage to me at my entrance into life; that it would procure me some mark of distinction which might be pleasing to me; and, above all, that it would be a reflection

Jones. tion upon this country, if the king should be obliged to carry the manuscript into France. Incited by these motives, and principally by the last of them, unwilling to be thought churlish or morose, and eager for the bubble reputation, I undertook the work, and sent a specimen of it to his Danish Majesty; who returned his approbation of the style and method, but desired that the whole translation might be perfectly literal, and the oriental images accurately preserved. The task would have been far easier to me, had I been directed to finish it in Latin; for the acquisition of a French style was infinitely more tedious; and it was necessary to have every chapter corrected by a native of France, before it could be offered to the discerning eye of the public, since in every language there are certain peculiarities of idiom, and nice shades of meaning, which a foreigner can never learn to perfection. But the work, how arduous and unpleasing soever, was completed in a year, not without repeated hints from the secretary's office that it was expected with great impatience by the Court of Denmark." The translation of the History of Nadir Shah was published in the summer of the year 1770, at the expence of the translator; and forty copies upon large paper were sent to Copenhagen; one of them bound with uncommon elegance for the king himself, and the others as presents to his courtiers*.

* Preface to the History of Nadir Shah, 1773.

What marks of distinction our author received, or what fruits he reaped for his labour, he has not thought proper to disclose; but if any dependence is to be placed on common fame, the reward bestowed upon him for this laborious task consisted only in the thanks of his Danish Majesty, and the honour of being enrolled in the Royal Society of Copenhagen. That distinction was indeed accompanied with a letter, recommending the learned translator to the patronage of his own sovereign; but, in the interim, his friend Lord Dartmouth, who was to have delivered it, had resigned his office of secretary of state, and the letter, we are told, was never presented.

There is reason to think, that this early and severe disappointment made a deep impression on his mind, and induced him to renounce the muses for a time, and to apply himself with assiduity to the study of jurisprudence. This we think apparent, from the style in which he writes of his return from the continent, and of the death of his beloved preceptor Dr Sumner.

"When I left Nice, (says he) where I had resided near seven months, and after traversing almost all France, returned to England, I most ardently desired to pass several years more in the study of polite literature; as then, I thought, I might enter into public life, to which my ambition had always prompted me, more mature and prepared: but with this fruit of my leisure, either fortune, or rather Providence, the disposer of all human events, would not indulge my sloth; for on a sudden, I was obliged to quit that very literature to which, from my childhood, I had applied myself; and he who had been the encourager and assistant of my studies, who had instructed, taught, formed me such as I was, or if I am any thing at all, Robert Sumner, within a year after my return, was snatched away by an untimely death (A)."

In 1771 Mr Jones published *Dissertation sur la Literature Orientale*, 8vo, and this was followed by *Lettre à Monsieur A** Du P****, dans laquelle est compris l'Examen de sa Traduction des Livres attribués à Zoroastre*, 8vo. The dissertation offered a favourable specimen of the author's abilities as a linguist and as a critic; and the letter contained a spirited vindication of the university of Oxford, from the very scurrilous reproaches, in which its incompetency in Oriental literature was asserted by the illiberal translator of the supposed works of the Persian philosopher.

In the same year he gave to the public, "A Grammar of the Persian language," 4to, and at the same time proposed to republish Meninski's Dictionary, with improvements from *De Labrosse's Gazophylacium Linguæ Persarum*, and to add in their proper place an Appendix subjoined to Gehanaguire's Persic Dictionary. The Grammar has been found extremely useful, and has

(A) As a specimen of our author's latinity, we subjoin the epitaph on Dr Sumner, which is affixed to the wall of the south transept of Harrow church.

H. S. E.
ROBERTUS SUMNER, S. T. P.
Collegii Regalis apud Cantab. olim Socius,
Scholæ Harroviensis haud ita pridem Archididascalus.
Fuit hoc præstantissimo Viro
Ingenium naturâ peracre, optimarum disciplinis artium sedulo
Excultum, usu diuturno confirmatum, & quodammodo subactum.
Nemo enim aut in reconditis sapientiæ studiis illo subtilior extitit,
Aut humanioribus literis limatior: nemini fere vel felicius
Contigit judicii acumen, vel uberior eruditionis copia.
Egregiis hisce cum dotibus naturæ, tum doctrinæ subsidiis,
Insuper accedebat in scriptis mira ac prope perfecta eloquentia.
In sermone facetiarum lepor plane Atticus, & gravitate suaviter
Aspera urbanitas; in moribus singularis quædam integritas & fides;
Vitæ denique ratio constans sibi, & ad virtutis normam diligenter severeque,
Exculta. Omnibus qui vel amico essent eo, vel magistro usi, doctrinæ,
Ingenii, virtutis triste reliquit desiderium, subitâ, eheu! atque immaturâ
Morte correptus prid. Id. Sept. A. D.
1771, Æt. 41.

has been repeated f[illegible] times that the design of the Dictionary, tho[illegible] an object of [illegible]tional [illegible]tance for want of [illegible]e encouragement was obliged to be laid aside.

In 1772 he published "Poems; consisting chiefly of Translations from the Asiatic Languages. To which are added two Essays; 1. On the Poetry of the Eastern Nations. 2. On the Arts commonly called Imitative," 8vo, which in 1777 he republished with the addition of some Latin Poems, every way worthy of their author. On the 18th June 1773, he took the degree of Master of Arts, and the same year published "The History of the Life of Nadir Shah, King of Persia. Extracted from an Eastern Manuscript, which was translated into French by order of his Majesty the King of Denmark. With an Introduction, containing, 1. A Description of Asia according to the Oriental Geographers. 2. A short History of Persia from the earliest Times to the present Century: And an Appendix, consisting of an Essay on Asiatic Poetry, and the History of the Persian Language. To which are added Pieces relative to the French Translation," 8vo. Our author having at this period determined to study the law as a profession, and to relinquish every other pursuit, our readers will not be displeased with the following extract, relating to this resolution, which concludes the preface to the history now under consideration:

"To conclude; if any essential mistakes be detected in this whole performance, the reader will excuse them, when he reflects upon the great variety of dark and intricate points which are discussed in it; and if the obscurity of the subject be not a sufficient plea for the errors which may be discovered in the work, let it be considered, to use the words of Pope in the preface to his juvenile poems, that there are very few things in this collection which were not written under the age of five-and-twenty: most of them indeed were composed in the intervals of my leisure in the South of France, before I had applied myself to a study of a very different nature, which it is now my resolution to make the sole object of my life. Whatever then be the fate of this production, I shall never be tempted to vindicate any part of it which may be thought exceptionable; but shall gladly resign my own opinions, for the sake of embracing others, which may seem more probable; being persuaded, that nothing is more laudable than the love of truth, nothing more odious than the obstinacy of persisting in error. Nor shall I easily be induced, when I have disburdened myself of two other pieces which are now in the press, to begin any other work of the literary kind; but shall confine myself wholly to that branch of knowledge in which it is my chief ambition to excel. It is a painful consideration, that the profession of literature, by far the most laborious of any, leads to no real benefit or true glory whatsoever. Poetry, science, letters, when they are not made the sole business of life, may become its ornaments in prosperity, and its most pleasing consolation in a change of fortune; but if a man addicts himself entirely to learning, and hopes by that, either to raise a family, or to acquire, what so many wish for, and so few ever attain, an honourable retirement in his declining age, he will find, when it is too late, that he has mistaken his path; that other labours, other studies, are necessary; and that unless he can assert his own independence in active life, it will avail him little to be favoured by the learned, esteemed by the eminent, or commended even by kings. It is [illegible] on the other hand, that no external advantage can make amends for the loss of virtue and integrity which alone give a perfect comfort to him who possesses them. Let a man, therefore, who wishes to enjoy, what no fortune or honour can bestow, the blessing of self approbation, aspire to the glory given to Pericles by a celebrated historian, of being acquainted with all useful knowledge, of expressing what he knows with copiousness and freedom, of loving his friends and country, and of disdaining the mean pursuits of lucre and interest: this is the only career on which an honest man ought to enter, or from which he can hope to gain any solid happiness." Jones.

The next year he published *Poeseos Asiaticæ Commentariorum Libri Sex, cum Appendice; subjicitur Limon, seu Miscellaneorum Liber*, 8vo; and pursuing his purpose of applying to the study of the law, we hear no more of him from the press (except the new edition of his Poems), until the year 1779. In this interval he was called to the bar, and attended Westminster-hall and the Oxford circuit, where he obtained but little business. He was however appointed a commissioner of bankrupts by Lord Bathurst, who is supposed to have intended to exert his interest to procure his nomination to the bench in the East Indies.

He published in this year, "The speeches of Isæus, in causes concerning the law of succession to property at Athens; with a preparatory discourse, notes critical and historical, and a Commentary, 4to." In this valuable work, the talents of the scholar, the critic, and the lawyer, combine to elucidate a very important part of jurisprudence; for, "though deep researches into the legal antiquities of *Greece* and *Rome* (as he observes in his Commentary) are of greater use to scholars and contemplative persons, than to lawyers and men of business; though Bracton and Lyttleton, Coke and Rolle, are the proper objects of our study; yet the ablest advocates, and wisest judges, have frequently embellished their arguments with learned allusions to antient cases; and such allusions, it must be allowed, are often useful, always ornamental; and, when they are introduced without pedantry, never fail to please." The work was dedicated in a style of respectful gratitude to his patron Lord Bathurst.

In the year 1780, we find our author a candidate to represent in parliament the university of Oxford. He had for some time resided but little in the university, and therefore laboured under some disadvantages; but he did not meanly court the support of any man. In a paper, which was circulated on that occasion, his friends, who were numerous, declare, that they have "neither openly solicited, nor intend openly to solicit, votes for Mr Jones within the University itself, because he will never become the instrument of disturbing the calm seat of the Muses, by consenting to any such solicitation for himself or for any man whatever. His own applications have been, are, and will be, confined to those only who have professed a regard for him, *and who have no votes themselves*: the Masters of Arts in a great university, whose prerogative is cool reason and impartial judgment, must never be placed on a level with the voters of a borough, or the freeholders of a county.

Jones

county. Even in proceeding thus far, he does not set the example, but follows it; and his friends would never have printed any paper, if they had not thought themselves justified by the conduct of others.

"For the first and the last time, they beg leave to suggest, that no exertions must be spared by those who, either personally or by reputation, approve the character of Mr Jones; into which, both literary and political, as well as moral, his friends desire and demand the strictest scrutiny. For his university he began early to provoke, and possibly to incur, the displeasure of great and powerful men: For his university he entered the lists with a foul-mouthed and arrogant Frenchman, who had attacked Oxford in three large volumes of misrepresentation and scurrility: For his university he resigned, for a whole year, his favourite studies and pursuits, to save Oxford the discredit of not having one of her sons ready to translate a tedious Persian manuscript. To Oxford, in short, he is known to be attached by the strongest possible ties; and only regrets the necessity of absenting himself from the place in which of all others he most delights, until the event of the present competition shall either convince him that he has toiled in vain as a man of letters, or shall confer on him the greatest reward to which he can aspire. The unavoidable disadvantage of being so late proposed, and the respectable support with which he is now honoured, will secure him in all events from the least disgrace." The application was unsuccessful, chiefly because his own college had fixed upon another candidate, from a persuasion that the immediate appointment of Mr Jones to a seat, then vacant on the bench of judges in India, was morally certain.

The riots of that year gave occasion to another publication of our author, entitled, "An Inquiry into the legal Mode of suppressing Riots; with a constitutional Plan of future Defence," 8vo; and in 1781 he published "An Essay on the Law of Bailments," 8vo, a very masterly treatise, which did great honour to his legal abilities. In this last work he inculcates the necessity of deeply exploring the grounds of the common law; and speaking of Blackstone, (he says) "his commentaries are the most correct and beautiful outline that ever was exhibited of any human science; but they alone will no more form a lawyer, than a general map of the world, how accurately and elegantly soever it may be delineated, will make a geographer."

In this year he likewise recalled his muse in an Ode on the nuptials of Lord Viscount Althorpe, who had been his pupil, to Miss Lavinia Bingham. This beautiful little poem is preserved in the European Magazine for January 1785, and we think in other periodical publications.

From many circumstances which might be collected together, it would appear that our author at this juncture did not coincide in opinion with those who had the direction of government, nor did he approve the measures at that period adopted.—With these sentiments he seems to have been selected as a proper person to be introduced as a member of the Constitutional Society. Could he have foreseen the degeneracy of such associations, there is reason to believe that he would have declined what he condescended to accept as an honour; for though an ardent friend to liberty, he was an enemy to theoretical innovation, and declares in a letter to the secretary, that by the term constitution he understands "the great system of public, in contradistinction to private and criminal law, which comprises all those articles which Blackstone arranges, in his first volume, under the rights of persons, and of which he gives a perspicuous analysis. Whatever then relates to the rights of persons, either absolute rights, as the enjoyment of liberty, security, and property, or relative, that is, in the public relations of magistrates and people, makes a part of that majestic whole, which we properly call the constitution. This constitutional or public law is partly unwritten, and grounded upon immemorial usage, and partly written or enacted by the legislative power; but the unwritten, or common law, contains the true spirit of our constitution: the written has often most unjustifiably altered the form of it; the common law is the collected wisdom of many centuries, having been used and approved by successive generations; but the statutes frequently contain the whims of a few leading men, and sometimes of the mere individuals employed to draw them."

In 1782 he published "The Mahomedan Law of Succession to the Property of Intestates, in Arabic, with a verbal Translation and explanatory Notes," 4to.

At length the post of one of the judges in the East Indies, which had been kept vacant five years, was determined upon being filled up; and our author, on the 4th March 1783, was appointed to that station, and on the 20th received the honour of knighthood. On the 8th of April he married Miss Shipley, eldest daughter of the Bishop of St Asaph, and almost immediately embarked for the Indies. He had previously published "The Moallakat; or, Seven Arabian Poems, which were suspended on the Temple at Mecca, with a Translation and Arguments." 4to. To this it was intended to add a preliminary discourse and notes.—The former to comprise observations on the antiquity of the Arabian language and letters; on the dialects and characters of Himyar and Koraish, with accounts of some Himyarick poets; on the manners of the Arabs in the age immediately preceding that of Mahomed; on the temple at Mecca, and the Moallakat, or pieces of poetry suspended on its walls or gate; lastly, on the lives of the Seven Poets, with a critical history of their works, and the various copies or editions of them preserved in Europe, Asia, and Africa. The latter to contain authorities and reasons for the translation of controverted passages; to elucidate all the obscure couplets, and exhibit or propose amendments of the text; to direct the reader's attention to particular beauties, or point out remarkable defects; and to throw light on the images, figures, and allusions of the Arabian poets, by citations either from writers of their own country, or from such of our European travellers as best illustrate the ideas and customs of Eastern nations. This discourse and the notes have not yet appeared. At his departure for the eastern world, he left, in manuscript, with his brother-in-law the Dean of St Asaph, a little tract, entitled "The Principles of Government, in a Dialogue between a Scholar and a Peasant." This celebrated dialogue being afterwards published by the Dean, and widely circulated by the society for constitutional information, the Dean was

 prosecuted

Jones.

prosecuted for publishing a libel, and, if our memory deceives us not, was found guilty.

Sir William Jones now dropt for ever all concern in party politics, and applied himself to pursuits more worthy of his talents. During his voyage to India, he conceived the idea of the Asiatic Society, of which an account has been given under the title Societies (*Encycl.*), and of whose researches five volumes, replete with much curious information, are now before the public. But ardently as his mind was attached to general literature and science he was by no means inattentive to the professional duties of his high station. He had indeed, to use his own expression, an "undissembled fondness for the study of jurisprudence *;" and in the character of a judge, displayed the profound knowledge and irreproachable integrity, which, before his promotion, pervaded his reasonings as a lawyer, and governed his conduct as a man. Unfortunately the intense ardour of application, which produced his frequent contributions to the stock of human knowledge, added to the unfavourable influence of the climate, greatly impaired his health. On this account, after a residence of about fifteen years in India, he made preparations for returning to England; but death interposed; and this illustrious ornament of science and virtue was taken from the world on the 27th of April 1794, in the 48th year of his age. "It is to the shame of scepticism (as one of his biographers well observes), to the encouragement of hope, and to the honour of genius, that this great man was a sincere believer in the doctrines of Christianity, and that he was found in his closet in the attitude of addressing his prayer to God." We shall give his character as it was drawn by Sir John Shore, Baronet, (now Lord Teignmouth) in a discourse delivered at a meeting of the Asiatic Society, held on the 22d of May 1794.

"His capacity for the acquisition of languages has never been excelled. In Greek and Roman literature, his early proficiency was the subject of admiration and applause; and knowledge of whatever nature, once obtained by him, was ever afterwards progressive. The more elegant dialects of modern Europe, the French, the Spanish, and Italian, he spoke and wrote with the greatest fluency and precision; and the German and Portuguese were familiar to him. At an early period of life his application to Oriental literature commenced; he studied the Hebrew with ease and success; and many of the most learned Asiatics have the candour to avow, that his knowledge of Arabic and Persian was as accurate and extensive as their own; he was also conversant in the Turkish idiom, and the Chinese had even attracted his notice so far as to induce him to learn the radical characters of that language, with a view perhaps to farther improvements. It was to be expected, after his arrival in India, that he would eagerly embrace the opportunity of making himself master of the Sanscrit; and the most enlightened professors of the doctrines of Brahma confess with pride, delight, and surprise, that his knowledge of their sacred dialect was most critically correct and profound. The Pandits, who were in the habit of attending him, could not, after his death, suppress their tears for his loss, nor find terms to express their admiration at the wonderful progress he had made in their sciences.

"Before the expiration of his twenty-second year, he had completed his Commentaries on the Poetry of the Asiatics, although a considerable time afterwards elapsed before their publication; and this work, if no other monument of his labours existed, would at once furnish proofs of his consummate skill in the Oriental dialects, of his proficiency in those of Rome and Greece, of taste and erudition far beyond his years, and of talents and application without example.

"But the judgment of Sir William Jones was too discerning to consider language in any other light than as the key of science, and he would have despised the reputation of a mere linguist. Knowledge and truth were the objects of all his studies, and his ambition was to be useful to mankind; with these views he extended his researches to all languages, nations, and times.

"Such were the motives that induced him to propose to the government of India, what he justly denominated a work of national utility and importance, the compilation of a copious Digest of Hindu and Mahomedan Law, from Sanscrit and Arabic originals, with an offer of his services to superintend the compilation, and with a promise to translate it. He had foreseen, previous to his departure from Europe, that without the aid of such a work, the wise and benevolent intentions of the legislature of Great Britain, in leaving to a certain extent the natives of these provinces in possession of their own laws, could not be completely fulfilled; and his experience, after a short residence in India, confirmed what his sagacity had anticipated, that without principles to refer to, in a language familiar to the judges of the courts, adjudications amongst the natives must too often be subject to an uncertain and erroneous exposition, or wilful misinterpretation of their laws.

"To the superintendance of this work, which was immediately undertaken at his suggestion, he assiduously devoted those hours which he could spare from his professional duties. After tracing the plan of the Digest, he prescribed its arrangement and mode of execution, and selected from the most learned Hindus and Mahomedans fit persons for the task of compiling it: flattered by his attention, and encouraged by his applause, the Pandits prosecuted their labours with chearful zeal to a satisfactory conclusion. The Molavees have also nearly finished their portion of the work; but we must ever regret, that the promised translation, as well as the meditated preliminary dissertation, have been frustrated by that decree, which so often intercepts the performance of human purposes.

"During the course of this compilation, and as auxiliary to it, he was led to study the works of Menu, reputed by the Hindus to be the oldest and holiest of legislators; and finding them to comprise a system of religious and civil duties, and of law in all its branches, so comprehensive and minutely exact, that it might be considered as the Institutes of Hindu Law, he presented a translation of them to the government of Bengal. During the same period, deeming no labour excessive or superfluous that tended in any respect to promote the welfare or happiness of mankind, he gave the public an English version of the Arabic Text of the Sirajiyah or Mahomedan Law of Inheritance, with a Commentary. He had already (as has been observed) published in England a translation of a tract on the same subject by another Mahomedan lawyer, containing, as his own words express, 'a lively and elegant Epitome of the Law of Inheritance of Zaid.'

"To

"To these learned and important works, so far out of the road of amusement, nothing could have engaged his application but that desire which he ever professed, of rendering his knowledge useful to his nation, and beneficial to the inhabitants of these provinces.

"I should scarcely (continues Lord Teignmouth) think it of importance to mention, that he did not disdain the office of editor of a Sanscrit and Persian work, if it did not afford me an opportunity of adding, that the latter was published at his own expence, and was sold for the benefit of insolvent debtors. A similar application was made of the produce of Sirajiyah."

But nothing exhibits the large grasp of Sir William Jones's mind in so striking a point of view as a paper in his own hand-writing, which came into Lord Teignmouth's possession after his death. It was intitled DESIDERATA, and proposed for investigation the following subjects relating to the eastern world.

India.—1. The ancient geography of India, &c. from the Puranas. 2. A botanical description of Indian plants, from the Cosha, &c. 3. A grammar of the Sanscrit language, from Panini, &c. 4. A dictionary of the Sanscrit language, from the 32 original vocabularies and Niructi. 5. On the ancient music of the Indians. 6. On the medical substances of India, and the Indian art of medicine. 7. On the philosophy of the ancient Indians. 8. A translation of the Veda. 9. On ancient Indian geometry, astronomy, and algebra. 10. A translation of the Puranas. 11. A translation of the Mahabbara and Ramayan. 12. On the Indian theatre, &c. &c. 13. On the Indian constellations, with their mythology, from the Puranas. 14. The history of India before the Madomedan conquest, from the Sanscrit Cashmir Histories.

Arabia.—15. The history of Arabia before Mahomed. 16. A translation of the Hamasa. 17. A translation of Hariri. 18. A translation of the Facabatul Khulafa. Of the Cafiah.

Persia.—19. The history of Persia, from authorities in Sanscrit, Arabic, Greek, Turkish, Persian ancient and modern, Firdausi's Khosrau nama. 20. The five poems of Nizami, translated in prose. 21. A dictionary of pure Persian Je changire.

China.—22. A translation of Shi-cing. 23. The text of Can-fu-tsu, verbally translated.

Tartary.—24. A history of the Tartar nations, chiefly of the Moguls and Othmans, from the Turkish and Persian.

"We are not authorised (says his Lordship) to conclude, that he had himself formed a determination to complete the works which his genius and knowledge had thus sketched; the task seems to require a period beyond the probable duration of any human life; but we, who had the happiness to know Sir William Jones; who were witnesses of his indefatigable perseverance in the pursuit of knowledge, and of his ardour to accomplish whatever he deemed important; who saw the extent of his intellectual powers, his wonderful attainments in literature and science, and the facility with which all his compositions were made—cannot doubt, if it had pleased Providence to protract the date of his existence, that he would have ably executed much of what he had so extensively planned."

We have already enumerated attainments and works which, from their diversity and extent, seem far beyond the capacity of the most enlarged minds; but the catalogue may yet be augmented. To a proficiency in the languages of Greece, Rome, and Asia, he added the knowledge of the philosophy of those countries, and of every thing curious and valuable that had been taught in them. The doctrines of the Academy, the Lyceum, or the Portico, were not more familiar to him than the tenets of the Vedas, the mysticism of the Sufis, or the religion of the ancient Persians; and whilst, with a kindred genius, he perused with rapture the heroic, lyric, or moral compositions of the most renowned poets of Greece, Rome, and Asia, he could turn with equal delight and knowledge to the sublime speculations or mathematical calculations of Barrow and Newton. With them also he professed his conviction of the truth of the Christian religion; and he justly deemed it no inconsiderable advantage, that his researches had corroborated the multiplied evidence of Revelation, by confirming the Mosaic account of the primitive world.

In his eighth anniversary discourse to the Asiatic Society, he thus expresses himself: "Theological inquiries are no part of my present subject; but I cannot refrain from adding, that the collection of tracts which we call, from their excellence, the Scriptures, contain, independently of a divine origin, more true sublimity, more exquisite beauty, purer morality, more important history, and finer strains both of poetry and eloquence, than could be collected within the same compass from all other books that were ever composed in any age, or any idiom. The two parts, of which the Scriptures consist, are connected by a chain of compositions, which bear no resemblance in form or style to any that can be produced from the stores of Grecian, Indian, Persian, or even Arabian learning; the antiquity of these compositions no man doubts, and the unstrained application of them to events long subsequent to their publication, is a solid ground of belief that they were genuine predictions; and consequently inspired."

There were, in truth, few sciences in which he had not acquired considerable proficiency; in most, his knowledge was profound. The theory of music was familiar to him; nor had he neglected to make himself acquainted with the interesting discoveries lately made in chemistry; "and I have heard him (says Lord Teignmouth) assert, that his admiration of the structure of the human frame had induced him to attend for a season to a course of anatomical lectures, delivered by his friend the celebrated Hunter."

His last and favourite pursuit was the study of botany, which he originally began under the confinement of a severe and lingering disorder, which with most minds would have proved a disqualification from any application. It constituted the principal amusement of his leisure hours. In the arrangements of Linnæus, he discovered system, truth, and science, which never failed to captivate and engage his attention; and from the proofs which he has exhibited of his progress in botany, we may conclude that he would have extended the discoveries in that science.

It cannot be deemed useless or superfluous to inquire by what arts or method he was enabled to attain to a degree of knowledge almost universal, and apparently beyond the powers of man, during a life little exceeding 47 years.

The faculties of his mind, by nature vigorous, were improved

in pro[illegible] and exce[illegible] memory, by habitual practice, had acquired a capacity of retaining whatever had once been impressed upon it. To an unextinguished ardour for universal knowledge, he joined a perseverance in the pursuit of it which subdued all obstacles; his studies began with the dawn, and, during the intermissions of professional duties, were continued throughout the day; reflection and meditation strengthened and confirmed what industry and investigation had accumulated. It was a fixed principle with him, from which he never voluntarily deviated, not to be deterred by any difficulties that were furmountable from profecuting to a fuccefsful termination what he had once deliberately undertaken.

But what appeared more particularly to have enabled him to employ his talents fo much to his own and the public advantage, was the regular allotment of his time, and a fcrupulous adherence to the diftribution which he had fixed; hence all his ftudies were purfued without interruption or confufion. He collected information, too, from every quarter; juftly concluding, that fomething might be learned from the illiterate, to whom he liftened with the utmoft candour and complacency.

Lord Teignmouth, addreffing himfelf to the Afiatic Society, fays, "Of the private and focial virtues of our lamented Prefident, our hearts are the beft records. To you who knew him, it cannot be neceffary for me to expatiate on the independence of his integrity, his humanity, probity, or benevolence, which every living creature participated; on the affability of his converfation and manners, or his modeft, unaffuming deportment: nor need I remark, that he was totally free from pedantry, as well as from arrogance and felf-fufficiency, which fometimes accompany and difgrace the greateft abilities. His prefence was the delight of every fociety, which his converfation exhilarated and improved; and the public have not only to lament the lofs of his talents and abilities, but that of his example.

"To him, as the founder of our inftitution, and whilft he lived its firmeft fupport, our reverence is more particularly due. Inftructed, animated, and encouraged by him, genius was called forth into exertion, and modeft merit was excited to diftinguifh itfelf. Anxious for the reputation of the Society, he was indefatigable in his own endeavours to promote it, whilft he cheerfully affifted thofe of others. In lofing him, we have not only been deprived of our brighteft ornament, but of the guide and patron, on whofe inftructions, judgement, and candour, we could implicitly rely." Though thefe are the fentiments, not only of Lord Teignmouth, but, we believe, of every man of letters, we truft there is ftill left in Bengal a fufficient love of letters and of fcience to carry on the plan which was formed by the genius of Sir William Jones.

JONESIA, is a very handfome middling-fized ramous tree, found in gardens about Calcutta. In the Sanfcrit it is called *As'oca*, and in the Bengalefe *Ruffock*; but the name Jonefia was given to it by the Afiatic Society, who confecrated it to the memory of their firft prefident Sir William Jones. It is thus defcribed by Dr Roxburgh, a member of that fociety:

"*Calyx*, two leaved, corol, one petaled, piftil-bearing; bafe of the tube impervious; ftamens long, afcending, inferted into the margin of a glandulous nectarial ring, which crowns the mouth of the tube, the uppermoft two of which more diftant; ftyle declining. *Legume* turgid. *Trunk* erect, though not very ftraight. *Bark* dark brown, pretty fmooth. *Branches* numerous, fpreading in every direction, fo as to form a moft elegant fhady head. *Leaves* alternate, abruptly feathered, feffile, generally more than a foot long; when young pendulous and coloured. *Leaflets* oppofite, from four to fix pair, the lowermoft broad lanced, the upper lanced; fmooth, fhining, firm, a little waved, from four to eight inches long. *Petiole* common, round, and fmooth. *Stipule* axillary, folitary; in fact a procefs from the bafe of the common petiole, as in many of the graffes and monandrifts, &c. *Umbels* terminal and axillary; between the ftipule and branchlet, globular, crowded, fubfeffile, erect. *Bracts*, a fmall hearted one under each divifion of the umbel. *Peduncle* and pedicles fmooth, coloured. *Flowers* very numerous, pretty large; when they firft expand they are of a beautiful orange colour, gradually changing to red, forming a variety of lovely fhades; fragrant during the night. *Calyx* perianth, below two-leaved, leaflets fmall, nearly oppofite, coloured, hearted, bracte like, marking the termination of the pedicel, or beginning of the tube of the corol. *Corol* one petalled, funnel-form; tube flightly incurved, firm, and flefhy, tapering towards the bafe (club funnel-fhaped) and there impervious; border four parted; divifion fpreading, fuborbicular; margins moft flightly woolly: one third the length of the tube. *Nectary*, a ftimeniferous and piftiliferous ring crowns the mouth of the tube. *Stamens*, filaments generally feven; and feven muft, I think, be the natural number; viz. three on each fide, and one below, above a vacancy, as if the place of an eighth filament, and is occupied on its infide by the piftil; they are equal, diftinct, afcending, from three to four times longer than the border of the corol. *Anthers* uniform, fmall, incumbent. *Piftil*, germ oblong, pediceled; pedicel inferted into the infide of the nectary, immediately below the vacant fpace already mentioned; ftyle nearly as long as the ftamens, declining; ftigma fimple. *Pericarp*, legume fcimeter-formed, turgid, outfide reticulated, otherwife pretty fmooth; from fix to ten inches long, and about two broad. *Seeds* generally from four to eight, fmooth; grey, fize of a large chefnut."

Jonefia, Jooth.

The Jonefia flowers at the beginning of the hot feafon, and its feeds ripen during the rains. The plants and feeds were originally brought to Calcutta from the interior parts of the country, where it is indigenous. *N. B.* Many of the flowers have only the rudiment of a piftil. In Plate XXX. A is a branchlet of the natural fize. B, A fingle flower a little magnified; *a a* the calyx. C, A fection of the fame, exhibiting four of the ftamens, 1 1 1 1 the piftil 2, and how far the tube is perforated. D, A fimilar fection of one of the abortive flowers; 3 is the abortive piftil. E, The ripe legume opening near the bafe, natural fize. *Note*, The fpace between the *b* and *c* marks the original tube of the coral. F, One of the feeds, natural fize. G, The bafe of the common petiole, with its ftipule; *a a*, the petioles of the lower pair of leaflets.

JOOTSI-SIMA, a fmall flat ifland, which is feparated from Cape Nota in Japan by a channel about five leagues wide. Its circumference does not exceed two leagues; it is well wooded, of an agreeable afpect, and well inhabited. Peroufe, who failed round it, remarked from the quarter-deck of his fhip fome confiderable edifices between the houfes of the inhabitants; and hard

Journals. Joyst.

hard by a fort or castle at the south-west point of the island, he [illegible] some gibbets. He does not, however, affirm that these gibbets were for the execution of criminals, for, as he observes, it would be [illegible] much if the Japanese, whose customs are so different from ours [illegible] in this point to resembles us so nearly. He re[illegible]s the island as surrounded with dreadful breake[rs] [illegible] the distance of a league and a half from which, he had constantly 60 fathoms, with rocky bottom. He places the island (differently, according to the editor of his voyage, from all other geographers) in latitude 37° 51′ north, and in Long. 135° 20 east from Paris.

JOURNALS, the title of periodical publications. See *Encyclopædia*. The principal British Journals are: *The History of the Works of the Learned*, begun at London in 1699. *Censura Temporum*, in 1708. About the same time there appeared two new ones; the one under the title of *Memoirs of Literature*, containing little more than an English translation of some articles in the foreign Journals, by M. de la Roche; the other, a collection of loose tracts, intitled, *Bibliotheca Curiosa*, or a Miscellany. These, however, with some others, are now no more, but are succeeded by the *Annual Register*, which began in 1758; the *New Annual Register*, begun in 1780; the *Monthly Review*, which began in the year 1749, and gives a character of all English literary publications, with the most considerable of the foreign ones: the *Critical Review*, which began in 1756, and is nearly on the same plan: as also the *London Review*, by Dr Kenrick, from 1775 to 1780; *Maty's Review*, from Feb. 1782 to Aug. 1786; the *English Review*, begun in Jan. 1783; and the *Analytical Review*, begun in May 1788, dropt in 1798, and revived in 1799, under the title of the *New Analytical Review*; but again dropt after two or three months trial: the *British Critic*, begun in 1792, and still carried on with much spirit and ability: the *Anti-Jacobin Review and Magazine*, commenced in 1798, for the meritorious purpose of counteracting the pernicious tendency of French principles in politics and religion: the *New London Review*, January 1799: *A Journal of Natural Philosophy, Chemistry, and the Arts*, which was begun in 1797 by Mr Nicholson, and has been conducted in such a manner, that it is one of the most valuable works of the kind to be found in any language: the *Philosophical Magazine*, begun in 1798 by Mr Tilloch, and carried on upon much the same plan, and with much the same spirit, as Nicholson's Journal.

Besides these, we have several monthly pamphlets, called *Magazines*, which, together with a chronological series of occurrences, contain letters from correspondents, communicating extraordinary discoveries in nature and art, with controversial pieces on all subjects. Of these, the principal are those called the *Gentleman's Magazine*, which began with the year 1731; the *London Magazine*, which began a few months after, and has lately been discontinued; the *Universal Magazine*, which is nearly of as old a date; the *Scotch Magazine*, which began in [1]739, and is still continued; the *European Magazine*; and the *Monthly Magazine*, a miscellany of much information, but not of [illegible]d principles.

JOYST or Jeyst, the second month of the Bengal year.

IRPATTOBAT, Membranes or [illegible], are the [illegible] same as *[illegible]* [illegible] ALGEBRA, *Encycl.*

Irreducible.

IRREDUCIBLE Case, in algebra, is used for that case of cubic equations where the root, according to Cardan's rule, appears under an impossible or imaginary form, and yet is real.

It is remarkable that this case always happens, *viz.* one root, by Cardan's rule, in an impossible form, whenever the equation has three real roots, and no impossible ones, but at no time else.

If we were possessed of a general rule for accurately extracting the cube root of a binomial radical quantity, it is evident we might resolve the irreducible case generally, which consists of two of such cubic binomial roots. But the labours of the algebraists, from Cardan down to the present time, have not been able to remove this difficulty. Dr Wallis thought that he had discovered such a rule; but, like most others, it is merely tentative, and can only succeed in certain particular circumstances.

IRON, is by much the most useful of all the metals, as has been sufficiently proved under the article Iron, *Encycl.* and under Chemistry in this *Supplement.* The word is again introduced here, because it affords us an opportunity of laying before our readers some valuable observations by Chaptal on the use of the *oxyds* of iron in dyeing cotton.

"The oxyd of iron has such an affinity for cotton thread, that if the latter be plunged in a saturated solution of iron in any acid whatever, it immediately assumes a chamoy yellow colour, more or less dark, according to the strength of the liquors. It is both a curious and easy experiment, that when cotton is made to pass through a solution of the sulphat of iron, rendered turbid by the oxyd which remains suspended in the liquor, it will be sufficient to dip the cotton in the bath to catch the last particle of the oxyd, and to restore to the liquor the transparency it has lost. The solution, then, which before had a yellowish appearance, becomes more or less green, according as it is more or less charged.

"The colour given to cotton by the oxyd of iron becomes darker, merely by exposure to the air; and this colour, soft and agreeable when taken from the bath, becomes harsh and ochry by the progressive oxydation of the metal. The colour of the oxyd of iron is very fast: it resists not only the air and water, but also alkaline leys, and soap gives it splendour without sensibly diminishing its intensity. It is on account of these properties that the oxyd of iron has been introduced into the art of dyeing, and been made a colouring principle of the utmost value.

"In order that the oxyd of iron may be conveniently applied to the cotton thread, it is necessary to begin by effecting its solution; and, in this case, acids are employed as the most useful solvents. Dyers almost everywhere make a mystery of the acid which they employ; but it is always the acetous, the sulphuric, the nitric, or the muriatic. Some of them ascribe great differences to the solution of iron by the one or the other acid; but, in general, they give the preference to the acetous. This predilection appears to be founded much less on the difference of the colours that may be communicated by the one or the other salt, than on the different degrees of corrosive power which each exercises on the stuff. That of the sulphat and muriat is so great,

that if the stuff be not washed when it comes from the bath, it will certainly be burnt; whereas solutions by the acetous, or any other vegetable acid, are not attended with the like inconvenience.

"Iron appears to be at the same degree of oxydation in the different acids, since it produces the same shade of colour when precipitated; and any acid solvent may be employed indiscriminately, provided the nature of the salt, and the degree of the saturation of the acid, be sufficiently known; for the subsequent operations may be then directed according to this knowledge, and the inconveniences which attend the use of some of these salts may be prevented. This, without doubt, is a great advantage which the man of science enjoys over the mere workman, who is incapable of varying his process according to the nature and state of the salts which he employs.

"1. If the sulphat of iron, or any other martial salt, be dissolved in water, and cotton be dipped in the liquid, the cotton will assume a chamoy colour, more or less dark according as the solution is more or less charged. The affinity of the cotton to the iron is so great, that it attracts the metal, and takes it in a great measure from the acid by which it was dissolved.

"2. If the iron of a pretty strong solution be precipitated by an alkaline liquor that shews five or six degrees (by the areometer of Baumé), the result will be a greenish blue magma. The cotton macerated in this precipitate assumes at first an unequal tint of dirty green; but mere exposure to the air makes it in a little time turn yellow, and the shade is very dark.

"It is by such, or almost similar processes, that dyers communicate what is called among workmen an *ochre* or *rust colour*. But these colours are attended with several inconveniences to the artist: 1. Strong shades burn or injure the cloth: 2. This colour is harsh, disagreeable to the eye, and cannot be easily united with the mild colours furnished by vegetables."

To avoid these inconveniences, our author made several attempts, which led him to the following practice: He treads the cotton cold in a solution of the sulphat of iron, marking three degrees; he wrings it carefully, and immediately plunges it in a ley of potash at two degrees, upon which he has previously poured to saturation a solution of the sulphat of alumine: the colour is then brightened, and becomes infinitely more delicate, soft, and agreeable. The sulphat no longer attacks the tissue of the stuff; and after the cotton has been left in the bath for four or five hours, it is taken out to be wrung, washen, and dried. In this manner we may obtain every shade that can be wished, by graduating the strength of the solutions. This simple process, the theory of which presents itself to the mind of every chemist, has the advantage of furnishing a colour very agreeable, exceedingly fixed, and, above all, extremely economical. He employs it with great advantage in dyeing nankeens, as it has the property of resisting leys. It becomes brown, however, by the action of astringents.

M. Chaptal made several attempts to combine this yellow with the blue of indigo, in order to obtain a durable green; but as they were all unsuccessful, he infers that there is not a sufficient affinity between the blue of indigo and the oxyds of iron. He found that these oxyds, on the other hand, combine very easily with the red of madder, and produce a bright violet or plum colour, the use of which is as extensive as beneficial in the cotton manufactory. But if we should confine ourselves to apply these two colours to cotton, without having employed a mordant capable of fixing the latter, the colour would not only remain dull and disagreeable by the impossibility of brightening it, but it would still be attended with the great inconvenience of not resisting leys. We must begin, then, by preparing the cotton as if to dispose it for receiving the Adrianople red; and when it has been brought to the operation of galling, it is to be passed through a solution of iron, more or less charged, according to the nature of the violet required: it is then to be carefully washed, twice maddered, and brightened in a bath of soap.

When a real velvety rich violet is required, it is not to be passed through the solution of iron till it has been previously galled; the iron is then precipitated in a bluish oxyd, which, combined with the red of madder, gives a most brilliant purple, more or less dark according to the strength of the galling and of the ferruginous solution. It is very difficult to obtain an equal colour by this process; and in manufactories, an equal violet is considered as a master-piece of art. It is generally believed, that it is only by well-directed manipulations that it is possible to resolve this problem, of so much importance in dyeing. But I am convinced (says our author), that the great cause of the inequality in this dye is, that the iron deposited on the cotton receives an oxydation merely by exposure to the air, which varies in different parts of it. The threads which are on the outside of the hank are strongly oxydated, while those in the inside, removed from the action of the air, experience no change. It thence follows, that the inside of the hank presents a weak shade, while the exterior part exhibits a violet almost black. The means to remedy this inconvenience is, to wash the cotton when it is taken from the solution of iron, and to expose it to the madder moist. The colour will become more equal and velvety. The solvents of iron are almost the same for this colour as for the yellow colour already mentioned.

The following observation may serve to guide the artist in brightening the violet on his cotton. The red of madder and the oxyd of iron deposited on the stuff determine the violet colour. This colour becomes red or blue, according as either of the principles predominates. The dyer knows by experience how difficult it is to obtain a combination which produces the tone of colour desired, especially when it is required to be very full, lively, and durable. This object, however, may be obtained, not only by varying the proportions of the two colouring principles, but also by varying the process of brightening. The only point is to be acquainted with the two following facts; that the soda destroys the iron, while the soap, by strong ebullition, seizes in preference the red of the madder. Hence it is, that the colour may be inclined to red or blue, according as you brighten with one or the other of these mordants. Thus, cotton taken from the madder dye, when washed and boiled in the brightening liquor with $\frac{1}{25}$ths of soap, will give a superb violet; whereas you will obtain only a plum colour in treating it with soda.

The oxyd of iron precipitated on any stuff unites also very advantageously with the fawn colour furnished

by astringents; and by varying the strength of mordants, an infinity of shades may be produced. In this case, it is less a combination or solution of principles than the simple mixture or juxta-position of the colouring bodies on the stuff. By means of a boiling heat, we may combine, in a more intimate manner, the oxyd of iron with the astringent principle; and then it is brought to the state of black oxyd, as has been observed by Berthollet. It is possible also to embrown these colours, and to give them a variety of tints, from the bright grey to the deep black, by merely passing the cottons impregnated with the astringent principle thro' a solution of iron. The oxyd is then precipitated itself by the principle which is fixed on the stuff.

An observation, which may become of the utmost value for the art of dyeing, is, that the most usual astringent vegetables all furnish a yellow colour, which has not much brilliancy, but which has sufficient fixity to be employed with advantage. This yellow colour is brightened in the series of vegetables, in proportion as the astringent principle is diminished, and the vivacity of the colour is augmented in the same proportion. It is difficult, then, to obtain yellow colours which are at the same time durable and brilliant. These two valuable qualities are to each other in an inverse ratio; but it is possible to unite the colouring principles in such a manner as to combine splendour with fixity. Green oak bark unites perfectly with yellow weed, and sumach with green citron. It is by this mixture that we may be able to combine with the oxyd of iron vegetable colours, the splendour of which is equal to their durability.

Our author concludes his observations with cautioning the dyer against substituting sumach and the bark of the alder tree or oak for gall when dyeing cotton red. "I can safely assert (says he), that it is impossible to employ these as substitutes, in whatever doses they may be used. The colour is always much paler, poorer, and less fixed. I know that the case is not the same in regard to dyeing wool and silk, in which it may be employed with success; and in giving an account of this difference, I think the cause of it may be found in the nature of the gall-nuts. 1. The acid which they exclusively contain, as Berthollet has proved, facilitates the decomposition of the soap with which the cottons have been impregnated, and the oil then remains fixed in their tissue, and in a greater quantity, as well as in a more intimate combination. 2. The gall-nuts, which owe their development to animal bodies, retain a character of animalisation, which they transmit to the vegetable stuff, and by these means augment its affinities with the colouring principle of the madder; for it is well known of what utility animal substances are to facilitate this combination. This animalisation becomes useless in operating upon woollen or silk."

JUAN DE FUCA, a celebrated strait on the north-west coast of America, was surveyed by Captain Vancouver in the Discovery sloop of war, with a view to ascertain whether it leads to any communication between the North Pacific and the North Atlantic Oceans. As they advanced within the opening of the strait, their progress was greatly retarded by the number of inlets into which the entrance branched in every direction; and most of these were examined by the boats, which were frequently absent from the ships on this service for several days together. In the midst of their labours, they were surprised by the sight of two Spanish vessels of war, employed, like themselves, in surveying this inlet, the examination of which had been begun by them in the preceding year. Measures of mutual assistance were concerted between the captains of the two nations for the prosecution of the survey, in which each agreed to communicate to the other their discoveries. Not one of the many arms of the inlet, nor of the channels which they explored in this broken part of the coast, was found to extend more than 100 miles to the eastward of the entrance into the strait. After having surveyed the southern coast, on which side a termination was discovered to every opening, by following the continued line of the shore, they were led to the northward, and afterward towards the north-west, till they came into the open sea through a different channel from the strait of Juan de Fuca, by which they had commenced this inland navigation.

Thus it appeared, that the land forming the north side of that strait is part of an island, or of an archipelago, extending nearly 100 leagues in length from S. E. to N. W.; and on the side of this land most distant from the continent is situated Nootka Sound. The most peculiar circumstance of this navigation is the extreme depth of water, when contrasted with the narrowness of the channels. The vessels were sometimes drifted about by the currents during the whole of a night, close to the rocks, without knowing how to help themselves, on account of the darkness, and the depth being much too great to afford them anchorage.

In the course of this survey, the voyagers had frequent communications with the natives, whom they met sometimes in canoes and sometimes at their villages. In their transactions with Europeans, they are described as "well versed in the principles of trade, which they carried on in a very fair and honourable manner." In other respects they were less honest. At one village 200 sea otter skins were purchased of them by the crews of the vessels in the course of a day; and they had many more to sell in the same place, as also skins of bears, deer, and other animals. One party of Indians whom they met had the skin of a young lioness; and these spoke a language different from that used in Nootka Sound. Venison was sometimes brought for sale; and a piece of copper, not more than a foot square, purchased one whole deer and part of another. Among other articles of traffic, two children, six or seven years of age, were offered for sale. The commodities most prized by the natives were fire-arms, copper, and great coats. Beads and trinkets they would only receive as presents, and not as articles of exchange. Many of them were possessed of fire-arms. In one part it is related, that after a chief had received some presents, "he, with most of his companions, returned to the shore; and, on landing, fired several muskets, to shew, in all probability, with what dexterity they could use these weapons, to which they seemed as familiarized as if they had been accustomed to fire-arms from their earliest infancy."

The dresses of these people, besides skins, are a kind of woollen garments; the materials composing which are explained in the following extract:

"The dogs belonging to this tribe of Indians were numerous, and much resembled those of Pomerania, though,

though, in general, somewhat larger. They were all shorn as close to the skin as sheep are in England; and so compact were their fleeces, that large portions could be lifted up by a corner without causing any separation. They were composed of a mixture of a coarse kind of wool, with very fine long hair, capable of being spun into yarn. This gave Captain Vancouver reason to believe, that their woollen clothing might in part be composed of this material mixed with a finer kind of wool from some other animal, as their garments were all too fine to be manufactured from the coarse coating of the dog alone."

Of other animals alive, deer only were seen in any abundance by our people.

The number of inhabitants computed to be in the largest of the villages or towns that were discovered, did not exceed 600. Captain Vancouver conjectured the small pox to be a disease common and very fatal among them. Many were much marked; and most of these had lost their right eye. Their method of disposing of their dead is very singular.

"Baskets were found suspended on high trees, each containing the skeleton of a young child; in some of which were also small square boxes filled with a kind of white paste, resembling (says our author) such as I had seen the natives eat, supposed to be made of the saranne root; some of these boxes were quite full, others were nearly empty, eaten probably by the mice, squirrels, or birds. On the next low point south of our encampment, where the gunners were airing the powder, they met with several holes in which human bodies were interred, slightly covered over, and in different states of decay, some appearing to have been very recently deposited. About half a mile to the northward of our tents, where the land is nearly level with high water mark, a few paces within the skirting of the wood, a canoe was found suspended between two trees, in which were three human skeletons.

"On each point of the harbour, which, in honour of a particular friend, I called *Penn's Cove*, was a deserted village; in one of which were found several sepulchres, formed exactly like a centry box. Some of them were open, and contained the skeletons of many young children tied up in baskets: the smaller bones of adults were likewise noticed, but not one of the limb bones could here be found; which gave rise to an opinion, that these, by the living inhabitants of the neighbourhood, were appropriated to useful purposes; such as pointing their arrows, spears, or other weapons."

However honourably these people have been represented in their conduct as traders, it appeared on several occasions that it was unsafe to depend on their goodwill alone: and some instances occurred, of their making every preparation for an attack, from which they desisted only on being doubtful of the event; yet immediately on relinquishing their purpose, they would come with the greatest confidence to trade, appearing perfectly regardless of what had before been in agitation. The boats, as already noticed, were frequently at a great distance from the ships; and on such occasions, when large parties of Indians have first seen them, they generally held long conferences among themselves before they approached the boats; probably for the purpose of determining the mode of conduct which they judged it most prudent to observe. Captain Vancouver places the entrance of the strait of Juan de Fuca in 48° 20′ N. Lat. and 124° W. Long.

Jugglers.

JUGGLERS are a kind of people whose profession has not been often deemed either respectable or useful. Professor Beckmann, however, has undertaken their defence; and in a long and learned chapter in the third volume of his *History of Inventions*, pleads the cause of the practisers of legerdemain, rope dancers; persons who place their bodies in positions apparently dangerous; and of those who exhibit feats of uncommon strength. All these men he classes under the general denomination of *Jugglers*; and taking it for granted (surely upon no good grounds) that every useful employment is full, he contends, that there would not be room on the earth for all its present inhabitants did not some of them practise the arts of *Juggling*.

"These arts (says he) are indeed not unprofitable, for they afford a comfortable subsistence to those who practise them; but their gain is acquired by too little labour to be hoarded up; and, in general, these roving people spend on the spot the fruits of their ingenuity; which is an additional reason why their stay in a place should be encouraged. But farther, it often happens, that what ignorant persons first employ, merely as a show, for amusement or deception, is afterwards ennobled by being applied to a more important purpose. The machine with which a Savoyard, by means of shadows, amused children and the populace, was by Liberkühn converted into a solar microscope; and, to give one example more, the art of making ice in summer, or in a heated oven, enables guests, much to the credit of their hostess, to cool the most expensive dishes. The Indian discovers precious stones, and the European, by polishing, gives them a lustre.

"But, if the arts of juggling served no other end than to amuse the most ignorant of our citizens, it is proper that they should be encouraged for the sake of those who cannot enjoy the more expensive deceptions of an opera. They answer other purposes, however, than that of merely amusing: they convey instruction in the most acceptable manner, and serve as an agreeable antidote to superstition, and to that popular belief in miracles, exorcism, conjuration, sorcery, and witchcraft, from which our ancestors suffered so severely."

Surely this reasoning, as well as the cause in which it is brought forward, is unworthy of the learning of Beckmann. It is indeed true, that jugglers spend their money freely, and that their arts afford them the means of subsistence; but it is very seldom, as our author must know, that they subsist either comfortably or innocently. Is it innocent to entice the ignorant and labouring poor, by useless deceptions, to part with their hard earned pittance to idle vagabonds? or is the life of those vagabonds comfortable, when it is passed amid scenes of the most grovelling dissipation? Jugglers spend indeed their money, for the most part, on the spot where it is gained; but they spend it in drunkenness, and other seducing vices, which corrupt their own morals and the morals of all with whom they associate; and therefore their stay in a place should certainly *not* be encouraged. Could it be proved that the solar microscope would never have been invented, had not a Savoyard juggler contrived a similar machine to amuse children and the rabble, some stress might be laid on the service which such wretches have

Jugglers. have rendered to science: but where is the man that will suppose the philosophy of Bacon and Newton to rest upon the arts of jug[illegible]? or who considers the refinements of science as of equal value with the morals of the people? There is, at the moment in which this article is drawing up, a fellow exhibiting, before the windows of the writer's chamber, the most indecent scenes by means of puppets, and keeping the mob in a constant roar. Is he innocently employed? or will any good man say that there is not room for him in the armies which on the Continent are fighting in the cause of God and humanity?

Our author endeavours to strengthen his reasoning by proving, which he does very completely, the antiquity of juggling. "The deception (says he) of breathing out flames, which at present excites, in a particular manner, the astonishment of the ignorant, is very ancient. When the slaves in Sicily, about a century and a half before our æra, made a formidable insurrection, and avenged themselves in a cruel manner for the severities which they had suffered, there was amongst them a Syrian named Eunus, a man of great craft and courage, who, having passed through many scenes of life, had become acquainted with a variety of arts. He pretended to have immediate communication with the gods; was the oracle and leader of his fellow slaves; and, as is usual on such occasions, confirmed his divine mission by miracles. When, heated by enthusiasm, he was desirous of inspiring his followers with courage, he breathed flames or sparks among them from his mouth while he was addressing them. We are told by historians, that for this purpose he pierced a nut-shell at both ends, and, having filled it with some burning substance, put it into his mouth and breathed through it.

"This deception, at present, is performed much better. The juggler rolls together some flax or hemp, so as to form a ball about the size of a walnut; sets it on fire; and suffers it to burn till it is nearly consumed; he then rolls round it, while burning, some more flax; and by these means the fire may be retained in it for a long time. When he wishes to exhibit, he slips the ball unperceived into his mouth and breathes through it; which again revives the fire, so that a number of weak sparks proceed from it; and the performer sustains no hurt, provided he inspire the air not through the mouth but the nostrils.

"For deceptions with fire the ancients employed also naphtha, a liquid mineral oil, which kindles when it only approaches a flame. (See NAPHTHA, *Encycl.*) Galen informs us, that a person excited great astonishment by extinguishing a candle and again lighting it, without any other process than holding it immediately against a wall or a stone. The whole secret of this consisted in having previously rubbed over the wall or stone with sulphur. But as the author, a few lines before, speaks of a mixture of sulphur and naphtha, we have reason to think that he alludes to the same here. Plutarch relates how Alexander the Great was astonished and delighted with the secret effects of naphtha, which were exhibited to him at Ecbatana. The same author, as well as Pliny, Galen, and others, has already remarked, that the substance with which Medea destroyed Creusa, the daughter of Creon, was nothing else than this fine oil. She sent to the unfortunate princess a dress besmeared with it, which burst into flames as soon as she approached the fire of the altar. The blood of Nessus, in which the dress of Hercules, which took fire likewise, had been dipped, was undoubtedly naphtha also; and this oil must have been always employed when offerings caught fire in an imperceptible manner.

Jugglers Jungle.

"In modern times, persons who could walk over burning coals or red-hot iron, or who could hold red-hot iron in their hands, have often excited wonder. But laying aside the deception sometimes practised on the spectators, the whole of this secret consists in rendering the skin of the soles of the feet and hands so callous and insensible, that the nerves under them are secured from all hurt, in the same manner as by shoes and gloves. Such callosity will be produced if the skin is continually compressed, singed, pricked, or injured in any other manner. Thus do the fingers of the industrious sempstress become horny by being frequently pricked; and the case is the same with the hands of fire-workers, and the feet of those who walk bare footed over scorching sand.

"In the month of September 1765, when I visited (says our author) the copper-works at Awestad, [illegible] the workmen, for a little drink money, took [illegible] the melted copper in his hand, and after shewing [illegible] us, threw it against a wall. He then squeezed the fingers of his horny hand close to each other, [illegible] it a [illegible] minutes under his arm-pit, to make it sweat, as he said; and, taking it again out, drew it over a ladle filled with melted copper, some of which he skimmed off, and moved his hand backwards and forwards very quickly, by way of ostentation. While I was viewing this performance, I remarked a smell like that of singed horn or leather, though his hand was not burnt. It is highly probable, that people who hold in their hands red hot iron, or who walk upon it, as I saw done at [illegible]terdam, but at a distance, make their skin callous before, in the like manner. This may be accomplished by frequently moistening it with spirit of vitriol; according to some the juice of certain plants will produce the same effect; and we are assured by others, that the skin must be very frequently rubbed, for a long time, with oil, by which means, indeed, leather also will become horny *."

Our author then proves, in a very learned manner, that all these tricks were of high antiquity; that the Hirpi, who lived near Rome, jumped through burning coals; that women were accustomed to walk over burning coals at Castabala in Cappadocia, near the temple dedicated to Diana; that the exhibition of balls and cups (see LEGERDEMAIN, *Encycl.*) is often mentioned in the works of the ancients; that in the third century, one Firmus or Firmius, who endeavoured to make himself emperor in Egypt, suffered a smith to forge iron on an anvil placed on his breast; that rope-dancers with balancing poles are mentioned by Petronius and others; and that the various feats of horsemanship exhibited in our circuses passed, in the thirteenth century, from Egypt to the Byzantine court, and thence over all Europe.

JUNGLE, in Bengal, waste land, or land covered with wood and brambles.

K.

Kaarta.

KAARTA, a kingdom in Africa, through which Mr Park passed in his route from the Gambia to the Niger. He describes the country as consisting either of sandy plains or rocky hills; but, from his account, the level part seems to be the most extensive. The natives are negroes, of whom many, though converted to the Mahomedan faith, or rather to the ceremonial part of the Mahomedan religion, retain all their ancient superstitions, and even drink strong liquors. They are called Johers or Jowers, and in Kaarta form a very numerous and powerful tribe. One of these men undertook to conduct our author to Kemmoo, the capital of the kingdom, and alarmed him not a little by his superstitious ceremonies.

"We had no sooner (says Mr Park) got into a dark and lonely part of the first wood, than he made a sign for us to stop, and taking hold of a hollow piece of bamboo, that hung as an amulet round his neck, whistled very loud, three times. I confess I was somewhat startled, thinking it was a signal for some of his companions to come and attack us; but he assured me that it was done merely with a view to ascertain what success we were likely to meet with on our present journey. He then dismounted, laid his spear across the road, and having said a number of short prayers, concluded with three loud whistles; after which he listened for some time, as if in expectation of an answer, and receiving none, told us we might proceed without fear, for there was no danger."

White men were strangers in the kingdom of Kaarta; and the appearance of our author had on some of the natives the effect which ignorant people, in this country, attribute to ghosts. "I had wandered (says he) a little from my people, and being uncertain whether they were before or behind me, I hastened to a rising ground to look about me. As I was proceeding towards this eminence, two negro horsemen, armed with muskets, came galloping from among the bushes: on seeing them I made a full stop; the horsemen did the same, and all three of us seemed equally surprised and confounded at this interview. As I approached them their fears increased, and one of them, after casting upon me a look of horror, rode off at full speed; the other, in a panic of fear, put his hand over his eyes, and continued muttering prayers until his horse, seemingly without the rider's knowledge, conveyed him slowly after his companion. About a mile to the westward, they fell in with my attendants, to whom they related a frightful story: it seems their fears had dressed me in the flowing robes of a tremendous spirit; and one of them affirmed, that when I made my appearance, a cold blast of wind came pouring down upon him from the sky like so much cold water."

At Kemmoo our traveller was graciously received by the king; who honestly told him, however, that he could not protect him, being then engaged in war with the king of BAMBARRA (see SEGO in this *Supplement*); but he gave him a guard to JARRA, the frontier town of the neighbouring kingdom of Ludamar. The origin and issue of this war between Kaarta and Bambarra, of which Mr Park gives a full account, shews the folly of attempting to liberate the negroes from slavery till civilization and Christianity be introduced into Africa. Major Rennel places Kemmoo, the capital of Kaarta, in 14° 15′ N. Lat. and 7° 20′ W. Lon.

Kabobiquas.

KABOBIQUAS, a nation in south Africa, who had never seen a white man till 1785, that they were visited by M. Vaillant. Intimation had been given of his approach by some of the tribes through whose country he had previously passed; and every thing that had been said of his colour, his fusees, and his equipage, bore the character of the most enthusiastic exaggeration. The curiosity of the people was wound up to the highest pitch; and as soon as they saw his company at a distance, the whole horde quitted the kraal, and ran with eagerness to meet him. Not being able to believe their eyes in regard to what they saw, they endeavoured to obtain more satisfaction by touching him. They felt his hair, hands, and almost every part of his body. His beard, above all, astonished them to an inconceivable degree. More than thirty persons came in succession, and half unbuttoned his clothes. They all imagined him to be a hairy animal; and supposed, without doubt, that his body was covered with hair as long as that on his chin; but finding this not to be the case, they were astonished, and confessed, with the openness of savages, that they had never seen the like in any man of their country. The little children, terrified at his appearance, hid themselves behind their mothers. When he attempted to lay hold of any of them, in order to caress them, they sent forth loud cries, as a child would do in Europe who should see a negro for the first time.

The grown up people, however, were soon reconciled to his appearance, and even the children were bribed by small bits of sugar candy. The chief of the horde showed him every mark of attachment. He was a man advanced in life, and of a majestic figure. He wore a long mantle, which hung from his shoulders to the ground, and which, formed of four jackal skins joined together, was bordered at the sides with that of a hyæna. His left hand wanted two joints of the little finger, which, he said, were amputated in his infancy to cure him of a severe illness.

This custom of savages, who, to relieve a man from pain, add new sufferings to his evils, affords a vast field for reflection. Mr Paterson, another African traveller, tells us, that he observed instances of the same practice among a horde at the mouth of Orange-river; which is not improbable. However absurd a custom may be, savage tribes, when they are neighbours, may borrow it from each other; but that it should be common among the islanders of the South Sea, who, since their country was first inhabited, had never seen strangers before Cook and Bougainville, is truly astonishing. Our author was very desirous of interrogating minutely the people of the horde on this subject. He wished also to propose some questions to them respecting other customs which appeared singular; but difficulties increased the more he advanced into the country. The Kabobiquas spoke a particular language, and this dialect, though

 accompanied

Kabobiquas accompanied with the clapping noise of the Hottentots, was understood only by the Koraquas, who, on account of their vicinity, kept up some intercourse with them. The case was the same with the language of the Koraquas, in regard to their neighbours the Nimiquas; and nothing reached our author's ear till it had passed through four different mouths. The consequence was, that when he asked any thing, the answer had frequently no relation to the question; and for this inconveniency no remedy could be found.

The same desire for trinkets to ornament their dress prevailed among the Kabobiquas as among the other hordes which Vaillant had visited; and in one day he purchased twenty oxen for things of that kind of no value. The chief, however, had set his affections on a razor; and just when our author and he were treating about it, a shot was fired near them, which was instantly followed by the most frightful cries. "Rushing instantly from my tent (says M. Vaillant) to enquire what was the cause of this noise, I saw a Kabobiqua flying as fast as he could from one of my hunters, while, at the distance of a hundred paces farther, three men were making the most lamentable clamour, and near them was a young girl lying on the ground. I made a signal to my hunter to approach me; but the report of the shot, and the howling of the three men, had already spread alarm throughout the horde. Some cried out treachery; others ran to their arms; and I now imagined that I was about to be massacred, with my whole company, and that I should be obliged to arm them in my defence. My situation was the more critical, as neither I, nor any person in the kraal, knew what was the cause of this confusion; and if I had known, how could I have explained it?

"Under this embarrassment, I took the chief by the hand, and advanced with him towards the horde. Fear was painted in his countenance; tears began to drop from his eyes; and he spoke to me with great vivacity. He imagined, no doubt, that he was betrayed. He complained to me, and accused my people of perfidy; yet he readily followed me.

"As I was without arms, and presented myself with the chief, I was received with confidence, and my appearance seemed, in some measure, to calm their perturbation. My people, who had seen me direct my course towards the kraal, hastened thither after me, to protect me; and their number overawed the multitude. At length the whole mystery was cleared up, and we learned what had occasioned the tumult.

"A Kabobiqua having met one of my hunters, who was returning with his fusee, wished to examine it, and begged him to shew it to him. In handling it, however, he accidentally touched the trigger; it instantly went off; and the savage, frightened by the unexpected explosion, threw down the fusee, and ran away as fast as he could.

"At that time, three men of the horde and a young girl happened unluckily to be standing, at the distance of a hundred paces, in the direction of the piece. The latter received a single grain of shot in the cheek; and the others a few grains in the legs and thighs. The author of the misfortune confirmed this explanation; tranquillity was soon restored; the savages deposited their arms; and I was surrounded only by friends as before.

"Nothing remained but to enquire into the state of the wounded, and to give them every assistance in my power. Without loss of time, therefore, I repaired, still accompanied by the chief, to the place where they were. By the way we met the young girl, who was returning from the kraal, bathed in tears. The cause of her uneasiness was a grain of lead, which had, however, penetrated so little, that I forced it out by only pressing the part with my fingers. With regard to the three men, they lay rolling on the ground, howling in a most frightful manner, and exhibiting every symptom of despair.

"I was astonished at their consternation, and could not conceive how men inured to sufferings should be so much affected by a few small punctures, the pain of which could have scarcely drawn tears from an infant. They at length told me the cause of their wailings. These savages, accustomed to poison their arrows, imagined that I had in like manner poisoned the lead with which they were wounded. They had, therefore, given themselves up as lost, and expected in a few moments to expire."

It was with great difficulty that our author could convince them that they had nothing to fear. He shewed them in the flesh of his own leg a dozen of shots of lead; but they were not satisfied till one of the most intelligent of his Hottentots, taking from his shot bag a few grains of lead, and shewing them to the three men, immediately swallowed them. This conclusive argument produced the desired effect. The cries of the wounded men instantly ceased; serenity again appeared in their faces; and their wounds were no more mentioned.

The Kabobiquas have neither the flat nose nor plump cheeks of the Hottentots. Their skin also has not that bastard colour, which, being neither black nor white, renders them odious to both races; nor do they besmear their bodies with those disgusting fat substances, on account of which one cannot approach them without being bedaubed with their filth, or acquiring an offensive smell. In stature they are as tall as the Caffres, and their colour is equally black. Their hair, which is exceedingly short, and much curled, is ornamented with small copper buttons, arranged with great art and symmetry. Instead of that apron made of a jackal's skin, employed by the Hottentot to cover what modesty bids him conceal, the Kabobiquas use a round piece of leather, the edge of which is ornamented with a small indented circle of copper, and which is divided into different compartments by rows of glass beads of various colours, all proceeding from the centre, and diverging towards the circumference, like the rays in our images of the sun.

This kind of veil is made fast to the groin by means of a girdle; but as it is only four inches in diameter, as it is deranged by the smallest movement, and as they give themselves little uneasiness respecting such accidents, it is very ill suited to the purpose for which it is applied. During the great heats, this small and almost useless apron is the only covering on their bodies. Its being so readily displaced, enabled our author to ascertain that they do not practice circumcision; but it seemed to show also, that, in regard to modesty, their ideas are very different from ours.

Though they go thus almost entirely naked, their manners, instead of being licentious, are remarkably chaste.

Kainsi, Kamtschatka.

like theirs, is rounded at the end; and as it is always accustomed, both in leaping and walking, to tread with the point of the hoof, without resting at all on the heel, it leaves a print distinguishable from that of any other antelope in Africa. Its flesh is exquisitely flavoured, and much sought after, particularly by the hunters.

The chace of the kainsi is very amusing. It is true, it is scarcely possible to hunt it down with dogs, as it soon escapes them by means of its inconceivable agility, and gets out of their reach on the point of some detached rock, where it will remain whole hours safe from all pursuit, and suspended, as it were, above the abyss. But in this situation it is excellently placed for the arrow or the ball of the huntsman; who is commonly certain of shooting it at pleasure, though he is not always able to come at it when killed. We shall give our author's account of a chace of the kainsi in his own words.

"I was hunting (says he) one of these animals, when, from the nature of the place, it found itself so pressed by my dogs, as to be on the point of being run down and taken. There were apparently no means of escape; since before it was a vast perpendicular rock, by which its course was necessarily stopped. In this wall, however, which appeared to me perfectly smooth, was a little ridge, projecting at most not above *two inches*, which the kainsi quickly perceived, and, leaping upon it, to my great astonishment kept itself *firm* (A). I imagined, that at any rate it must soon tumble down; and my dogs, too, so fully expected it, that they ran to the bottom of the rock, to be ready to catch it when it fell. To hasten its fall, I endeavoured to harass it, and make it lose its equilibrium; and for this purpose I pelted it with stones. All at once, as if guessing my design, it collected its whole strength, bounded over my head, and, falling a few paces from me, darted away with the utmost speed. Notwithstanding the rapidity of its flight, it would have been easy for me to have shot it; but its leap had so surprised and amused me, that I gave it its life." This was generous, if the story be true.

KAMTSCHATKA is inhabited by a people, who are represented in the *Encyclopædia* as possessing almost every quality that can disgrace human nature. We think it incumbent upon us to acknowledge, in this place, that a much more favourable picture of them is drawn by La Perouse who visited Kamtschatka in September 1787. The Russian governor made the commodore and his officers remark the promising appearance of several small fields of potatoes, of which the seed had been brought from Irkoutsk a few years before; and purposed to adopt mild, though infallible means, of making farmers of the Russians, Cossacks, and Kamtschadales. The small-pox in 1769 swept away three-fourths of the individuals of the latter nation, which is now reduced to less than four thousand persons, scattered over the whole of the peninsula; and which will speedily disappear altogether, by means of the continual mixture of the Russians and Kamtschadales, who frequently intermarry. A mongrel race, more laborious than the Russians, who are only fit for soldiers, and much stronger, and of a form less disgraceful to the hand of nature, than the Kamtschadales, will spring from these marriages, and succeed the ancient inhabitants. The natives have already abandoned the *yourts*, in which they used to burrow like badgers during the whole of the winter, and where they breathed an air so foul as to occasion a number of disorders. The most opulent among them now build *isbas*, or wooden houses, in the manner of the Russians They are precisely of the same form as the cottages of our peasants; are divided into three little rooms; and are warmed by a brick stove, that keeps up a degree of heat (B) insupportable to persons unaccustomed to it. The rest pass the winter, as well as the summer, in *balagans*, which are a kind of wooden pigeon-houses, covered with thatch, and placed upon the top of posts twelve or thirteen feet high, to which the women as well as the men climb by means of ladders that afford a footing very insecure. But these latter buildings will soon disappear; for the Kamtschadales are of an imitative genius, and adopt almost all the customs of their conquerors. Already the women wear their hair, and are almost entirely dressed, in the manner of the Russians, whose language prevails in all the *ostrogs*; a fortunate circumstance, since each Kamtschadalian village spoke a different jargon, the inhabitants of one hamlet not understanding that of the next. It may be said in praise of the Russians, that though they have established a despotic government in this rude climate, it is tempered by a mildness and equity that render its inconveniences unfelt. They have no reproaches of atrocity to make themselves, like the Spaniards in Mexico and Peru. The taxes they levy on the Kamtschadales are so light, that they can only be considered as a mark of gratitude towards the sovereign, the produce of half a day's hunting acquitting the imposts of a year. It is surprising to see in cottages, to all appearance more miserable than those of the most wretched hamlets in our mountainous provinces, a quantity of species in circulation, which appears the more considerable, because it exists among so small a number of inhabitants. They consume so few commodities of Russia and China, that the balance of trade is entirely in their favour, and that it is absolutely cessary to pay them the difference in rubles. Furs at Kamtschatka are at a much higher price than at Canton; which proves, that as yet the market of Kiatcha has not felt the advantageous effect of the new channel opened in China.

Our author compares Kamtschatka, with respect to climate and soil, to the coast of Labrador in the vicinity of the Straits of Belle-Isle; but the men, like the animals, are there very different. The Kamtschadales appeared to him the same people as those of the bay of Castries, upon the coast of Tartary. Their mildness and their probity are the same, and their persons are very little different. They ought then no more to be compared to the Esquimaux Indians, than the sables of Kamtschatka to the martins of Canada.

The Greek religion has been established among the Kamtschadales without persecution or violence, and with extraordinary facility. The vicar of Paratounka is the son of a Kamtschadale and of a Russian woman. He delivers his prayers and catechism with a tone of feeling very

(A) This we think incredible.
(B) Not less than thirty degrees of Reaumur's thermometer.

very much to the taſte of the aborigines, who reward his cares with offerings and alms, but pay no tythes. The canons of the Greek church permitting prieſts to marry, we may conclude that the morals of the country clergymen are ſo much the better. "I believe them, however (ſays Perouſe), to be very ignorant; and do not ſuppoſe, that for a long time to come they will ſtand in need of greater knowledge. The daughter, the wife, and the ſiſter of the vicar, were the beſt dancers of all the women, and appeared to enjoy the beſt ſtate of health. The worthy prieſt knew that we were good Catholics, which procured us an ample aſperſion of holy water; and he alſo made us kiſs the croſs that was carried by his clerk: theſe ceremonies were performed in the midſt of the village. His parſonage-houſe was a tent, and his altar in the open air; but his uſual abode is Paratounka, and he only came to St Peter and St Paul's to pay us a viſit."

The people of Kamtſchatka have inured themſelves to the extremes of heat and cold. It is well known, that their cuſtom in Europe, as well as in Aſia, is to go into vapour baths, come out covered with perſpiration, and immediately roll themſelves in the ſnow. The *oſtrog* of St Peter had two of theſe public baths, into which our author went before the fires were lighted. They conſiſt of a very low room, in the middle of which is an oven conſtructed of ſtones, without cement, and heated like thoſe intended to bake bread. Its arched roof is ſurrounded by ſeats one above another, like an amphitheatre, for thoſe who wiſh to bathe, ſo that the heat is greater or leſs according as the perſon is placed upon a higher or lower bench. Water thrown upon the top of the roof, when heated red-hot by the fire underneath, is converted inſtantly into vapour, and excites the moſt profuſe perſpiration. The Kamtſchadales have borrowed this cuſtom, as well as many others, from their conquerors; and ere long the primitive character that diſtinguiſhed them ſo ſtrongly from the Ruſſians will be entirely effaced.

Our author deſcribes the bay of Avatſcha as the fineſt, the moſt convenient, and the ſafeſt, that is to be met with in any part of the world. The entrance is narrow, and ſhips would be forced to paſs under the guns of the forts that might be eaſily erected. The bottom is mud, and excellent holding ground. Two vaſt harbours, one on the eaſtern ſide, the other on the weſtern, are capable of containing all the ſhips of the French and Engliſh navy. The rivers of Avatſcha and Paratounka fall into this bay, but they are choaked up with ſand-banks, and can only be entered at the time of high water. The village of St Peter and St Paul is ſituated upon a tongue of land, which, like a jetty made by human art, forms behind the village a little port, ſhut in like an amphitheatre, in which three or four veſſels might lie up for the winter. The entrance of this ſort of baſon is more than twenty-five toiſes wide; and nature can afford nothing more ſafe or commodious. On its ſhore the governor propoſed to lay down the plan of a city, which ſome time or other will be the capital of Kamtſchatka, and perhaps the centre of an extenſive trade with China, Japan, the Phillippines, and America. A vaſt pond of freſh water is ſituated northward of the ſite of this projected city; and at only three hundred toiſes diſtance run a number of ſtreamlets, the eaſy union of which would give the ground all the advantages neceſſary to a great eſtabliſhment. Of theſe advantages Mr Kaſloff underſtood the value; "but firſt (ſaid he a thouſand times over) we muſt have bread and hands, and our ſtock of both of them is very ſmall." He had, however, given orders, which announced a ſpeedy union of the other *oſtrogs* to that of St Peter and St Paul, where it was his intention immediately to build a church. By obſervation, St Peter and St Paul was found to be in 53° 1′ N. Lat. and 156° 30′ E. Long. from Paris.

KANEM, is the name given by Edriſi to the kingdom of Bornou in Africa, of which the reader will find ſome account in the *Encyclopædia Britannica*. In ſome particulars, however, that account is incorrect. The kingdom of Bornou or Kanem muſt extend farther eaſt and farther north than it is there ſaid to do; for according to the lateſt and beſt accounts, its capital ſtands in Lat. 24° 32′ Long. 22° 57′. The empire is ſaid to be very extenſive; and if it be true, as we learn from the proceedings of the African Aſſociation, that its ſovereign is more powerful than the Emperor of Morocco, the people cannot be ſuch abſolute brutes, as we have repreſented them in the article referred to; for the ſovereign of brutes would have no power. The truth, however is, that very little is yet known in Europe of Bornou or its inhabitants.

KANT (*Immanuel*), Royal Profeſſor of Morals and Metaphyſics in the Univerſity of Königſberg, is conſidered by his admirers as the greateſt philoſopher that Germany ever produced. Were we to form an eſtimate of his merits from the different views that have been given in Engliſh of his celebrated ſyſtem, we certainly ſhould not conſider him as entitled to that character; for thoſe views are obſcured by new and uncouth terms, and are altogether wrapt up in a ſtyle which approaches nearer to jargon than to the luminous compoſition of a man who thinks with clearneſs and preciſion. We readily admit, that it is very difficult to tranſlate a novel ſyſtem of metaphyſics from one language into another; for the tranſlator, to perform his taſk properly, muſt be not only a complete maſter of both languages, but alſo a profound metaphyſician; and not one of the tranſlators or abridgers of the works of Kant into our language appears to us poſſeſſed of both theſe qualities. Deſpairing, from our ſcanty knowledge of the German language, of performing ourſelves what ſo many others have failed to perform, we have applied for aſſiſtance to an illuſtrious Frenchman, who has reſided many years in Germany, who is maſter of both languages, who is a profound metaphyſician, and whoſe name, were we at liberty to publiſh it, would reflect luſtre upon our Work. From him we have reaſon to expect a clear and comprehenſive view of the *Critical* PHILOSOPHY, as Kant terms his ſyſtem; but ſhould we be diſappointed of our expectation, we ſhall, under that title, lay before our readers a *ſpecimen* of the ſyſtem from the different views of it which have been publiſhed in our own tongue.

KANTUFFA, a ſpecies of thorn peculiar to Abyſſinia, is thus deſcribed by Mr Bruce: The branches ſtand two and two upon the ſtalk; the leaves are diſpoſed two and two likewiſe, without any ſingle one at the point, whereas the branches bearing the leaves part from the ſtalk: at the immediate joining of them are two thick thorns placed perpendicular and parallel alternately;

Kantuffa, Kaffon.

ly; but there are alfo fingle ones diftributed in all the interftices throughout the branch.

The male plant has a one-leaved perianthium, divided into five fegments, and this falls off with the flower. The flower is compofed of five petals, in the middle of which rife ten ftamina or filaments, the outer row fhorter than thofe of the middle, with [illegible] ftigmata, having yellow farina upon them. The flowers grow in a branch, generally between three and four inches long, in a conical difpofition, that is, broader at the bafe than the point. The infide of the leaves are a vivid green, in the outfide much lighter. It grows in form of a bufh, with a multitude of fmall branches rifing immediately from the ground, and is generally feven or eight feet high. Our author faw it when in flower only, never when bearing fruit. It has a very ftrong fmell, refembling that of the fmall fcented flower called mignionet, fown in vafes and boxes in windows, or rooms, where flowers are kept.

Our author reprefents the kantuffa as fo very troublefome, that it renders travelling through fome places of Abyffinia almoft impoffible. The foldier fcreens himfelf from it by a goat's, a leopard's, or a lion's fkin thrown over his fhoulder, of which it has no hold. As his head is bare, he always cuts his hair fhort before he goes to battle, left his enemy fhould take advantage of it; but the women, wearing their hair long, and the great men, whether in the army or travelling in peace, being always clothed, it never fails to incommode them, whatever fpecies of raiment they wear. If their cloak is fine muflin, the leaft motion againft it puts it all in rags; but if it is a thick, foft cloth, as thofe are with which men of rank generally travel, it buries its thorns, great and fmall, fo deep in it, that the wearer muft either difmount and appear naked, which to principal people is a great difgrace, or elfe much time will be fpent before he can difengage himfelf from its thorns. In the time when one is thus employed, it rarely fails to lay hold of you by the hair, and that again brings on another operation, full as laborious, but much more painful, than the other. A proclamation is therefore iffued, every year immediately before the king commences any march, in thefe words; "Cut down the kantuffa in the four quarters of the world; for I do not know where I am going." The wild animals, both birds and beafts, efpecially the Guinea fowl, know how well it is qualified to protect them. In this fhelter, the hunter in vain could endeavour to moleft them, were it not for a hard haired dog, or terrier of the fmalleft fize, who being defended from the thorns by the roughnefs of his coat, goes into the cover, and brings them and the partridges alive one by one to his mafter.

KASSON, a populous kingdom in North Africa, of which the capital *Kooniakary* is placed by Major Rennel in 14° 33′ N. Lat. and 8° 43′ W. Lon. The king who reigned when Mr Park was in the country was extremely kind to our traveller, though his fon plundered him unmercifully, like other rapacious chiefs of that favage country. From the top of a high hill, at fome diftance from the capital, "I had (fays Mr Park) a moft enchanting profpect of the country. The number of towns and villages, and the extenfive cultivation around them, furpaffed every thing I had yet feen in Africa. A grofs calculation may be formed of the number of inhabitants in this delightful plain, by confidering, that the king of Kaffon can raife four thoufand fighting men by the found of his war drum."

At Teefee, a large unwalled town, where our author refided for fome days, he had an opportunity of obferving the cuftoms of the inhabitants, who confifted partly of Pagans and partly of Bufhreens, *i. e.* of negroes converted to Mahomedanifm. Though thefe people poffefs both cattle and corn in abundance, rats, moles, fquirrels, fnakes, locufts, &c. are eaten without fcruple by the higheft and loweft. Another cuftom, ftill more extraordinary, is, that no woman is allowed *to eat an egg.* This prohibition, whether arifing from ancient fuperftition, or from the craftinefs of fome old Bufhreen who loved eggs himfelf, is rigidly adhered to; and nothing will more affront a woman of Teefee than to offer her an egg. The cuftom is the more fingular, as the men eat eggs without fcruple in the prefence of their wives, and Mr Park never obferved the fame prohibition in any other of the Mandingo countries.

Our author was prefent at a palaver held by the governor of Teefee on a very extraordinary occafion; of which we fhall give his account at full length, becaufe it fhows how free men are reduced to flavery in North Africa. "The cafe was this. A young man, a Kafir, of confiderable affluence, who had recently married a young and handfome wife, applied to a very devout Bufhreen, or Muffulman prieft, of his acquaintance, to procure him faphies for his protection during the approaching war. The Bufhreen complied with the requeft; and in order, as he pretended, to render the faphies more efficacious, enjoined the young man to avoid any nuptial intercourfe with his bride for the fpace of fix weeks. Severe as the injunction was, the Kafir ftrictly obeyed; and without telling his wife the real caufe, abfented himfelf from her company. In the mean time it began to be whifpered at Teefee, that the Bufhreen, who always performed his evening devotions at the door of the Kafir's hut, was more intimate with the young wife than he ought to be. At firft, the good hufband was unwilling to fufpect the honour of his fanctified friend, and one whole month elapfed before any jealoufy rofe in his mind: but hearing the charge repeated, he at laft interrogated his wife on the fubject, who frankly confeffed that the Bufhreen had feduced her. Hereupon the Kafir put her into confinement, and called a palaver upon the Bufhreen's conduct. The fact was clearly proved againft him; and he was fentenced to be fold into flavery, or to find two flaves for his redemption, according to the pleafure of the complainant. The injured hufband, however, was unwilling to proceed againft his friend to fuch extremity, and defired rather to have him publicly flogged before the governor's gate. This was agreed to, and the fentence was immediately executed. The culprit was tied by the hands to a ftrong ftake; and a long black rod being brought forth, the executioner, after flourifhing it round his head for fome time, applied it with fuch force and dexterity to the Bufhreen's back, as to make him roar until the woods refounded with his fcreams. The furrounding multitude, by their hooting and laughing, manifefted how much they enjoyed the punifhment of this old gallant; and it is worthy of remark, that the number of ftripes was precifely the fame as are enjoined by the Mofaic law, *forty, fave one.*"

The method of converting the negro nations to the religion

Kasson. religion of the Arabian Impostor is a very singular one; and Mr Park saw the whole people of Teesee converted in an instant. During his residence in that town an embassy of ten people belonging to Almami Abdulkader, king of Foota Torra, a country to the west of Bondou, arrived at Teesee; and desiring Tiggity Sego the governor to call an assembly of the inhabitants, announced publicly their king's determination, to this effect: "That unless all the people of Kasson would embrace the Mahomedan religion, and evince their conversion by saying eleven public prayers, he (the king of Foota Torra) could not possibly stand neuter in the present contest, but would certainly join his arms to those of Kajaaga." A message of this nature, from so powerful a prince, could not fail to create great alarm; and the inhabitants of Teesee, after a long consultation, agreed to conform to his good pleasure, humiliating as it was to them. Accordingly, one and all publicly offered up eleven prayers, which were considered a sufficient testimony of their having renounced Paganism, and embraced the doctrines of the Prophet.

Our author relates a story, which we cannot refuse ourselves the pleasure of inserting, because it exhibits a very pleasing picture of the affection and gratitude of the Pagan negroes. In his train was a blacksmith, who had lived some years on the Gambia, and who now returned to his own country *Kasson*. "Soon after we came in sight of Jumbo, his native town (says Mr Park), his brother, who had by some means been apprised of his coming, came out to meet him, accompanied by a singing man; he brought a horse for the blacksmith, that he might enter his native town in a dignified manner; and he desired each of us to put a good charge of powder into our guns. The singing man now led the way, followed by the two brothers; and we were presently joined by a number of people from the town, all of whom demonstrated great joy at seeing their old acquaintance the blacksmith, by the most extravagant jumping and singing. On entering the town, the singing man began an extempore song in praise of the blacksmith, extolling his courage in having overcome so many difficulties; and concluding with a strict injunction to his friends to dress him plenty of victuals.

"When we arrived at the blacksmith's place of residence, we dismounted and fired our muskets. The meeting between him and his relations was very tender; for these rude children of nature, free from restraint, display their emotions in the strongest and most expressive manner. Amidst these transports, the blacksmith's aged mother was led forth, leaning upon a staff. Every one made way for her; and she stretched out her hand to bid her son welcome. Being totally blind, she stroked his hands, arms, and face, with great care, and seemed highly delighted that her latter days were blessed by his return, and that her ears once more heard the music of his voice. From this interview I was fully convinced, that whatever difference there is between the Negro and European in the conformation of the nose and the colour of the skin, there is none in the genuine sympathies and characteristic feelings of our common nature.

"During the tumult of these congratulations, I had seated myself apart, by the side of one of the huts, being unwilling to interrupt the flow of filial and parental tenderness; and the attention of the company was so entirely taken up with the blacksmith, that I believe none of his friends had observed me. When all the people present had seated themselves, the blacksmith was desired by his father to give them some account of his adventures; and silence being commanded, he began; and after repeatedly thanking God for the success that had attended him, related every material occurrence that had happened to him from his leaving Kasson to his arrival at the Gambia; his employment and success in those parts; and the dangers he had escaped in returning to his native country. In the latter part of his narration, he had frequently occasion to mention me; and after many strong expressions concerning my kindness to him, he pointed to the place where I sat, and exclaimed, *affille ibi siring*, "see him sitting there." In a moment all eyes were turned upon me; I appeared like a being dropped from the clouds; every one was surprised that they had not observed me before; and a few women and children expressed great uneasiness at being so near a man of such an uncommon appearance. By degrees, however, their apprehensions subsided; and when the blacksmith assured them that I was perfectly inoffensive, and would hurt nobody, some of them ventured so far as to examine the texture of my clothes; but many of them were still very suspicious; and when by accident I happened to move myself, or look at the young children, their mothers would scamper off with them with the greatest precipitation. In a few hours, however, they all became reconciled to me." With these worthy people our author spent the greater part of two days in feasting and merriment; the blacksmith accompanied him to the capital; and declared, that he would not leave him while he resided there. Kasson, Keate.

KEATE (George, Esq; F. R. S.), descended of an ancient and honourable family, was born about the year 1729 or 1730, and received his education at Kingston school, under the Rev. Mr Woodeson. From thence he went to Geneva, where he resided some years, and during his stay there, became acquainted with Voltaire, with whom he continued to correspond many years after he returned to England. After finishing the tour of Europe, he settled as a student in the Inner Temple, was called to the bar, and sometimes attended Westminster Hall; though he did not meet with encouragement enough to induce his perseverance in his profession, nor indeed does it seem probable that he had sufficient application for it. His first literary performance was "Ancient and Modern Rome," a poem, written at Rome in the year 1755, printed in the year 1760, and received with considerable applause. The next year he published "A Short Account of the Ancient History, Present Government, and Laws, of the Republic of Geneva, 8vo." This work was compiled during the author's residence at Geneva; is a very useful one; and is dedicated to Monsieur de Voltaire: to whom he says, "When I reflect, that it was in this Republic, whose government I have attempted to describe, that I was first introduced to your acquaintance; when memory renews the hours of social mirth and refined entertainment which your hospitality and conversation afforded me—I cannot but rejoice in this occasion of expressing my gratitude; proud that, as your friendship distinguished the author of these pages in a foreign country, your name may at home adorn his labour."

It

Keate. It was at one time the intention of Voltaire to translate this account into French, though he afterwards relinquished the design.

The next year, 1762, he produced an "Epistle from Lady Jane Gray to Lord Guildford Dudley:" and in 1763, "The Alps," a poem; the subject of which comprehends all that chain of mountains known under the general name of the Alps, extending from Italy to Germany, and from France to Tyrol, by whatever denomination they are particularly distinguished. Of all the poetical works of Mr Keate, this is intitled to the highest praise for truth of description, elegance of versification, and vigour of fancy.

Continuing to employ the press, in 1764 he published "Netley Abbey," which he afterwards, in 1769, enlarged and reprinted; and, in 1765, produced "The Temple Student, an Epistle to a Friend;" humourously rallying his own want of application to the study of the law, his preference of the belles lettres, and his consequent want of success in his profession. The death of Mrs Cibber in 1766, of whose merits as an actress he entertained the highest opinion, gave occasion for a poem to her memory, which celebrates her excellent performances on the stage, and laments the loss the theatre would sustain by her death.

In February 1769, he married Miss Hudson; and about the same time published "Ferney; an Epistle to M. de Voltaire" In this poem, after praising with energy the various beauties of his friend's poetical works, he introduces the following panegyric on Shakespeare:

Yes! jealous wits may still for empire strive,
Still keep the flames of critic rage alive:
Our Shakespeare yet shall all his rights maintain,
And crown the triumphs of Eliza's reign.
Above controul, above each classic rule,
His tut'ress Nature, and the world his school,
On soaring pinions borne, to him was given
Th' ærial range of Fancy's brightest heav'n;
To bid wrapt thought o'er noblest heights aspire,
And wake each passion with a muse of fire.
Revere his genius. To the dead be just,
And spare the laurels that o'ershade the dust.
Low sleeps the bard, *in cold obstruction laid*,
Nor asks the chaplet from a rival's head.
O'er the drear vault, Ambition's utmost bound,
Unheard shall Fame her airy trumpet sound!
Unheard alike; nor grief nor transport raise
The blast of censure, or the note of praise!
As Raphael's own creation grac'd his hearse,
And sham'd the pomp of ostentatious verse,
Shall Shakespeare's honours by himself be paid,
And Nature perish ere his pictures fade.

This eulogium on Shakespeare, in an an epistle to Voltaire, who had laboured so long and so strenuously to detract from the merit of our immortal bard, shews that Mr Keate had not given up his judgment to the sage of Ferney. How the old and envious sophister would relish his friend's conduct, may be easily conceived. His feelings were certainly very different from those of the mayor and burgesses of Stratford, when, in consequence of this panegyric on their townsman, they complimented Mr Keate with a standish, mounted with silver, made out of the famous Mulberry tree planted by Shakespeare.

In 1773, he published "The Monument in Arcadia," a dramatic poem, built on the picture of Poussin, mentioned by Abbé du Bos in his "Critical Reflections on Poetry and Painting." Keate.

In 1779, Mr Keate produced one of his most successful works, intitled "Sketches from Nature; taken and coloured in a Journey to Margate," 2 vols, 12mo. This performance, allowing it to be, as it really is, an imitation of Sterne's "Sentimental Journey;" yet contains so many pleasing delineations of life, so many strokes of humour, and so much elegance of composition, that few will hesitate to give it the preference to any other of Sterne's imitators.

In 1781, he collected his poetical works in two vols, 12mo, and added several new pieces not before printed. The principal of these was "The Helvetiad," a fragment, written at Geneva in the year 1756. In the preface to this performance he gives the following account of it: "During a long stay I many years since made at Geneva, I visited most of the principal places in Switzerland. The many sublime scenes with which nature hath enriched this romantic country; the tranquillity and content with which every individual enjoys his property; and, above all, that independence of mind which is ever the result of liberty—animated me with such veneration for the first authors of that freedom, whose figures are recorded to posterity either by sculpture or painting in the public parts of the towns thro' those little states, that my enthusiasm betrayed me into a design of writing a poem on this singular revolution; the argument of which I had divided into *ten cantos*, beginning the work with the oppressions of the House of Austria, and closing it with the battle of Mongarten; by which those injured people finally renounced its usurpation, and formed among themselves those various confederacies that ended in the great union and alliance of the present *thirteen cantons*. When I had settled the whole plan of this work, I occasionally, as I found a disposition in myself, took up any part of the poem which at the moment most invited my thoughts: and enjoying at this time such an intercourse with M. de Voltaire as afforded me a constant access to him, I acquainted him with my intention, shewing him the argument I had drawn out for the conduct of the whole design. He kept it a few days; and, in returning it, told me, that he thought the great object of the piece, the episodes connected with the history, together with the scenery of the country, presented subject matter whereon to form a fine poem; "but the time (added he) which such an undertaking will require, I would rather counsel you to employ on subjects that might more engage the public attention; for should you devote yourself to the completion of your present design, the Swiss would be much obliged to you, without being able to read you, and the rest of the world care little about the matter." Feeling the force and justness of the remark; Mr Keate laid aside his plan, and probably never resumed it. In the same year, 1781, he published "An Epistle to Angelica Kauffman."

A few years after, he became engaged in a long and vexatious law-suit, in consequence of the neglect (to say the least of it) of an architect who professed himself to be his friend; the particulars of which it is of no importance to detail. At the conclusion of the business, he shewed that his good humour had not forsaken him:

And

Keate. And in 1787 he gave to the public the principal circumſtances of his caſe in a performance, intitled, "The Diſtreſſed Poet, a ſerio-comic Poem, in three Cantos," 4to, with ſome pleaſantry, and without any acrimony.

His laſt work did infinite honour to his head and his heart, as well as to the liberality of the bookſeller for whom on the title-page it was ſaid to be publiſhed. In the year 1782, the Antelope packet was ſhipwrecked on the Pelew iſlands, where the commander, Captain Wilſon, and his crew lived ſome time before they could get off. On his return to England, the Captain was, for ſome reaſon or other, refuſed the command of another ſhip; and, as we have been informed, he was reduced to a ſtate much the reverſe of affluence. Theſe circumſtances being communicated to Mr Keate, who was ſtruck with admiration of the manners of the inhabitants of the Pelew iſlands (See Pelew Islands, *Encycl.*), he offered to draw up, for the benefit of Captain Wilſon, a narrative of the occurrences which took place during that officer's reſidence among ſo ſingular a people. This he executed in "An Account of the Pelew Iſlands, ſituated in the Weſtern Part of the Pacific Ocean: compoſed from the Journals and Communications of Captain Henry Wilſon and ſome of his Officers, who in Auguſt 1783 were there ſhipwrecked, in the Antelope, a Packet belonging to the Honourable the Eaſt India Company," 4to; a work written with great elegance, compiled with much care, and which, if embelliſhed (as it has been inſinuated) with facts better calculated to have found a place in a novel than a genuine narrative, muſt be aſcribed to the miſinformation of thoſe who were actors in the ſcene, and muſt firſt have deceived before they obtained credit. We mention this report as it has come to us, without any attempt either to eſtabliſh or refute it. We ſhall only add, that if the charge is well founded, Mr Keate (who undertook the taſk on the moſt diſintereſted principle, and derived no advantage whatever from the work) was too ſturdy a moraliſt to have had any hand in the impoſition.—The manuſcript was offered to Mr Dodſley for 300 guineas; but he heſitated to give for it ſo large a price, when another bookſeller undertook to publiſh the work for the benefit of Mr Wilſon; and, we have reaſon to believe, paid to that gentleman, within the compaſs of a year, triple the ſum for which the manuſcript had been offered to Dodſley. Such conduct reflects honour on the London trade.

Beſides the pieces already mentioned, Mr Keate was the author of many Prologues and Epilogues, ſpoken at Mr Newcomb's ſchool at Hackney. He adapted his friend Voltaire's "Semiramis" to the ſtage; but this was ſuperſeded in 1777 at Drury Lane, by a worthleſs tranſlation of as worthleſs an author, one Captain Ayſcough; but neither this nor the author are deſerving of any further notice.

We ſhall conclude by obſerving, that Mr Keate's life paſſed without any viciſſitudes of fortune; he inherited an ample eſtate, which he did not attempt to increaſe otherwiſe than by thoſe attentions which prudence dictated in the management of it. He was hoſpitable and beneficent, and poſſeſſed the good-will of mankind in a very eminent degree. For the laſt year or two, his health viſibly declined; but on the day he died, it appeared to be ſomewhat mended. His death was ſudden, on the 27th of June 1797. He left one daughter, married in 1796 to John Henderſon, Eſq; of the Adelphi. At the time of his death, Mr Keate was a Bencher of the Temple, and a very old member of the Royal and Antiquary Societies, of both of which he had been frequently elected one of the council.

KENNICOTT (Dr Benjamin) was a man of ſuch eminence in the learned world, that every thing relating to him muſt be generally intereſting. In the biographical ſketch of him publiſhed in the *Encyclopædia*, we have acknowledged ourſelves unacquainted with the rank and character of his parents; but this information has been ſince ſupplied by a very candid and well-informed writer in the Monthly Magazine; and as it is accompanied with circumſtances peculiarly honourable to the Doctor, and ought therefore to be preſerved, we ſhall inſert it in this place. Kennicott.

"The parents of Dr Kennicott (ſays this writer) were honeſt characters: His father was the pariſh clerk of Totneſs, and once maſter of a charity ſchool in that town. At an early age young Kennicott ſucceeded to the ſame employ in the ſchool, being recommended to it by his remarkable ſobriety and premature knowledge. It was in that ſituation he wrote the verſes to the honourable Mrs Courtney, which recommended him to her notice, and that of many neighbouring gentlemen. They, with a laudable generoſity, opened a ſubſcription to ſend him to Oxford.

"He ſoon there diſtinguiſhed himſelf, as is well known. As a teſtimony of the truth of the above ſtatement, the following is a copy of an inſcription written by Dr Kennicott, and engraved on the tomb of his father and mother. The writer of this article has tranſcribed it from the original in the church-yard of Totneſs. The tomb is more elegant than perſons in their ſituation are accuſtomed to have erected, and was thought, perhaps, by the envious to be ſomewhat oſtentatious. A perſonal knowledge of the Doctor induces the writer of this article to think, that it was rather the tribute of a good and grateful mind, and of the pious reverence and love which he entertained for the authors of his being.

As Virtue ſhould be of good report,
ſacred
be this humble Monument
to the Memory of
Benjamin Kennicott, Pariſh Clerk of Totneſs,
and Elizabeth his Wife:
The latter
an Example of every Chriſtian Duty;
The former,
animated with the warmeſt Zeal,
regulated by the beſt good ſenſe,
and both conſtantly exerted
for the Salvation of himſelf and others.
Reader!
Soon ſhalt thou die alſo;
and as a Candidate for Immortality
ſtrike thy breaſt and ſay,
Let me live the life of the Righteous,
that my laſt end may be like his.
Trifling are the dates of Time
where the ſubject is Eternity.
Erected
by their Son, B. Kennicott, D. D.
Canon of Chriſt-Church, Oxford.

"It is ſaid, that when Dr Kennicott had taken orders, he came to officiate in his clerical capacity in his native

native town. When his father as clerk proceeded to place the surplice on his shoulders, a struggle ensued between the modesty of the son and the honest pride of the parent, who insisted on paying that respect to his son which he had been accustomed to shew to other clergymen: to this filial obedience was obliged to submit. A circumstance is added, that his mother had often declared she should never be able to support the joy of hearing her son preach; and that on her attendance at the church for the first time, she was so overcome as to be taken out in a state of temporary insensibility."

KERMES (see *Coccus Ilicis*, Encycl.) has been proved by Professor Beckmann to have been used as a dye from very remote antiquity. "All the ancient Greek and Latin writers, he says, agree, that kermes, called by the latter *coccum*, perhaps also *coccus*, and often *granum*, were found upon a low shrubby tree, with prickly leaves, which produced acorns, and belonged to the genus of the oak; and there is no reason to doubt that they mean *coccum ilicis*, and that low ever green oak, with the prickly leaves of the holly (*aquifolium*), which is called at present in botany *quercus ilex*. This assertion appears more intitled to credit, as the ancients assign for the native country of this tree places where it it is still indigenous, and produces kermes.

"I am inclined (continues our author) to believe, that the art of employing kermes to dye a beautiful red colour was discovered in the East at a very early period; that it was soon so much improved as to excel even the Tyrian purple; and that it contributed to cause the proper purple to be at length abandoned. From the costly red dyes extolled so much by the Hebrew writers, and which, according to the opinion of learned commentators, were made from kermes, I shall not venture to adduce any proofs, as I am not acquainted with the Oriental languages to examine their accounts with accuracy; but I have found a passage in Vopiscus, which seems to render my conjecture very probable. That author informs us, that the king of Persia sent to the Emperor Aurelian, besides other articles of great value, some woollen cloth, which was of a much costlier and brighter purple colour than any that had been ever seen in the Roman empire, and, in comparison of which, all the other purple cloth worn by the Emperor and the ladies of the court appeared dull and faded. In my opinion, this cloth, which was of a beautiful purple red colour, was not dyed with the liquor of the murex, but with kermes. This idea was indeed not likely to occur to the Romans, who were acquainted only with the purple of the murex, and who had less experience in the arts in general than in that of robbing and plundering, or who, at any rate, in that respect were inferior to the Orientals. The Roman emperors caused this supposed purple to be sought for in India by the most experienced dyers; who, not being able to find it, returned with a vague report that the admired Persian purple was produced by the plant sandix. I am well aware, that some commentators have supposed that the sandix was our madder. Hesychius, however, says, very confidently, that the *sandix* is not a plant, but a kind of shrubby tree, which yields a dye like the *coccus*. The Roman dyers, perhaps prejudiced in favour of the murex, made that only the object of their search; and their labour proving fruitless, they might have heard something of kermes, or the kermes-oak, which they did not fully understand. Our dyers, even at present, believe many false accounts respecting the dye-stuffs which they use daily."

The use of kermes in dyeing seems to have been continued through every century. In the middle ages, as they are called, we meet with kermes under the name of *vermiculus* or *vermiculum*; and on that account cloth dyed with them was called *vermiculata*. Hence the French word *vermeil*, and its derivative *vermilion*, as is well known, had their extraction; the latter of which originally signified the red dye of kermes, but it is now used for any red paint, and also for fine pounded cinnabar.

KHAS, in Bengal, lands taken into the hands of government, opposed to the management of Zemindars or farmers. See Zemindar in this *Supplement*.

KHALSA, in Bengal, sometimes with the addition of *Shereefah*, the department of land and revenues; the exchequer.

KHERAJE, in Bengal, signifies strictly the tribute paid by a conquered country: it is also used for revenue in general.

KHIDMUT, office, attendance, employment, service.

KHIDMUTGAR, a waiting man.

KHISMUT, portion or division.

KHOMAR, or Comar, a Zemindar's demesne land.

KING-POST, or King-*Piece*, is a piece of timber set upright in the middle, between two principal rafters, and having struts or braces going from it to the middle of each rafter. See Roof, *Encycl.*; and Carpentry, *Suppl.*

KIPPIS (Andrew, D. D. F. R. and A. S.), was born at Nottingham, March 28 (O. S.) 1725. His father, a respectable tradesman of that town, was descended from the Rev. Benjamin King of Oakham, Rutlandshire, an ejected minister; and his mother, Ann Ryther, was the grand-daughter of the Rev. John Ryther, who was ejected from the church of Ferby, in the county of York. In the year 1730, he lost his father, and went to reside with his grandfather, Andrew Kippis of Seaford in Lincolnshire. He received his classical education at the grammar school in that town; but what contributed most to his future eminence, was the friendship of the Rev. Mr Merrival, who was equalled by few of his contemporaries in various branches of learning, particularly in his acquaintance with the classics, his knowledge of ancient and modern history, and his refined taste in the belles lettres. Dr Kippis frequently said, that it was impossible for him to express his obligations to this friend of his youth. In 1741 he removed to Northampton, and commenced his academical studies under Dr Doddridge. After a residence of five years at the academy, he was invited by several congregations to become their minister. Though he was pressed to settle at Dorchester, and had been chosen their minister, he gave the preference to an invitation from Boston in Lincolnshire, where he went to reside in September 1746. Here he continued four years; and in November 1750, accepted the pastoral charge of a congregation at Dorking in Surry. The congregation meeting in Princes street Westminster, having been without a minister about two years, he was chosen in June 1753, to succeed the Rev. Dr Obadiah Hughes. On the 21st of September

Kippis. ber following, he married, at Boston, Miss Elizabeth Bott, one of the daughters of Mr Isaac Bott, a merchant of that place; and in the month of October fixed his residence in Westminster. In June 1767, he received the degree of D. D. from the university of Edinburgh, on the unsolicited recommendation of the late learned Professor Robertson. He was elected a member of the Society of Antiquaries on the 19th of March 1778; and on the 17th of June 1779, he was chosen a Fellow of the Royal Society. In both Societies he had the honour of being in the council two years.

Dr Kippis was eminently distinguished for the virtues and accomplishments which form the chief ornaments of private life. With a suavity of manners and urbanity of behaviour peculiarly attractive, he united that knowledge of men and books which rendered his conversation uncommonly entertaining and instructive to the circle of his acquaintance and friends. As a minister, he was not less eminent for his profound acquaintance with every branch of theology than for the happy manner in which he applied it to the improvement of those who attended his ministry. His sermons were remarkable for perspicuity, elegance, and energy; and his elocution was unaffected and very impressive, particularly at the close of his discourses. But the superior powers and vigour of mind which he derived from nature, and which he had cultivated with unremitting diligence and peculiar success, were not to be confined to the narrow limits of private life and the duties of the pastoral charge, however important; they were designed for more extensive and important services to his country and to mankind. The interests of literature, science, and religion, have received from the exertion of his talents as a writer the most essential advantages. His first efforts in literature were made in the Gentleman's Magazine, a periodical publication called the Library, and the Monthly Review; to each of which he contributed many important articles, especially in the historical and philological departments of the last. He was the author of three important tracts, viz. "A Vindication of the Protestant Dissenting Ministers, &c." "Observations on the late Contests in the Royal Society;" and "Considerations on the Treaty with America, &c." His improved edition of Dr Doddridge's Lectures is a work of great value; and "The History of Knowledge, Learning, and Taste, in Great Britain," prefixed to the New Annual Register, merits, and has received, the approbation of the public. He published at different times several single sermons; among which, that on the death of his friend the Rev. Mr Laugher, is intitled to very high praise. The greater part of these he republished, with other practical discourses, in the year 1794: but the work which, next to the studies immediately connected with his office as a Christian minister, engaged his principal attention, and by which he has long been distinguished, is, the improved edition of the "*Biographia Britannica*." In this great national publication, the comprehensiveness and powers of his mind, the correctness of his judgment, the vast extent of his information, his indefatigable researches and unremitting assiduity, his peculiar talent of appreciating the merits, and analyzing the labours of the most eminent writers, and his unshaken integrity, unbiassed fidelity, and impartial decision on the characters of the philosopher, statesman, poet, scholar, and divine, are strongly displayed, and universally acknowledged. His style, formed on the models of Sir William Temple and the classical Addison, is remarkable for its perspicuity, elegance, and purity; and gives a peculiar lustre to the rich stores of knowledge treasured in the volumes now published. This work has given him a high rank among the literati of his country, and will carry down his name with distinguished reputation to posterity. He died on the 8th October 1795.

Kol KOL-QUALL, the Abyssinian name of a tree, which some botanists have supposed to be the EUPHORBIA *Officinarum* of Linnæus. Mr Bruce, who gives the only description of the Kol-quall that we have seen, is of a different opinion: for which he assigns two reasons; the first is, that the flower, which he says is rosaceous, is composed of several petals, and is not companiform; and the second, that it produces no sort of gum, either spontaneously or upon incision. We must acknowledge, that we entertain some doubts whether our author was at due pains to ascertain this fact; and these doubts are suggested by his own history of the tree. His description is not very perspicuous, and therefore, lest we should misrepresent his meaning, we shall give it in his own words:

"The first thing that presented itself was the first shoot of this extraordinary tree. It was a single stalk, about six inches measured across, in eight divisions, regularly and beautifully scolloped and rounded at the top, joining in the centre at three feet and a half high. Upon the outside of these scollops were a sort of eyes or small knots, out of every one of which came five horns, four on the sides and one in the centre, scarce half an inch long, fragil, and of no resistance, but exceedingly sharp and pointed. Its next process is to put out a branch from the first or second scollop near the top, others succeed from all directions; and this stalk, which is soft and succulent, of the consistence of the aloe, turns by degrees hard and ligneous, and after a few years, by multiplying its branches, assumes the form of a tree, the lower part of which is wood, the upper part, which is succulent, has no leaves; these are supplied by the fluted, scolloped, serrated, thorny sides of its branches. Upon the upper extremity of these branches grow its flowers, which are of a golden colour, rosaceous, and formed of five round or almost oval petals; this is succeeded by a triangular fruit, first of a light green with a slight cast of red, then turning to a deep crimson, with streaks of white both at top and bottom. In the inside it is divided into three cells, with a seed in each of them; the cells are of a greenish white, the seed round, and with no degree of humidity or moisture about it; yet the green leaves contain a quantity of bluish watery milk almost incredible.

"Upon cutting two of the finest branches of a tree in its full vigour, a quantity of this issued out, which I cannot compute to be less than four English gallons; and this was so exceedingly caustic, that though I washed the sabre that cut it immediately, the stain has not yet left it.

"When the tree grows old, the branches wither, and, in place of milk, the inside appears to be full of powder, which is so pungent, that the small dust which I drew upon striking a withered branch, seemed to

threaten

threaten to make me freeze to death, and the touching of the milk with my fingers excoriated them as if scalded with boiling water; yet I everywhere observed the wood pecker piercing the rotten branches with its beak, and eating the insects, without any impression upon its olfactory nerves."

If what is milk in a young tree be a dry powder in one that is old, is it not probable that the milk might by evaporation be reduced to the consistence of gum, and that the kol quall may be at most but a variety of the *euphorbia officinarum?* From our author's observation, the kol-quall appeared to thrive best on poor, sandy, stony earth, at no great distance from the sea. The Abyssinians employ the milky juice in tanning to take off the hair from the skins, and they make no other use whatever of the tree.

KOONA, a species of ECHITES (for which see *Encycl.*), very common in the woods of North Africa. It is a shrub, of which the leaves, when boiled with a small quantity of water, yield a thick black juice, into which the negroes dip a cotton thread. This thread they fasten round the iron of their arrows, in such a manner that it is almost impossible to extract the arrow when it has sunk beyond the barbs, without leaving the iron and the poisoned thread in the wound. The poison of the koona is said to be very deadly.—*Park's Travels.*

KORAQUAS, a tribe of Hottentots inhabiting a district of South Africa, which M. Vaillant places on the confines of the Nimiqua country (See NIMIQUAS, *Suppl.*). When our author visited them, the whole tribe was assembled for the election of a chief; and not agreeing among themselves, some blood had been shed, and much more would have been shed, had they not unanimously made choice of him. When he first joined them, the whole horde paid attention to nothing but their quarrel. To see their warmth, one might have supposed that their election was a matter of importance to the whole world, and that the fate of mankind was about to depend on their chief. All spoke at the same time; each endeavoured to drown his neighbour's voice by his own; their eyes sparkled with fury; and amidst this confusion, while they threatened each other in turns, the noise they made became truly dreadful.

Unarmed, and without any precaution, though surrounded by this enraged multitude, our author walked calmly along in the midst of them; and when he reached the kraal, he ordered his tent to be immediately formed, as if he had been surrounded by friends and relations. This appearance, raised suddenly, and as if by magic, before the eyes of the horde, with his fusees, horses, and tent, objects which were all new to them, filled them with admiration. Men, women, and children, motionless, and with their mouths wide open, all stood looking at them with profound silence. Anger, hatred, and every violent passion, seemed by their countenances to be extinguished; and to have given place to more tranquil emotions, to ignorant surprise, and stupid astonishment. Infancy is naturally curious; it is struck with every thing it sees; and the savage, in this respect, is only a grown-up child. As these savages seemed to wish that he would permit them to examine more closely whatever excited their admiration, he readily condescended to gratify their desire. They approached, surveyed, and handled every thing. But the principal object of general curiosity was his person. They seemed as if they would never be satisfied with looking at his dress. They pulled off his hat, that they might the better examine his hair and his beard, which were long. They even half unbuttoned his clothes; and surprised to see his skin white, each felt it, as if desirous to ascertain that what they saw was real.

This comedy continued till the evening; and at length, when the moment of separation arrived, M. Vaillant caused to be hinted to the whole company, that if, two hours after sun rise next morning, they should not be agreed respecting the choice of a chief, he would immediately leave them. He added, however, that if, on the other hand, they came and presented to him a chief, elected by general consent, he would then load them all with presents, and bestow on him a distinction which would raise him above all his equals, and render the horde one of the most celebrated in the whole country. "But what was my surprise (says he) when I learned the same evening, that on my head the burden of the crown was deposed!" He acquiesced, however; assuring them, that if they would promise to be obedient, he would give them the only chief worthy of ruling them, and of making them happy.

By his interpreters he had learned, that the choice of the majority leaned towards one Haripa, a man about 40 years of age; tall, well made, exceedingly strong, and consequently formed by nature for ruling the feeble multitude. He therefore named Haripa chief; and the people appearing to approve of his choice, he commanded silence, and causing the new monarch to approach, placed on his head, with great solemnity, a Dutch grenadier cap, of which the copperplate on the front was ornamented with the arms of Holland. This symbol, *viz.* a lion rampant, having in one of his fore-paws seven arrows, and in the other a naked sabre, could not fail to please the savages, as it exhibited a representation of the weapons peculiar to them, and of the most formidable animal of their country. They testified their admiration in the most expressive manner; and imagined that, superior to kings, the white man during the night had by magic made this crown, merely to adorn their chief, and to afford them pleasure. Vaillant then affixed to the skin, which formed Haripa's dress, several rows of glass beads; gave him a girdle made of a string of very large ones; ornamented his arms with tin bracelets, and suspended from his neck a small padlock, shaped like a butterfly, the key of which had been lost. Such padlocks, made in the form of animals of every kind, are very common at the Cape. They come from China; and are brought to Africa by the captains of the Company's ships which trade in the Indian seas.

During the ceremony of installation, the whole horde, dumb and motionless through admiration, seemed lost in ecstacy. Haripa himself, though highly gratified, did not dare to make the least movement, and observed a gravity altogether risible. When the inauguration was finished, and he was completely dressed, our author presented him with a mirror, that he might enjoy the satisfaction of surveying his own figure. He then shewed him to the people, who expressed their joy by shouts and applauses without end.

"Ye honest hearts (says M. Vaillant), who peruse this account, behold what it cost me to restore peace among

Koraquas. among a whole tribe, and to prevent them from destroying each other!" From this moment concord was re-established; universal joy prevailed through the horde; and they instantly began their dancings, which continued for three days and three nights without intermission. They killed for this festival several fat sheep, and even two oxen; an extraordinary and truly astonishing magnificence among a people who, when they barter one of their daughters for a cow, think they have made an excellent bargain.

Our author, wishing to purchase some oxen for his waggons, bought them at the price of a nail the ox; and those who had the good fortune to make such an exchange were highly satisfied with their bargain. Nails and small bits of iron were indeed of real value to them, to point the arrows and assageys, with which they shot the antelopes that abound in their country, and constitute much of their food. Like other savages, the Koraquas were ready to pilfer, and appropriate to their own use whatever they found pleasing, or suited to their purposes. They attempted to carry away some of our author's effects, even before his face; and to prevent their rapacity, he was obliged either to watch over, or to deposit them in some place of safety.

The Koraquas are much taller than the Hottentots of the colonies, though they appeared evidently to be descended from the same race, having the same language and customs with their neighbours the NIMIQUAS (see that article), who are certainly of Hottentot extraction.

As the excessive dryness of the country renders springs very rare, the Koraquas would be unable to inhabit it, had they not found the means of remedying this scarcity of water. For this purpose they dig in the earth a kind of cisterns or rather wells, to which they descend gradually by steps; and these people are the only African nation among whom our author ever found the same mark of industry.

As their wells always contain little water, and as none is to be lost, they take care to secure it even from the birds, by closing up the mouth of the hole with stones and the branches of trees; so that, unless one knows the spot, it is impossible to find it. They go down into it every day, to fetch up as much water as may be necessary for the consumption of their people and cattle. They draw it in a kind of vessels made of hollowed wood, and pour it into the skins of buffaloes or giraffes, placed in a concave form on the ground to hold it; but they distribute it with the utmost parsimony, and never draw more than they absolutely have occasion for.

Notwithstanding this strict economy, the wells often become dry; and in that case the horde is obliged to remove to some other place. Among all the western tribes, therefore, there are none who lead so wandering a life as the Koraquas: the consequence of which is, that, as they often change their abode, and acquire new neighbours, they must, in some measure, adopt the customs of the nations near which they fix their residence. Some tribes of them grease themselves like the Hottentots; while others tattoo their face, breast, and arms, after the manner of the Caffres. It is, however, to be remarked, that the same colour is not employed by all the Koraquas; each has his own, according as caprice may direct him in his choice, and it generally varies every day; which renders, as one may say, the inhabitants of the same horde strangers to each other, and gives them a motley appearance, as if they were dressed for a masquerade.

Krishna. KRISHNA or CRISNA, is an eastern river of considerable magnitude, which is very little known in Europe. We have the following account of it, and its tributary waters, and the countries through which it flows, in Mr Pennant's View of Hindustan:

"From Gangapatam, on the northern mouth of the Pennar, the land runs due north as far as Mottapilli, when it forms a strong curve toward the east; the point of which is one side of the great river Crisna, in about lat. 15° 43'. Its Delta, which winds round as far as Masulipatam, is not considerable. This river annually overflows a vast tract of country, like the Indus on the western side of this empire, and like all the other great rivers on this extensive coast. The Crisna rises from the foot of the western Ghauts, and not more than 45 miles from Severndrug, on the western coast. There is another branch to the east, that rises still more northerly. On that side is Sattara, a strong fortress, the capital of the Mahratta state in the time of the rajahs of Sivaji's race. It was taken by him in 1673, and found to be the depository of immense treasure; at that time it belonged to the king of Vijapur: it was afterwards used by the Mahrattas as the lodgment of their riches, and also as a retreat for the more defenceless inhabitants of Puna, and other open towns, in time of potent invasions.

"The river continues descending to the east. In latitude 17° is Meritch, a strong fortress, with a Jaghirdar territory, conquered from its owner by Hyder. In lat. 16° 45', a small river discharges itself into the Crisna from the north. It would not be worth mentioning, but that Pannela, a fortress of vast strength, was made by Sumbuji, the profligate son of Sivaji, his residence just before his surprisal in 1689, betrayed by Cablis Khan, the vile instrument of his pleasures corrupted by Aurengzebe. His extravagant love of women brought on him ruin. Informed by Cablis that a Hindu of rank and great beauty was on the road to be delivered by her parents to her husband, according to the custom of the Hindus, he instantly put himself at the head of a small body of horse to carry off the prize, and ordered Cablis to follow at a distance for his protection, in case of accidents in that hostile time. The traitor had given notice to Aurengzebe of this expedition, who, sending a body of cavalry, surprised Sumbuji just as he had dispersed the nuptial procession.

"Into the north side of the Crisna, in lat. 16° 25', falls the great river Bima, after a course of 350 miles. It rises at the head of the western Ghauts, parallel to Chaul in the Concan, and not above 50 miles from the sea. It descends rapidly towards the south-east. In lat. 17° 40' it receives a small river from the west, on the southern banks of which stands Vijapur, the capital of the famous kingdom of the same name, now possessed by the Mahrattas, but once governed by its own monarchs, till conquered by Aurengzebe in 1686. It was of great extent, and reached to the western sea, where it possessed the ports of Dabul, Vingorla, and Carapatan.

"The capital Vijapur is some leagues in circuit, seated in a fine but naked country, well watered. It makes a singular appearance from an adjacent eminence, filled with numbers of small domes, and one of a majestic size.

size. It was once a city of great splendour, and filled with palaces, mosques, mausoleums, and public and private buildings of great magnificence; many of them are fallen to ruin, and give melancholy proofs of its former splendour. I shall not attempt to detail them. The palaces of the kings, and accommodations for their attendants, were within a vast fort, surrounded with a ditch 100 yards wide; the depth appeared to be great, but is now filled with rubbish: within the fort is the citadel. Tavernier says, that the great ditch was filled with crocodiles, by way of garrison, to prevent all access by water. Lieutenant Moor has his doubts about this, imagining that there never was any water in this fosse. That such garrisons have existed I doubt not. I have read in Purchas, that in Pegu the fosses of fortified places were stocked with those tremendous animals, not only to keep out enemies, but to prevent desertion. This practice has certainly been of great antiquity in some parts of India: Pliny mentions it as used in a fair city of the Horatæ, a people I cannot trace.

"The Crisna, above and below its conflux with the Bima, is fordable; and a few miles below its channel is 600 yards wide, made horrid with the number and rudeness of the variously formed rocks, which are never covered but in the rainy season.

"The Tungbuddra is another vast branch of the Crisna. It falls into it in lat. 16° 25', and originates extremely south, from a doubtful fountain. Towards its lower part it divides into three or four small branches, which rise remote from each other; the most southern is the Curga Nair's country; the most northern from the head of the Ghauts opposite to Onor, and scarcely 20 miles from the sea. What must give this river great celebrity, is its having had on its banks, in lat. 15° 22', the splendid city of Vijanagar. Ferishta says, that it was founded in 1344 by Belaldeo king of the Carnatic, which in those days included the whole peninsula. It was visited by Cæsar Frederick a Venetian traveller, in 1565, and found deserted and ruinous; having been sacked by four confederated Mahomedan princes two years before, on which its monarch had retired to Penuconda. Frederick says that its circumference was 24 miles. Mr Rennel has given us a view of its present state from Lieutenant Emitt, who visited it in 1792.

"The ruins of Vijanagar are in the little Sircar of Anagundi, which does not extend above 20 miles around this vast city. It is very singular, that that little Sircar is now possessed by a lineal descendant of Rama Rajah, the last great monarch of Vijanagar, and its attendant nations Canarine and Malabar, united 700 years before under the rule of Crisna Deva. Tippu wished to reserve this little tract to himself, for the satisfaction of generously restoring to the descendant the small relique of the great empire of his ancestors. He is denied the title of Rajah, instead of which he has the diminutive Rail bestowed on him. This is suitable to his revenues, which do not exceed two lacs of rupees, or 25,000 *per annum*, with the empty regality of a mint at Anagundi." In the remainder of its course the Crisna offers nothing remarkable.

KUARA, is a beautiful tree, which grows in the south and south-west parts of Abyssinia. With the ebony it is almost the only wood of the province of Kuara, of which it bears the name; but Mr Bruce assures us, that it is very frequent in all the countries where there is gold. "It is (says he) what naturalists call *a Corallodendron*, probably from the colour of its flowers or of its fruit, both equal in colour to coral. Its fruit is a red bean, with a black spot in the middle of it, which is inclosed in a round capsula or covering, of a woody nature, very tough and hard. This bean seems to have been in the earliest ages used for a weight of gold among the Shangalla, and, where that metal is found, all over Africa; and by repeated experiments, I have found that, from the time of its being gathered, it varies very little in weight, and may perhaps have been the very best choice that therefore could have been made between the collectors and buyers of gold.

"I have said this tree is called kuara, which signifies the sun. The bean is called *carat*, from which is derived the manner of esteeming gold as so many carats fine. From the gold country in Africa it passed to India, and there came to be the weight of precious stones, especially diamonds; so that to this day in India we hear it commonly spoken of gold or diamonds, that they are of so many carats fine or weight. I have seen these beans likewise from the West-Indian islands. They are just the same size, but, as far as I know, are not yet applied to any use there."

This is a very different account of the origin of the term CARAT from what we have given in the *Encyclopædia*; but the reader will judge for himself between the two.

KUMI, the name of an island between Japan and China, of which Perouse writes in the following terms: "On the 5th of May, at one o'clock in the morning, we made an island, which bore north north east of us; we passed the rest of the night, standing off and on, under an easy sail, and at day-break I shaped my course so as to run along the west coast of this island, at the distance of half a league. We sounded several times without finding bottom. We were soon satisfied that this island was inhabited, for we saw fires in several places, and herds of oxen grazing on the sea-shore. When we had doubled its west point, which is the most beautiful and best inhabited side, several canoes put off from the shore in order to observe us. They seemed to be extremely in fear of us; their curiosity caused them to advance within musket shot, and their distrust made them immediately flee away with speed. Our shouts, gestures, signs of peace, and the sight of some stuffs, at length determined two of the canoes to come alongside of us. I made each of them a present of a piece of nankeen and some medals. It was evident that these islanders had not left the coast with any intention of trafficking with us, for they had nothing to offer in exchange for our presents; they only fastened to a rope a bucket of fresh water, making signs to us, that they still thought themselves in our debt, but that they were going ashore to fetch provision, which they expressed by putting their hand into their mouth. Before coming alongside the frigate, they placed their hands upon their breast, and raised their arms towards the sky: these gestures were repeated by us, and then they resolved to come on board; but it was with a want of confidence, which was strongly expressed in their countenance during the whole time. They nevertheless invited us to approach the land, giving us to understand, that we should there want for nothing. These islanders are

are neither Japanese nor Chinese, but, situate between these two empires, they seem to partake of both people. Their covering was a shirt and a pair of cotton drawers. Their hair, tucked up on the crown of the head, was rolled round a needle, which seemed to us to be gold: each of them had a dagger, the handle of which was gold also. Their canoes were made out of hollowed trees, and they managed them very indifferently. I could have wished to land upon this island, but as we had brought the ship to, in order to wait for these canoes, and as the current set to the northward with extreme rapidity, we had drifted a great way to leeward, and our efforts to reach it would perhaps have been in vain: besides, we had not a moment to lose, and it was of the highest importance to us to get out of the Japan seas before the month of June; a period of storms and hurricanes, which render these seas the most dangerous in the whole world.

"It is clear, that vessels which might be in want would readily provide themselves with provision, wood, and water, in this island, and perhaps even carry on a little trade; but as it is not more than three or four leagues in circumference, there is no great probability that its population exceeds four or five hundred persons; and a few gold needles are not of themselves a proof of wealth." Our author, by observation, found the latitude of Kumi to be 24° 33′ north; its longitude 120° 56′ east from Paris.

KURILES, are a cluster of islands, of which some account has been given under the word KURILI in the *Encyclopædia*. In addition to that article, the following particulars are worthy of notice: Of the 21 islands belonging to Russia, which are distinguished from each other, not by names, but by numbers, four only are inhabited, viz. those which are called the first, the second, the thirteenth, and the fourteenth. The last two may indeed be counted only as one, because the inhabitants all pass the winter upon N° 14, and return to N° 13 to pass the summer months. The others are entirely uninhabited, the islanders only landing there occasionally from their canoes for the sake of hunting foxes and otters. Several of these last mentioned islands are no better than large rocks; and there is not a tree on any one of them. The currents are very violent between the islands, particularly at the entrance of the channels, several of which are blocked up by rocks on a level with the sea. The population of the four inhabited islands amounts at most to 1400 souls. The inhabitants are very hairy, wear long beards, and live entirely upon seals, fish, and the produce of the chace. When visited by M. Perouse, they had just been exempted for ten years from the tribute usually paid to Russia, because the number of otters on their islands is very much diminished. These poor people are good, hospitable, and docile, and have all embraced the Christian religion. The more southern and independant islanders sometimes pass in canoes the channels that separate them from the Russian Kuriles, in order to give some of the commodities of Japan in exchange for peltries.

L.

Labdasseba. LABDASSEBA, a tribe of savage Arabs, who inhabit the desart of Sahara in Africa. They are the most powerful of all those tribes except the Ouadelims; and they resemble these so much in every thing, that we shall give an account of the manners of both under the title OUADELIMS, and of their country under that of SAHARA.

LABORATORY, is an apparatus so necessary to the chemist, that every contrivance to render it more convenient, or to lessen the expence of it, must contribute greatly to the advancement of science. The abilities of *Morveau* alias *Guyton*, and the success with which he has prosecuted the study of chemistry, are well known; and therefore his different methods of saving time and expence in making chemical experiments must be worthy of the notice of younger chemists.

In the second volume of the Memoirs of the Ancient Academy of Dijon, we have a description by him of a box containing a kind of portable laboratory, composed of a lamp with three wicks, disposed in the figure of an equilateral triangle, to form an internal current of air, with supports for the different vessels of digestion, distillation, evaporation, &c. He made a solution of silver with common aqua fortis and the metal in an alloyed state, which answered very well as a re-agent, without having occasion for any other utensils but this box and apothecary's phials, which are every where to be found.

This apparatus, however, was confined in its application, and he soon thought of improving it. He constructed a lamp, on the principles of Argand, with three concentric circular wicks, each having an interior and exterior current of air. The effect surpassed his expectations with regard to the intensity of the heat; but it was difficult to prevent the destruction of the hard solder round the wicks; and the glass retorts were frequently melted at the bottom, and disfigured. It was attended with other inconveniences, and the quantity of oil consumed was great.

A short time afterwards, it occurred him to substitute, instead of the glass chimney of Argand's lamp, a cylinder of copper with an indented part or ledge a few millimetres (see REVOLUTION, *Encycl.* n° 183.) above the flame, to perform the office of the indented chimney of glass, and by that means to render it practicable to raise the wick to a certain height without smoaking. This cylinder has three branches like a chaffing-dish. By this apparatus two or three decilitres of water (about half an English wine pint) may be brought to boil in a copper or glass vessel in about six or seven minutes. It has served for a number of operations; but it was not till after he had observed the degree of heat obtained from the lamp in its ordinary state, and particularly since he had substituted instead of the metallic tube a chimney of glass cut off at the length of three

Laboratory.

centimetres (rather more than one English inch) above the contraction, that he perceived all the advantages it was capable of affording; and that by means of a moveable support for the reception of the different vessels, which may be fixed at pleasure by a thumb-screw, this lamp furnace, at the same time that it gives light, and consequently without any additional expence, may with facility be used for almost every one of the operations of chemistry; such as digestions, solutions, crystallizations, concentrations; the rectification of acids; distillations on the sand-bath, or by the naked fire; incinerations of the most refractory residues; analyses with the pneumatic apparatus, or of minerals by the saline fusion, &c. "I have not (says he) hitherto met with any exception but for complete vitrifications and cupellations; for even the distillations to dryness may be performed with some precautions, such as that of transferring the matter into a small retort blown by the enameller's lamp, and placing its bottom on a little sand-bath in a thin metallic dish." The support here mentioned is simply a copper ring eight centimetres (3,15 inch.) in diameter, which is raised or lowered by sliding on a stem of the same metal. Nothing more was required but to adapt it to the square iron stem which passes through the reservoir of the lamp. The connection is made by a piece of wood, in order that less of the heat might be dispersed. As the lamp itself is capable of being moved on its stem, it is easy to bring it nearer or remove it at pleasure from the vessels, which remain fixed; a circumstance which, independent of the elevation or depression of the wick, affords the means of heating the retorts by degrees, of moderating or suppressing the fire instantly, or of maintaining it for several hours at a constant or determinate intensity, from the almost insensible evaporation of crystallizable solutions to the ebullition of acids; properties never possessed by the athanor, of which chemists have boasted so much. The advantage of these will be properly valued by those operators who know that the most experienced and the most attentive chemists meet with frequent accidents, by which both their vessels and the products of their operations are lost for want of power in the management of the fire."

For the analysis of stones, such as the crystals of tin, the shortened chimney of glass is to be used; and the process is to be begun by placing the mixture in a capsule of platina or silver $2\frac{1}{4}$ inches in diameter. This capsule is to be placed on the support, and the heat regulated in such a manner, that ebullition shall take place without throwing any portion of the matter out of the vessel. As soon as its contents are perfectly dry, they are to be transferred into a very thin crucible of platina, of which the weight is about $252\frac{1}{2}$ grains English, and its diameter one inch and three-fourths. This crucible rests on a small support of iron-wire, which serves to contract the ring; and the wick being at its greatest elevation, with the ring lowered to the distance of $9\frac{1}{4}$ inches from the upper rim of the chimney, Guyton produced, in less than twenty minutes, the saline fusion to such a degree, that from the commencement of the operation the decomposition proceeded as far as to 0.70 of the mineral. The same apparatus, that is to say, with the shortened chimney, serves for oxidations, incinerations, torrefactions, and distillations to dryness.

In such operations as require a less heat, he leaves the lamp with its large chimney absolutely in the same state as when it is used for illumination; and by raising and lowering either the ring which supports the vessel, or the body of the lamp if the vessels be fixed in communication with others, he graduates the heat at pleasure. Vinegar distils without interruption at $2\frac{1}{4}$ inches English from the upper termination of the chimney, that is to say, $7\frac{1}{4}$ inches English from the flame. Water is made to boil in eight minutes, at the same height, in a glass vessel containing one wine pint English, and is uniformly maintained at the distance of $8\frac{1}{4}$ inches from the flame.

"I must not in this place (says our author) omit to mention a slight observation which this process has afforded, because it may lead to useful applications, and tends to point out one great advantage of this method of operating; namely, that an infinity of circumstances may be perceived, which might not even be suspected when the whole process is carried on within a furnace. I have remarked, as did likewise several of my colleagues who were then present, that a column of bubbles constantly rose from a fixed point of the retort on one side of the bottom. We were of opinion, that some particle of matter was in that place incorporated with the glass, which had a different capacity for heat from that of the rest of the glass. In order to verify this conjecture, I endeavoured the following day to distil the same quantity of the same water in the same retort, after having introduced a button of cupelled silver, weighing nine decigrammes (20½ grains). At the commencement of the operation there was a small stream of bubbles from the same point as before; but a short time afterwards, and during the whole remaining time of operating, the largest and most incessant stream of bubbles rose from the circumference of the button, which was often displaced by the motion; and in proportion to the time the product of the distillation was sensibly greater. Whence we may conclude, that metallic wires or rods, distributed through a mass of water required to be kept in a state of ebullition, and placed a little below its surface, would produce, without any greater expence of fuel, nearly the same effect as those cylinders filled with ignited matter which are made to pass through the boilers."

We have related this fact in Guyton's own words, or at least in a faithful translation of them; and we are far from calling it in question, for it is a fact which has been often observed; but we think his inference from it too hastily drawn. It is not conceivable, that heat can be more rapidly conveyed through a mass of liquid by the conducting power of metal, than by a free circulation; but we agree with what seems to be Mr Nicholson's opinion *, that the thin stratum of water beneath the button becomes more suddenly and violently elastic than elsewhere, and therefore rises regularly to the surface. The whole of this phenomenon the reader will find explained in our article STEAM (*Encycl.*), n° 10. But this is a digression.

We return therefore to Guyton's laboratory, of which the reader will form a distinct notion from plate XXXIII. where fig. 1. represents the whole apparatus ready mounted for distillation, with the tube of safety and a pneumatic receiver. A is the body or reservoir of the usual lamp of Argand, with its shade and glass chimney. The lamp may be raised or lowered at pleasure by means of the thumb screw B, and the wick rises

* *Journal*, August 1798, note, page 212.

and falls by the motion of the small toothed wheel placed over the waste cup. This construction is most convenient, because it affords the facility of altering the position of the flame with regard to the vessels, which remain fixed; and the troublesome management of bended wires above the flame for the support of the vessels is avoided, at the same time that the flame itself can be brought nearer to the matter on which it is intended to act. D, a support consisting of a round stem of brass, formed of two pieces which screw together at about two-thirds of its height. Upon this the circular ring E, the arm F, and the nut G slide, and are fixable each by its respective thumb screw. The arm also carries a moveable piece H, which serves to suspend the vessels in a convenient situation, or to secure their position. The whole support is attached to the square iron stem of the lamp by a piece of hard wood I, which may be fixed at any required situation by its screw. K represents a stand for the receivers. Its moveable tablet L is fixed at any required elevation by the wooden screw M. The piece which forms the foot of this stand is fixed on the board N; but its relative position with regard to the lamp may be changed by sliding the foot of the latter between the pieces OO. P, another stand for the pneumatic trough. It is raised or lowered, and fixed to its place, by a strong wooden screw, Q. R is a tube of safety, or reversed syphon, which serves, in a great measure, to prevent the bad effects of having the vessels either perfectly closed, or perfectly open. Suppose the upper bell-shaped vessel to be nearly of the same magnitude as the bulb at the lower end of the tube, and that a quantity of water, or other suitable fluid, somewhat less than the contents of that vessel, be poured into the apparatus. In this situation, if the elasticity of the contents of the vessels be less than that of the external air, the fluid will descend into the bulb, and atmospheric air will follow and pass through the fluid into the vessels; but, on the contrary, if the elasticity of the contents be greater, the fluid will be either sustained in the tube, or driven into the bell-shaped vessel; and if the force be strong enough, the gaseous matter will pass through the fluid, and in part escape.

Fig. 2. Shews the lamp furnace disposed to produce the saline fusion; the chimney of glass shortened; the support D turned down; the capsule of platina or silver S placed on the ring very near the flame.

Fig. 3. The same part of the apparatus, in which, instead of the capsule, a very thin and small crucible of platina T is substituted, and rests upon a triangle of iron wire placed on the ring.

Fig 4. Exhibits the plan of this last disposition.

LACERTA, in astronomy. See ASTRONOMY, n° 406. *Encycl.*

LACMUS, a dye stuff prepared by the Dutch from the LICHEN ROCELLA, which see in this *Supplement*.

LACSHA, the Indian name of the lac insect, which has been described in the *Encyclopædia* under the title COCCUS, *Species* 5. Since that article was published, a description of that insect, which is more to be depended upon, has been given to the world in the second volume of the Asiatic Researches. It is by Mr Roxburgh, surgeon on the Madras establishment, and was communicated to the Society by Dr James Anderson physician at Fort St George, who observes, that Mr Roxburgh's discovery will bring the lacsha as a genus into the class *Hemiptera* of Linnæus.

"Some pieces of very fresh-looking lac (says Mr Roxburgh) adhering to small branches of mimosa cinerea, were brought me from the mountains on the 20th of November 1789. I kept them carefully, and today, the 4th of December, fourteen days from the time they came from the hills, myriads of exceedingly minute animals were observed creeping about the lac and branches it adhered to, and more still issuing from small holes over the surface of the cells: other small and perforated excrescences were observed with a glass amongst the perforations, from which the minute insects issued, regularly two to each hole, and crowned with some very fine white hairs. When the hairs were rubbed off, two white spots appeared. The animals, when single, ran about pretty briskly, but in general they were so numerous as to be crowded over one another. The body is oblong, tapering most towards the tail, below plain, above convex, with a double, or flat margin: laterally on the back part of the thorax are two small tubercles, which may be the eyes: the body behind the thorax is crossed with twelve rings: legs six; feelers (antennæ) half the length of the body, jointed, hairy, each ending in two hairs as long as the antennæ: rump, a white point between two terminal hairs, which are as long as the body of the animal. The mouth I could not see. On opening the cells, the substance that they were formed of cannot be better described, with respect to appearance, than by saying it is like the transparent amber that beads are made of: the external covering of the cells may be about half a line thick, is remarkably strong, and able to resist injuries: the partitions are much thinner: the cells are in general irregular squares, pentagons and hexagons, about an eighth of an inch in diameter, and one quarter deep: they have no communication with each other. All those I opened during the time the animals were issuing, contained in one half, a small bag filled with a thick red jelly like liquor, replete with what I take to be eggs: these bags, or utriculi, adhere to the bottom of the cells, and have each two necks, which pass through perforations in the external coat of the cells, forming the fore-mentioned excrescences, and ending in some very fine hairs. The other half of the cells have a distinct opening, and contain a white substance, like some few filaments of cotton rolled together, and numbers of the insects themselves ready to make their exit. Several of the same insects I observed to have drawn up their legs, and to lie flat: they did not move on being touched, nor did they shew any signs of life with the greatest irritation.

"*December* 5. The same minute hexapedes continue issuing from their cells in numbers: they are more lively, of a deepened red colour, and fewer of the motionless sort. To-day I saw the mouth: it is a flattened point about the middle of the breast, which the little animal projects on being compressed.

"*December* 6. The male insects I have found to-day: a few of them are constantly running among the females most actively: as yet they are scarce more, I imagine, than one to 5000 females, but twice their size. The head is obtuse; eyes black, very large; antennæ clavated, feathered, about ⅔ds the length of the body: below the middle an articulation, such as those in the legs: colour between the eyes a beautiful shining green: neck very short: body oval, brown: abdomen oblong, the length of body and head: legs six: wings membranaceous, four, longer than the body, fixed to the sides of the

the thorax, narrow at their growing broader for ⅔ds of their length, then rounded the anterior pair is twice the size of the posterior: a strong fibre runs along their anterior margin they lie flat, like the wings of a common fly when it walks or rests; no hairs from the rump: it springs most actively to a consider able distance on being touched: mouth in the under part of the head: maxillæ transverse. To day the female insects continue issuing in great numbers, and move about as on the 4th.

"*December 7.* The small red insects still more numerous, and move about as before: winged insects, still very few, continue active. There have been fresh leaves and bits of the branches of both *Mimosa Cinerea* and *Corinda* put into the wide mouthed bottle with them: they walk over them indifferently, without shewing any preference, or inclination to work or copulate. I opened a cell whence I thought the winged flies had come, and found several, eight or ten, more in it, struggling to shake off their incumbrances: they were in one of those utriculi mentioned on the 4th, which ends in two mouths, shut up with fine white hairs, but one of them was open for the exit of the flies; the other would no doubt have opened in due time: this utriculus I found now perfectly dry, and divided into cells by exceeding thin partitions. I imagine, before any of the flies made their escape, it might have contained about twenty. In these minute cells with the living flies, or whence they had made their escape, were small dry dark coloured compressed grains, which may be the dried excrements of the flies."

LAMANON (Robert Paul), of the academy at Turin, correspondent of the Academy of Sciences at Paris, and member of the Museum in the same city, was born at Salon in Provence, in 1752, of an old and respectable family. Being a younger son, he was destined for the church, and sent to Paris to complete his theological studies; but getting acquainted with the philosophers (as they called themselves), he soon lost all relish for the study of theology, and devoted himself to the physical sciences, especially those of chemistry and mineralogy. Into the church, however, he got, and rose to the dignity of canon; but by the death of his father and elder brother, having acquired the right of directing his own future exertions, he hastened to quit a profession, towards which he felt no partiality.

A prelate, then in high favour at court, hearing of Lamanon's intention of quitting his office of canon, offered him a considerable sum, to induce him to resign in favour of one of his dependents. The chapter of Arles, replied our young ecclesiastic, did not sell me my benefice, I shall therefore restore it in the same manner that I received it. This conduct was certainly meritorious; and his eulogist *Ponce* mentions another trait of his character, which sets him in a very amiable point of view; he refused to accept of his paternal inheritance, otherwise than as an equal sharer with his brothers and sisters.

Thus liberated from the trammels of his former profession, Lamanon applied himself with uncommon ardour to study. Eager to raise the awful veil that conceals from our eyes the secrets of nature; persuaded, that even the greatest genius only amuses itself with false systems in the silence of a cabinet; convinced of the necessity of much and various observation, and of surprising Nature, as it were, in the very fact, in order to penetrate into the sublimity of her operations; our young philosopher travelled through Provence and Dauphine, and scaled the Alps and Pyrenees. At the sight of these vast natural laboratories the bent of his mind burst forth instantaneously: he climbed to the summit of rocks, and explored the abyss of caverns, weighed the air analysed specimens, and, in his ardent fancy, having attained the secrets of creation, he formed a new system of the world. On his return home, he applied with additional interest to the study of meteorology, mineralogy, natural philosophy, and the other branches of the history of nature.

Lamanon.

Whilst he was meditating a visit to Paris for the purpose, as his eulogist expresses himself, of conversing with the luminaries of science, the inhabitants of the commune of Salon, having lost a cause against their lord, unanimously elected Lamanon, with whose integrity and abilities they were well acquainted, to go and solicit of the council the repeal of an unjust decree that had been obtained by partiality. The reply of the young philosopher on this occasion is an additional proof of his uncommon disinterestedness. "As I intend (said he) to go to Paris on business of my own, I cannot think of accepting your offer of 24 livres daily pay: a twelfth of this sum will cover the extraordinary expences of the journeys that I shall be obliged to make to Versailles on your account." He had the satisfaction of complete success in the business thus undertaken.

Having satisfied his curiosity in Paris, he went over to England. During the passage, though much incommoded by sea-sickness, and in imminent hazard of being overwhelmed by the tumbling waves of a very stormy sea, he caused himself to be tied to the main-mast, in order to contemplate at leisure so grand and fearful a spectacle. The bursts of thunder, the howling of the wind, the brilliancy of the lightning, the glancing of the spray which covered him every moment, these objects, so terrible to an ordinary man, threw him into a kind of mental intoxication, and he has often declared, that this day was the most exquisite of his whole life.

Convinced that the friendship of an eminent man elevates the soul, excites generous emulation, and becomes an additional stimulus to one whose delight is study, and whose most pressing want is an object on which to place his affection, Lamanon anxiously endeavoured to merit the regard of CONDORCET, so well known by his talents, his impieties, his rebellion, and his misfortunes. This academician, justly considering that an apostate priest would be ready to join the conspiracy of the philosophists against the altar and the throne, received Lamanon with distinction, and at length admitted him to his most intimate friendship.

During the three successive years that Lamanon spent at Paris, he followed with care the track of those learned societies, of which he had been elected a member. He became at this period, together with Count de Gebelin, and some other philosophers and artists, one of the founders of the Museum, the greater part of the members of which are now reunited in the open society of sciences, letters, and arts, at Paris. Among the different papers of his that were read at various meetings of these societies, Ponce mentions with particular approbation what he calls *a notice* of Adam de Crapone, an eminent hydraulic engineer; a memoir on the Cretins; a memoir on the theory of the winds; a treatise on the alteration in the course of rivers, particularly the Rhone; and another on an enormous bone belonging

to

Lamanon. to ſome cetaceous fiſh, that was dug up at Paris in laying the foundations of a houſe in the *rue Dauphine*. We have not ſeen theſe memoirs; but as their author was the friend of Condorcet, and fancied that he had attained the ſecrets of creation, we can eaſily conceive their tendency.

Having reſolved again to reviſit Switzerland and Italy, Lamanon firſt went to Turin, where he allied himſelf to the learned of that country. During his ſtay there, the brilliant novelty diſcovered by Montgolfier was occupying the attention of all the philoſophers of Europe. Lamanon, deſirous of making ſome experiments of this kind himſelf, aſcended in a balloon from the city of Turin; but not perceiving in this diſcovery, which had at firſt highly intereſted him, an object of public utility; not foreſeeing, that one day, on the plains of Fleurus, it would be the cauſe of rallying and eſtabliſhing victory under the ſtandards of France, he returned to his favourite occupations. Purſuing his route from Piedmont, he viſited Italy, and returned by Switzerland, where he explored the Alps and aſcended the ſummit of Mont Blanc; thence returning, loaden with the ſpoils of the countries which he had traverſed, to Provence, he employed himſelf in the arrangement of the intereſting fruits of his journey.

Of the ſcrupulous exactneſs of his obſervations, his eulogiſt gives the following inſtance: "Being convinced that the plain of Crau, divided by the channel of the Durance, had formerly been a lake, he wiſhed to be abſolutely aſſured of it. For this purpoſe he collected a ſpecimen of each of the ſtones that are to be found in this vaſt plain; the number of theſe he found to amount to nineteen; then tracing the courſe of the river towards its head, near the frontiers of Savoy, he obſerved, that above each junction of the tributary ſtreams with the Durance, the variety of pebbles diminiſhed. Afterwards aſcending the current of each of theſe ſmaller ſtreams, he diſcovered on their banks the original rock of every pebble that overſpreads the plain of Crau; thus inconteſtably proving, that this plain was anciently a lake formed by the waters of the Durance, and the ſtreams that fall into it. If all philoſophers (ſays our author) would conduct their examinations with equal preciſion, certain hypotheſes, more brilliant than ſolid, would not find ſo many admirers; the charm of imagination, and the graces of ſtyle, would not ſo often encroach upon the impreſcriptible rights of nature and truth."

To citizen Ponce this appears a demonſtration of Lamanon's theory; but we cannot ſay that it does ſo to us. It may be a kind of proof, though not a demonſtration, that in ſome convulſion of nature, ſtones had been rolled from the rock, and the plain of Crau, for a time, overflowed by the Durance; but it ſurely furniſhes no evidence of that plain's having ever been *a permanent lake*. It *may* have been ſo; but ſuch inveſtigations as this will not guard philoſophers againſt the deluſions of favourite hypotheſes.

It was at the time when Lamanon was preparing for the preſs his great work on the *Theory of the Earth*, that the French government conceived the vaſt project of completing the diſcoveries of Captain Cook: the academy of ſciences was entruſted with the care of ſelecting men capable of rectifying our notions of the ſouthern hemiſphere, of improving hydrography, and advancing the progreſs of natural hiſtory. Condorcet, not knowing any one better qualified for this laſt department than Lamanon, wrote to him an invitation to ſhare the danger and glory of this great enterprize. He accepted with eager tranſport a propoſal that fulfilled his higheſt expectations, haſtened to Paris, refuſed in a conference with the miniſter the ſalary that was offered, took a haſty leave of his friends, and departed for Breſt.

Lamanon, Lamp.

On the 1ſt of Auguſt 1785, the armament ſet ſail under the orders of La Perouſe, an experienced commander, whoſe patriotiſm and ſcientific zeal were equal to his courage and good ſenſe, and who had already merited the public confidence. The philoſophers of all Europe were in expectation of thoſe uſeful diſcoveries, the probable fruit of the zeal and talents employed in the expedition. The beginning of the voyage was proſperous. After various delays, and a multitude of obſervations, the two veſſels arrived at the iſland of Maouna, one of the ſouthern Archipelago. The impatient Lamanon, eager to aſſure himſelf of the truth of the publiſhed accounts of that country, debarked with Langle, the ſecond in command. At the moment of their return, the natives, in hopes of booty, which had been excited by the number of preſents that they had received, ſeized upon the boats, and attacked the party. The French were obliged to have recourſe to arms for ſelf defence, and a deſperate combat enſued. Lamanon, Langle, and ten of the two boats crews, fell a ſacrifice to the fury of theſe barbarians.

Thus periſhed Lamanon, a young man ardent in the purſuits of ſcience, to a high degree diſintereſted, and a zealot in what he thought the cauſe of liberty. He refuſed the ſalary which was allotted to him when he was appointed to this unfortunate expedition; for "if I do not feel ſatisfied (ſaid he) on board the veſſel; if my inclination or curioſity lead me to quit the ſhip, — I ſhould be unhappy if any power in the world had acquired the right of preventing me."

According to M. Ponce, Lamanon ſeemed born to bring about a revolution in ſcience: the depth of his ideas, the energy of his character, the ſagacity of his mind, united to that lively curioſity that can draw inſtruction out of any thing, and leaves nothing unexplored, would have led him to the moſt valuable diſcoveries. In perſon he was tall; and to great vivacity and expreſſion of feature added prodigious ſtrength and activity; in a word, Nature formed him with ſuch care, as if ſhe had intended him for one of thoſe few who are deſtined to great exploits. His ſtyle was nervous, often poetical, without loſing ſight of propriety, and the language of ſentiment might frequently be diſcovered in the midſt of ſtrong and ſtriking expreſſions; and if he wanted the exquiſitely dazzling poliſh of diction, he was eminently gifted with the preciſion of logical reaſoning, which commands attention and enforces perſuaſion.

LAMP (see *Encycl.*) is an inſtrument compriſing three articles which demand our attention, viz. the oil, the wick, and the ſupply of air. It is required that the oil ſhould be readily inflammable, without containing any fetid ſubſtance which may prove offenſive, or mucilage, or other matter, to obſtruct the channels of the wick. Mr Nicholſon ſays*, that he knows of no proceſs by which oils can be meliorated for this purpoſe, except that of waſhing with water containing acid or alkali. Either of theſe is ſaid to render the mucilage of animal oils more ſoluble in water; but acid is to be preferred, becauſe

* *Journal* vol. i. n° 2.

because it is less disposed to combine with the oil itself. Perhaps oil might be deprived of all fetid smell in burning, by being made to pass through Collier's filtering apparatus, described under the word FILTER in this *Suppl.*

The office of the wick appears to be chiefly, if not solely, to convey the oil by capillary attraction to the place of combustion. As the oil is consumed and flies off, other oil succeeds, and in this way a continued current of oil and maintenance of the flame are effected. But as the wicks of lamps are commonly formed of combustible matter, it appears to be of some consequence what the nature and structure of this material may be. It is certain that the flame afforded by a wick of rush differs very considerably from that afforded by cotton; though perhaps this difference may, in a great measure, depend on the relative dimensions of each. And if we may judge from the different odour in blowing out a candle of each sort, there is some reason to suspect that the decomposition of the oil is not effected precisely in the same manner in each. We have also some obscure accounts of prepared wicks for lamps, which are stated to possess the property of facilitating the combustion of very impure oils, so that they shall burn for many hours without smoke or smell.

The economical wicks of M. Leger, concerning which a report was presented to the Academy at Paris in 1782 by Condorcet, Lavoisier, and De Milly, were composed of cotton of different sizes and forms, namely, round and flat, according to the use they were intended to serve. They were covered with a fat substance, of a smell not disagreeable, but feebly aromatic. From the trials of these commissaries it was ascertained: 1. That they afforded a clearer flame, with less undulation. 2. That they consumed somewhat less oil; and, 3. That they possessed the remarkable property of affording neither smell nor smoke, however common the oil made use of. When using a lamp with a flat wick, we have ourselves found a piece of clean cotton stocking answer the purpose better than the cotton wicks which are sold in the shops.

The access of air is of the last importance in every process of combustion. When a lamp is fitted up with a very slender wick, the flame is small, and of a brilliant white colour: if the wick be larger, the combustion is less perfect, and the flame is brown: a still larger wick not only exhibits a brown flame, but the lower internal part appears dark, and is occupied by a portion of volatilised matter, which does not become ignited until it has ascended towards the point. When the wick is either very large or very long, part of this matter escapes combustion, and shews itself in the form of coal or smoke. The different intensity of the ignition of flame, according to the greater or less supply of air, is remarkably seen by placing a lamp with a small wick beneath a shade of glass not perfectly closed below, and more or less covered above. While the current of air through the glass shade is perfectly free, the flame is white; but in proportion as the aperture above is diminished, the flame becomes brown, long, wavering, and smoky; it instantly recovers its original whiteness when the opening is again enlarged. The inconvenience of a thick wick has been long since observed, and attempts made to remove it; in some instances, by substituting a number of small wicks instead of a larger; and in others, by making the wick flat instead of cylindrical. The most scientific improvement of this kind, though perhaps less simple than the ordinary purposes of life demand, is the well known lamp of Argand, described in the *Encyclopædia*.

Much has been said of this lamp, and great praise lavished on the inventor. It cannot indeed be denied that it was a very pretty invention, nor have we the slightest wish to detract from the merit of M. Argand; but truth compels us to say, that the same thought had occurred to others as early as to him, and that lamps had been constructed on his principles long before he had published an account of his lamp to the world (A).

Many ingenious men have endeavoured to determine the most economical method of lighting up large halls and workhouses by means of different lamps and candles; and when the expence of tallow and oil is considered, it will be admitted that they could not employ their time in a manner more beneficial to the poor and the industrious. Among others, Count Rumford and M. Hassenfratz have turned their attention to this subject; and the results of their investigations are worthy of notice. To the Count, a method occurred for measuring the relative quantities of light emitted by lamps of different constructions, which is at once simple and accurate. It is as follows:

"Let the two burning lamps, or other lights to be compared, be called A and B; and let them be placed at equal heights upon two light tables, or moveable stands, in a darkened room; let a sheet of clean white paper be equally spread out, and fastened upon the wainscot, or side of the room, at the same height from the floor as the lights; and let the lights be placed over-against this sheet of paper, at the distance of six or eight feet from it, and six or eight feet from each other, in such a manner, that a line drawn from the centre of the paper, perpendicular to its surface, shall bisect the angle formed by lines drawn from the lights to that centre; in which case, considering the sheet of paper as a plane speculum, the one light will be precisely in the line of reflection of the other.

"This may be easily performed, by actually laying a piece of a looking-glass, six or eight inches square, flat upon the paper, in the middle of it; and observing, by means of it, the real lines of reflection of the lights from that plane, removing it afterwards, as soon as the lights are properly arranged. When this is done, a small cylinder of wood, about ¼th of an inch in diameter, and six inches long, must be held in a vertical position, about two or three inches before the centre of the sheet of paper, and in such a manner, that the two shadows of the cylinder, corresponding to the two lights, may be distinctly seen upon the paper.

If these shadows should be found to be of unequal densities, which will almost always be the case, then that light whose corresponding shadow is the densest must be removed farther off, or the other must be brought nearer to the paper, till the densities of the shadows appear to be exactly equal; or, in other words, till the densities of the rays from the two lights are equal *at the surface of the paper*; when, the distances of the lights from

(A) One of these was employed in the college of Glasgow, by the lecturer on chemistry, so long ago as 1766.

from the centre of the paper being measured, the squares of those distances will be to each other as the real intensities of the lights in question at their sources.

If, for example, the weaker light being placed at the distance of four feet from the centre of the paper, it should be found necessary, in order that the shadows may be of the same density, to remove the stronger light to the distance of eight feet from that centre, in that case, the real intensity of the stronger light will be to that of the weaker as 8^2 to 4^2; or as 64 to 16; or 4 to 1; and so for any other distances.

It is well known, that when any quality proceeds from a centre in straight lines in all directions, like the light emitted by a luminous body, its intensity at any given distance from that centre will be as the square of that distance inversely; and hence it is clear, that the intensities of the lights in question, at their sources, must be to each other as the squares of their distances from that given point *where their rays uniting are found to be of equal density.* For, putting x = the intensity of B, if P represents the point where the rays from A and from B meeting are found to be of equal density or strength, and if the distance of A from P be = m, and the distance of B from the same point P = n; then, as the intensity of the light of A at P, is = $\frac{x}{m^2}$, and the intensity of the light of B at the same place = and as it is $\frac{x}{m^2} = \frac{y}{n^2}$ by the supposition, it will be $x : y :: m^2 : n^2$.

That the shadows being of equal density at any given point, the intensities of the illuminating rays must of necessity be equal at that point also, is hence evident, that the total absence of light being perfect blackness, and the shadow corresponding to one of the lights in question being deeper or fainter, according as it is more or less enlightened by the other, when the shadows are equal, the intensities of the illuminating rays must be equal likewise.

In removing the lights, in order to bring the shadows to be of the same density, care must be taken to recede from, or advance towards, the centre of the paper in a straight line, so that the one light may always be found exactly in the line of reflection of the other; otherwise the rays from the different lights falling upon the paper, and consequently upon the shadows, at different angles, will render the experiment fallacious.

When the intensity of one strong light is compared with the intensities of several smaller lights taken together, the smaller lights should be placed in a line perpendicular to a line drawn to the centre of the paper, and as near to each other as possible; and it is likewise necessary to place them at a greater distance from the paper than when only single lights are compared

In all cases, it is absolutely necessary to take the greatest care that the lights compared be properly trimmed, and that they burn clear and equally, otherwise the results of the experiments will be extremely irregular and inconclusive. It is astonishing what a difference there is in the quantities of light emitted by the same candle, when it burns with its greatest brilliancy, and when it has grown dim for want of snuffing. But as this diminution of light is progressive, and as the eye insensibly conform to the quantity of light actually present, it is not always taken notice of by the spectators; it is nevertheless very considerable, in fact, as will be apparent to any one who will take the trouble to make the experiment; and so great is the fluctuation in the quantity of light emitted by burning bodies, lamps, or candles, in all cases, even under the most favourable circumstances, that this is the source of the greatest difficulties which our author met with in determining the relative intensities of lights by the method here proposed.

To ascertain by this method the comparative densities, or intensities, of the light of the moon and of that of a candle, the moon's direct rays must be received upon a plane white surface, at an angle of incidence of about 60°, and the candle placed in the line of the reflection of the moon's rays from this surface; when the shadows of the cylinder, corresponding to the moon's light and to that of the candle, being brought to be of equal density, by removing the candle farther or bringing it nearer to the centre of the white plane, as the occasion may require, the intensity of the moon's light will be equal to that of the candle *at the given distance of the candle from the plane.*

To ascertain the intensity of the light of the heavens, by day or by night, this light must be let into a darkened room through a long tube blackened on the inside, when its intensity may be compared with that of a candle or lamp by the method above described.

The Count, however, has contrived an apparatus for ascertaining the intensity of the sun's light, compared with the light emitted by any artificial illuminator, with much greater accuracy than it can be done by this simple method. That apparatus we shall describe under the title PHOTOMETER in this *Supplement*; and in the mean time we proceed to lay before our readers the results of his experiments as they relate to economy in the production of artificial light.

The brilliancy of Argand's lamp is not only unrivalled, but the invention is in the highest degree ingenious, and the instrument useful for many purposes; but still, to judge of its real merits as an illuminator, it was necessary to know whether it gives more light than another lamp *in proportion to the oil consumed.* This point he determined in the following manner:

[illegible] a lamp [illegible] wick.

Having placed an Argand's lamp, well trimmed, and burning with its greatest brilliancy, before his *photometer*, and over against it a very excellent common lamp, with a riband wick about an inch wide, and which burnt with a clear, bright flame, without the least appearance of smoke, he found the intensities of the light emitted by the two lamps to be to each other as 17956 to 9063; the densities of the shadows being equal when, the Argand's being placed at the distance of 134 inches, the common lamp was placed at the distance of 95,2 inches, from the field of the photometer.

Both lamps having been very exactly weighed when they were lighted, they were now (without being removed from their places before the photometer) caused to burn with the same brilliancy just 30 minutes; they were then extinguished and weighed again, and were found to have consumed of oil, the Argand's lamp $\frac{213}{1152}$, and the common lamp $\frac{81}{1152}$, of a Bavarian pound.

Now, as the quantity of light produced by the Argand's

gand's lamp, in this experiment, is to the quantity produced by the common lamp as 17956 to 9063, or as 187 to 100, while the quantity of oil consumed by the former is to that consumed by the latter only in the ratio of 253 to 163, or as 155 to 100, it is evident that the quantity of light produced by the combustion of a given quantity of oil in an Argand's lamp is greater than that produced by burning the same quantity in a common lamp, in the ratio of 187 to 155, or as 100 to 85.

The saving, therefore, of oil which arises from making use of an Argand's lamp instead of a common lamp, in the production of light, is evident; and it appears, from this experiment, that that saving cannot amount to less than fifteen *per cent*. How far the advantage of this saving may, under certain circumstances, be counterbalanced by inconveniences that may attend the making use of this improved lamp, our author does not pretend to determine.

Of the relative quantities of light emitted by an Argand's lamp and by a common wax

The Count made a considerable number of experiments to determine the relative quantities of light emitted by an Argand's lamp and a common wax candle; and the general result of them is, that a common Argand's lamp, burning with its usual brightness, gives about as much light as nine good wax-candles; but the sizes and qualities of candles are so various, and the light produced by the same candle so fluctuating, that it is very difficult to ascertain, with any kind of precision, what a common wax-candle is, or how much light it ought to give. He once found that his Argand's lamp, when it was burning with its greatest brilliancy, gave twelve times as much light as a good wax candle $\frac{3}{4}$ths of an inch in diameter, but never more.

Of the fluctuations of the light emitted by candles.

To determine to what the ordinary variations in the quantity of light emitted by a common wax candle might amount, he took such a candle, and, lighting it, placed it before the photometer, and over against it an Argand's lamp, which was burning with a very steady flame; and measuring the intensity of the light emitted by the candle from time to time, during an hour, the candle being occasionally snuffed when it appeared to stand in need of it, its light was found to vary from 100 to about 60. The light of a wax-candle of an inferior quality was still more unequal; but even this was but trifling, compared to the inequalities of the light of a tallow candle.

An ordinary tallow-candle, of rather an inferior quality, having been just snuffed, and burning with its greatest brilliancy, its light was as 100; in eleven minutes it was but 39; after eight minutes more had elapsed, its light was reduced to 23; and in ten minutes more, or twenty-nine minutes after it had been last snuffed, its light was reduced to 16. Upon being again snuffed, it recovered its original brilliancy, 100.

4 Of the relative quantities of bees-wax, tallow, olive-oil, rape-oil, and linseed-oil, consumed in the production of light.

In order to ascertain the relative quantities of bees wax and of olive-oil consumed, in the production of light, the Count proceeded in the following manner: Having provided an end of a wax-candle of the best quality, ,68 of an inch in diameter, and about four inches in length, and a lamp with five small wicks, which he had found upon trial to give the same quantity of light as the candle, he weighed very exactly the candle and the lamp filled with oil, and then, placing them at equal distances (forty inches) before the field of the photometer, he lighted them both at the same time; and, after having caused them to burn with precisely the same degree of brightness *just one complete hour*, he extinguished them both, and, weighing them a second time, he found that 100 parts of wax and 129 parts of oil had been consumed.

Hence it appears, that the consumption of bees wax is to the consumption of olive-oil, in the production of the same given quantity of light, as 100 is to 129.

In this experiment no circumstance was neglected that could tend to render the result of it conclusive; care was taken to snuff the candle very often with a pair of sharp scissars, in order to make it burn constantly with the same degree of brilliancy; and the light of the lamp was, during the whole time, kept in the most exact equilibrium with the light of the candle, which was easily done by occasionally drawing out a little more or less, one or more of its five equal wicks. These wicks, which were placed in a right line, perpendicular to a line drawn from the middle wick to the middle of the field of the photometer, were about $\frac{1}{10}$th of an inch in diameter each, and $\frac{1}{4}$th of an inch from each other; and, when they were lighted, their flames united into one broad, thin, and very clear, white flame, without the least appearance of smoke.

In order to ascertain the relative consumption of olive-oil and rape-oil, in the production of light, two lamps, like that just described, were made use of; and, the experiment being made with all possible care, the consumption of olive-oil appeared to be to that of rape-oil, in the production of the same quantity of light, as 129 is to 125.

The experiment being afterwards repeated with olive-oil and very pure linseed-oil, the consumption of olive-oil appeared to be to that of linseed oil as 129 to 120.

The experiment being twice made with olive oil and with a tallow candle; once when the candle, by being often snuffed, was made to burn constantly with the greatest possible brilliancy, and once when it was suffered to burn the whole time with a very dim light, owing to the want of snuffing; the results of these experiments were very remarkable.

When the candle burnt with a clear, bright flame, the consumption of the olive oil was to the consumption of the tallow as 129 is to 101; but when the candle burnt with a dim light, the consumption of the olive-oil was to the consumption of the tallow as 129 is to 229. So that it appeared, from this last experiment, that the tallow, instead of being nearly as productive of light in its combustion as bees wax, as it appeared to be when the candle was kept constantly well snuffed, was now, when the candle was suffered to burn with a dim light, by far less so than oil.

But this is not all; what is still more extraordinary is, that the very same candle, burning with a long wick, and a dim light, actually consumed *more tallow* than when, being properly snuffed, it burnt with a clear, bright flame, and gave near *three times as much light*.

To be enabled to judge of the relative quantities of light actually produced by the candle in the two experiments, it will suffice to know, that in order to counterbalance this light at the field of the *photometer*, it required, in the former experiment, the consumption of 141 parts, but in the latter only the consumption of 64 parts, of olive-oil. But in the former experiment 110,

and

and in the latter 114, parts of tallow were actually found to be consumed. These parts were 8192ths of a Bavarian pound.

From the results of all the foregoing experiments, it appears that the relative expence of the undermentioned inflammable substances, in the production of light, is as follows:

		Equal Parts in Weight.
Bees wax.	A good wax-candle, kept well snuffed, and burning with a clear, bright flame, - - -	100
Tallow.	A good tallow candle, kept well snuffed, and burning with a bright flame, - - - - -	101
	The same tallow-candle, burning very dim for want of snuffing,	229
Olive-oil.	Burnt in an Argand's lamp, - -	110
	The same burnt in a common lamp, with a clear, bright flame, without smoke, - - - - -	129
Rape-oil.	Burnt in the same manner, - - -	125
Linseed-oil.	Likewise burnt in the same manner, - - - - - -	120

With the foregoing table, and the prices current of the therein mentioned articles, the relative prices of light produced by those different materials may very readily be computed.

In the year 1795, Mr J. H. Hassenfratz was employed by the French government to make a series of experiments to determine the most economical method of procuring light from the different combustible substances usually employed for that purpose. The materials of his experiments were, wax, spermaceti, and tallow candles, fish-oil, oil of coleseed, and of poppy seeds. In using these oils both the Argand and common lamps were employed. The wicks of the latter were round, containing thirty-six cotton threads. The tallow and spermaceti candles were mould, six to the pound. The wax candles five to the pound. Mr Hassenfratz used the same method with Count Rumford for determining the comparative intensity of the lights.

Count Rumford, as we have seen, used the Argand lamp as a standard for comparison; but as the intensity of its light varies according to the height of the wick, Mr Hassenfratz preferred a wax-candle, making use of it soon after it was lighted. When two luminous bodies, of different intensities, are put in comparison with each other, the shadows are of two colours. That from the weakest light is blue, and from the strongest, red. When the lights of two different combustible bodies are compared, they are either red or blue in a compound ratio of the colour and intensity. Thus in comparing the shadows from different luminous bodies, they will be red or blue respectively, in the following order:

Light of the sun.
——- of the moon.
——- of Argand lamps.
——- of tallow-candles.
——- of wax ditto.
——- of spermaceti ditto.
——- of common lamps.

That is to say, when a body is illuminated by the sun and by any other luminous substance, the shadow of the former is red, and of the latter, blue. In like manner, the shadow from an Argand lamp is red, when placed by that of a tallow candle, which is blue.

The following table will shew, according to Mr Hassenfratz, the proportional distance that different luminous bodies should be placed at to produce an equally intense shadow from the same object. The second column gives the proportional intensity of each light, which is known to be in proportion to the squares of the distances of luminous bodies giving the same depth of shadow. The third column shews the quantity of combustible matter consumed in the hour by each mode of giving light, which Mr Hassenfratz calculates from the average of many repeated experiments.

		Distance.	Intensity.	Quantity consumed per hour	Quantity equired for equal intensities.
Argand lamps with	Oil of poppy seed	10	10.000	23	23
	— of fishes	10	10 000	23.77	23.77
	— of cole-seed	9.246	8 549	14.15	16.59
Common lamps with	Oil of cole-seed	6.774	4.588	8.81	19.2
	— of fishes	6.524	4.550	9.14	20.06
	— of poppy-seed	5.917	3.501	7 0	20.14
	Spermaceti candle	5.917	3 501	9.23	
	Old tallow candle	5 473	2.995	7.54	25.17
	New ditto	5.473	2 995	8 .3	27.48
	Wax candle	4.275	1 877	9 54	

The relative quantity of combustible matter required to produce *equal* lights at equal distances, may be obtained by a simple rule of proportion from the above data. Thus, if a given intensity of light, expressed by 3.501, has been produced by a consumption of 9.23 of spermaceti in the hour, the same luminous body will produce a light of 10.000, by consuming in the same time a quantity of spermaceti $= \frac{10.000 \times 9.23}{3.501} = 26.37$.— Therefore we may add to the table a fourth column, expressing the quantity of combustible which each body must consume to produce a light of 10.000.

From what has been laid down, it will also appear that the number of lights required to produce a given light, will be as follows: To produce a light equal to 100 Argand lamps, burning poppy-seed oil, it will require

100 Argand lamps with fish-oil
117 Ditto do. with cole seed oil
218 Common lamps with cole-seed oil
219 Ditto do. with fish-oil
285 Ditto do. with poppy seed oil
285 Spermaceti candles
333 Tallow ditto
546 Wax ditto.

Mr Hassenfratz next takes notice of the comparative price of these articles; by which he finds, that in Paris the most expensive light is that produced from wax-candles; and the most *economical*, that from oil of cole-seed, burned in Argand lamps.

The chief difference between the Argand and com-

mon lamp is, that in the latter much of the oil is volatilized without combustion, and hence the unpleasant smell which it produces; whereas in the former, the heat is so great at the top of the wick, that all the oil is decomposed in passing through, the disposition of the wick allowing the free access of air to assist combustion. It should therefore follow, that the Argand lamp consumes less fuel to produce a given light than the common lamp, and this, as we have seen, is the opinion of Count Rumford. Yet (Mr Hassenfratz observes) there are two circumstances that prevent the full effect of the complete combustion in the Argand lamp. The one is, that the glass cylinder absorbs a part of the rays of light as they pass through; the other, that the column of light proceeding from the inner surface of the wick, is, in part, lost, by being obliged to pass through that from the outer surface. Count Rumford allows the first cause of diminution of light, and estimates it at .1854, but not the latter. The author of this memoir, in repeating Count Rumford's experiments, asserts, that when two candles are placed so that the light of the one is obliged to pass through that of the other, the sum of the light so produced is not so strong as when they are placed side by side; for in the first case, a part of the hindmost light is absorbed by the foremost.

LANCASHIRE. In the account which we have given of that county in the *Encyclopædia*, an obliging correspondent has pointed out to us some mistakes. He assures us, that the sea coast, where we understood the atmosphere to be loaded with such exhalations as produce malignant and intermitting fevers, is remarkably healthy; and he speaks from experience, having lived on that coast for forty years. He assures us likewise, that the Duke of Bridgewater's inland navigation was begun soon after, if not before, the year 1736, and that he (the writer), so early as 1764, was one of a party who sailed up the sough or edit a considerable way to see how the coals were worked. The same correspondent has pointed out a few mistakes in our account of

LANCASTER, the capital of the county. "That town (he says) carries on no trade whatever with North America, but a very considerable one with Jamaica and the other West India islands, in vessels of from 100 to 300 tons burthen. It exports to these islands all such British manufactures as they have occasion for, Irish linens, and salted provisions of all kinds, such as Irish beef, pork, butter, &c. It trades also to the Baltic, Portugal, Hamburgh, &c. to a large amount; and some of its ships with their cargoes have of late been worth from L. 60 to L. 80,000 sterling. It has, however, no communication by water with the rivers Mersey, Dee, &c. as we have said; the canal reaching as yet no farther than to near Preston in Lancashire." The communication with these rivers is indeed intended to be completed; but whether the scheme be practicable is, according to our correspondent, very uncertain.

LANTERN (See *Encycl.*). Sir George Staunton informs us, that of the Chinese lanterns, some were such as we have described, viz. composed of thin silk gauze, painted or wrought in needle-work with figures of birds, insects, flowers, or fruit, and stretched on neat frames of wood. Others, however, were very different, being entirely made of horn. These were so thin and transparent, that they were taken at first for glass; a material to which, for this purpose, the horn is preferred by the Chinese, as cheaper, lighter, less liable to accident, and, in case of accident, more easily repaired; many of them were about two feet in the diameter, and in the form of a cylinder, with the ends rounded off, and the edges meeting in the point to which the suspending cords were tied. Each lantern consisted of an uniform piece of horn, the joints, or seams, being rendered invisible by an art found out by the Chinese; among whom, the vast number of such lanterns used in their dwelling houses and temples, as well as on the occasions of their festivals and processions, have led to many trials for improving their construction. The horns generally employed are those of sheep and goats. The usual method of managing them, according to the information obtained upon the spot, is to bend them by immersion in boiling water, after which they are cut open and flattened; they then easily scale, or are separated into two or three thin laminæ or plates. In order that these plates should be made to join, they are exposed to the penetrating effect of steam, by which they are rendered almost perfectly soft. In this state the edges of the pieces to be joined are carefully scraped and slanted off, so as that the pieces overlapping each other shall not together exceed the thickness of the plate in any other part. By applying the edges, thus prepared, immediately to each other, and pressing them with pincers, they intimately adhere, and incorporating, form one substance, similar in every respect to the other parts; and thus uniform pieces of horn may be prepared to almost any extent. It is a contrivance little known elsewhere, however simple the process appears to be; and perhaps some minute precautions are omitted in the general description, which may be essential to its complete success.

Such lanterns as these would be very proper for military store houses; and Rochon of *the National Institute* was employed, since the commencement of the present war, to make them, if he could, for the marine storehouses of France. While he was thus engaged, however, it occurred to him, that he might supply the pressing wants of the navy without horn, merely by filling up the interstices of wire-cloth with fine transparent glue. In carrying this thought into execution, he at first tinned the iron wires of the sieve cloth he made use of; but afterwards found it more convenient, in every respect, to give it a slight coating of oil paint to preserve it from rust. The glue he made use of was afforded by boiling the clippings of parchment with the air-bladders and membranes of sea fish; materials which he used, not from any notion that they were preferable to isinglass, but because they were the cheapest he could procure. He added the juice of garlic and cyder to his composition, in such proportions as he found to communicate great tenacity, and somewhat more of transparence than it would have possessed without them. Into this transparent and very pure glue or size he plunged his wire cloth, which came out with its interstices filled with the compound. It is requisite that the size should possess a determinate heat and consistence, concerning which experience alone must guide the operator.

When this prepared wire cloth is fixed in the lantern, it must be defended from moisture by a coating of pure drying linseed oil; but even in this state it is not fit to be exposed to the weather. The ease with which these lanterns are repaired in case of accident, by a

slight

flight coating of glue, is pointed out as a great advantage by the inventor; who likewise informs us, that they were used in the expedition to Ireland as signal lanterns, though contrary to his wishes.

LAPIS FUNGIFER, a species of earth found near Rome, Naples, and Florence, of which the following account is taken from the *New Transactions of the Royal Academy of Sciences at Stockholm* for the year 1797: Near Naples the lapis fungifer is found in the chalk-hills like a white stalactites, intermixed with a great many fine roots of shrubs; and near Florence there is a species of it, consisting of hardened turf, which is dug up near volcanoes. The author made experiments with a piece procured from Italy, and found that 100 parts contain from 45 to 46 siliceous earth, 23 argillaceous earth, 7 calcareous earth, and 20 calx of iron, with some white magnesia and vegetable alkali. It is well known, that when this friable species of stone is preserved in cellars and moistened with water, it produces abundance of eatable mushrooms, which in Italy are highly esteemed and brought to the first tables. Hence the origin of its name.

LARDIZABALA, a new genus of plants belonging to the *diœcia hexandria* of Linnæus. It is a native of Chili, and is thus described in Perouse's Voyage, from drawings sent to France by La Martiniere. The leaves are alternate, on footstalks inflated at their base. Each leaf is bi-ternate, that is to say, it is divided into three leaflets, each of which is again subdivided into three oval sharp-pointed folioles, which, when young, are entire, but afterwards become obscurely lobed. The flowers, disposed in simple and pendent clusters, grow towards the top of the stem and of the branches in the axillæ of the leaves. The plant is diœcius. At the base of each cluster of blossoms are two small, rounded, oval, floral leaves.

MALE FLOWER.—*Calyx* formed of six expanding leaves, oblong oval, and obtuse, of which the three outermost are the largest. *Corolla* composed of six sharp lanceolated petals, opposite to, and shorter than, the leaves of the calyx. A cylinder rises from the centre of the flower of the length of the petals, terminated by six oblong bilocular anthers, which open from below.

FEMALE FLOWER.—*Calyx*, similar to that of the male flower, but larger. *Corolla* inserted beneath the pistil, composed of six petals, rarely entire, but generally bifid or trifid at their summit: shorter than the leaves of the calyx. *Stamina* six, having the same insertion as the corolla; filaments distinct, broad, very short, surrounding the pistil; *anthers*, six, upright, oblong, acuminated, barren. *Seed bud*, cells, from three to six, oblong, gibbous on the outside, of nearly the length of the corolla; styles none; stigmata, sitting, oblong, permanent. *Berries*, equal in number to the cells, oblong, acuminated (divided into six cells, containing several angular seeds. *Flora Peruviana*).

The general character of the lardizabala evidently places this new genus among the family of the *menispermæ*, to which it is related by its climbing stalk, its bunches of diœcious flowers, by its six petals, stamina, and leaves of its calyx, by its pistil, composed of from three to six cells, which contain as many seeds. It differs from the known genera of this order only in its fruit, which, instead of being monospermous, contains several seeds. This character, which requires the introduction of a new section into the *menispermæ*, strengthens the relation of this family to the next order of the *anonæ*. In fact, the greater part of the genera of the anonæ, as they have in the same flower several fruits, with numerous seeds, differ in this particular from all the genera of the menispermæ; and by placing between them the lardizabala, we establish a natural transition. In order to confirm these resemblances, it only remains to examine the inside of the fruit, and particularly the structure of the seeds. Those of the menispermæ are reniform, at least on the inside, inclosed in a hinged pericarpium, and containing in their upper part a very small dicotyledonous embryo. The characters that we have given of the lardizabala render probable a similar structure in its seeds.

LARMIER, in architecture, a flat square member of the cornice below the cimasium, and jets out farthest; being so called from its use, which is to disperse the water, and cause it to fall at a distance from the wall, drop by drop, or, as it were, by tears; *larme* in French signifying a tear.

LATUS PRIMARIUM, a right line drawn through the vertex of the section of a cone, within the same, and parallel to the base.

Latus Rectum. See *Conic Section*, Encycl.

Latus Transversum of the hyperbola, is the right line between the vertices of the two opposite sections, or that part of their common axis lying between the two opposite cones.

LAVA. In addition to the observations of Sir William Hamilton, Bergmann, Formes, and Dalmieu, on the composition of different lavas, which have been given in the *Encyclopædia*, we cannot refuse ourselves the pleasure of noticing, in this place, those of Sir James Hall. From a number of well-devised experiments, Sir James thinks himself warranted to conclude, that lava and whinstone are intrinsically the same substance; and that their apparent differences arise wholly from the circumstances under which they have passed from a liquid to a solid state. The lavas, it is well known, have been cooled rapidly in the open air, and the whins (according to Dr Hutton's theory, which Sir James seems willing to adopt) slowly in the bowels of the earth.

Though we are far from adopting that theory in all its parts, to which we think insuperable objections may be made (see EARTH, *Encycl.* n° 120), we admit, that the experiments of Sir James Hall go far to establish the identity of lava and whinstone. These experiments were made upon seven different species of whin and six lavas, of which four were broken from the rents of Etna and Vesuvius by Sir James himself. I of the original whinstones was reduced, by fusion and subsequent rapid cooling, to a state of perfect glass. This glass, being again placed in the furnace, was subjected to a second fusion. The heat, being then reduced to a temperature generally about 28° of Wedgewood, was maintained stationary for some hours; when the crucible was either immediately removed, or allowed to cool with the furnace. The consequence was, that in every case the substance had lost the character of glass, and by crystallization had assumed in all respects that of an original whinstone. It must be owned, that in most cases the new production did not exactly resemble the particular original from which it was formed,

Lava, Lavoisier.

ed, but some other original of the same class; owing to accidental varieties in the mode of refrigeration, and to chemical changes which unavoidably took place during the process. In the case, however, of the rock of Edinburgh castle, and of that of the basaltic columns of Staffa, the artificial substances bear a complete resemblance to their originals, both in colour and texture.

The lavas were now treated in the same way, and were each, by fusion and rapid cooling, reduced, as the whinstones had been, to glass. This glass, when fused again and cooled slowly, yielded the same kind of crystallized, stony, or earthy masses, completely resembling an original whin or lava.

Although the internal structure of lava was thus accounted for, yet Sir James was embarrassed with the state of its external surface; which, though cooled in contact with the open air, is seldom or never vitreous, holding an intermediate station between glass and stone; but this difficulty was removed by a circumstance which took place in the course of these experiments. It was found, that a small piece of glass of any of the lavas, or of several of the whins, being introduced into a muffle, the temperature of which was at any point between the 20th and the 22d degree of Wedgewood's scale, the glass became quite soft in the space of one minute; but, being allowed to remain till the end of a second minute, it was found to have become hard throughout in consequence of a rapid crystallization, to have lost its character of glass, and to have become by 12 or 14 degrees more infusible, being unaffected by any heat under 30, though the glass had been fusible at 18° or at 16°. This accounted for the scoria on the surface of lavas; for the substance even at the surface, being in contact with the flowing stream, and surrounded with heated air, could not cool with excessive rapidity; and the experiment shews, that should any part of the mass, in descending heat, employ more than one or two minutes in cooling from 22 to 20, it would infallibly lose its vitreous character.

Independently of any allusion to system or to general theory, Sir James Hall flatters himself that these experiments may be of some importance, by simplifying the history of volcanoes; and, above all, by superseding some very extraordinary, and, he conceives, unphilosophical opinions advanced with regard to volcanic heat, which has been stated as possessing very little intensity, and as acting by some occult and inconceivable influence, or with the help of some invisible agent, so as to produce liquidity without fusion. These suppositions, which have been maintained seriously by some of the most celebrated naturalists in Europe, have originated from the difficulty of accounting for the stony character of lavas when compared with that of glass, which they assume in consequence of fusion in our furnaces. But now he hopes we may be relieved from the necessity of such violent efforts of imagination, since the phenomena have been fully accounted for by the simple, though unnoticed, principle of refrigeration, and have been repeated again and again with ease and certainty in a small chamber furnace.

LAVOISIER (Antoine Laurent), was born in Paris on the 26th of August 1743. His father, who directed his education, was opulent, and spared no cost for his improvement. The youth shewed a decided taste for the physical sciences. In 1764, government having proposed an extraordinary premium for the best and cheapest mode of lighting the streets of a large city, Lavoisier obtained the gold medal; and his memoir, full of nice investigation, was printed by the Academy. Into that body he was received on the 13th May 1768, in spite of a formidable opposition; and to its service he ever after devoted his labours, and became one of its most useful associates and coadjutors.

His attention was successively occupied with every branch of physical and mathematical science. The pretended conversion of water into earth, the analysis of gypsum in the neighbourhood of Paris, the crystallization of salts, the effects produced by the *grande de loupe* of the garden of the Infanta, the project of bringing water from l'Yvette to Paris, the congelation of water, and the phenomena of thunder and the aurora borealis—all occupied his attention.

Journeys, undertaken in concert with Guettard into every district of France, enabled him to procure numberless materials towards a description of the lithological and mineralogical empire; these he arranged into a kind of chart, which wanted little of being completed. They served also as a foundation for a more laborious work of his on the revolutions of the globe, and the formation of *Couches de la Terre*; a work of which two beautiful sketches are to be seen in the Memoirs of the French Academy for 1772 and 1787. All the fortune and all the time of Lavoisier were devoted to the culture of the sciences; nor did he seem to have a preponderating inclination for any one in particular, until an event, such as seldom occurs in the annals of the human mind, decided his choice, and attached him thenceforth exclusively to chemistry—a pursuit which has since rendered his name immortal.

The important discovery of gases was just announced to the philosophical world. Black, Priestley, Scheele, Cavendish, and Macbride, had opened to physiologists a sort of new creation; they had commenced a new era in the annals of genius, which was to become equally memorable with those of the compass, printing, electricity, &c.

It was about the year 1770 that Lavoisier, struck with the importance and grandeur of this discovery, turned his attention to this inexhaustible fountain of truths, and instantly perceived, by a kind of instinct, the glorious career which lay before him, and the influence which this new science would necessarily have over the whole train of physical researches. Of those who had preceded him, the most indefatigable experimenter was Priestley; but facts the most brilliant remained frequently unproductive in his hands; on every occasion he was ready to frame some crude hypothesis, which as hastily he abandoned. Lavoisier was imbued with the true spirit of inductive philosophy; his observations, eminently precise and luminous, always pointed to general views. In 1774, he published his chemical opuscules, which contained a very neat history of all that had been done with respect to gases, and concluded with the author's capital experiments, by which it was proved, that metals, in calcination, derive their augmentation of weight from the absorption of air. Soon afterward, he shewed, in opposition to Priestley, that nitrous acid is composed of air; a remark, of which the importance appeared in the sequel. His ingenuity as a chemist was now so well known, that in 1776 Turgot employed

ed him to inspect the manufacture of gun-powder. He introduced some valuable improvements, and, suppressing the odious visits in quest of the materials of saltpetre, he yet quintupled its produce. The gun powder would now carry 120 toises, when formerly it would not reach 90. This superiority was indeed acknowledged in the last war.

It had been alleged, that by frequent distillation water is converted into earth. This question Lavoisier resolved in 1778, having shewn that the earthy sediment was owing to the continual erosion of the internal surface of the retort. In that same year he made a more interesting discovery; namely, that the respirable portion of the atmosphere is a constituent principle of all acids, and which he therefore denominated *oxygen*; a most important fact, and the first great step towards the new chemistry, which the composition of water, ascertained in 1783, triumphantly completed.

Lavoisier possessed decisive advantages over his contemporaries; he studied a geometrical accuracy of investigation; and his wealth enabled him to make experiments on a large scale, and to use instruments of the most perfect construction. He was able to hold in his house, twice every week, assemblies, to which he invited every literary character that was most celebrated in geometrical, physical, and chemical, studies; in these instructive *conversaziones*, discussions, not unlike such as preceded the first establishment of academies, regularly took place. Here the opinions of the most eminent literati in Europe were canvassed; passages the most striking and novel, out of foreign writers, were recited and animadverted on; and theories were compared with experiments. Here learned men of all nations found easy admission; Priestley, Fontana, Blagden, Ingenhousz, Landriani, Jacquin, Watt, Bolton, and other illustrious physiologists and chemists of England, Germany, and Italy, found themselves mixed in the same company with La Place, La Grange, Borda, Cousin, Meunier, Vandermonde, Monge, Morveau, and Berthollet. Happy hours passed in these learned interviews, wherein no subject was left uninvestigated that could possibly contribute to the progress of the sciences, and the amelioration and happiness of man. One of the greatest benefits resulting from these assemblages, and the influence of which was soon afterwards felt in the academy itself, and consequently in all the physical and chemical works that have been published for the last twenty years in France, was the agreement established in the methods of reasoning between the natural philosophers and the geometricians. The precision, the severity of style, the philosophical method of the latter, was insensibly transfused into the minds of the former; the philosophers became disciplined in the tactics of the geometricians, and were gradually moulded into their resemblance.

It was in the assemblage of these talents that Lavoisier embellished and improved his own. When any new result from some important experiment presented itself, a result which threatened to influence the whole theory of the science, or which contradicted theories till then adopted, he repeated it before this select society. Many times successively he invited the severest objections of his critical friends; and it was not till after he had surmounted their objections, to the conviction and entire persuasion of the society; it was not till after he had removed from it all mystery and obscurity, that he ventured to announce to the world any discovery of his own.

At length he combined his philosophical views into a consistent body, which he published in 1789, under the title of *Elements of Chemistry*; a book which is a most beautiful model of scientific composition, clear, logical, and elegant. It would be foreign to our purpose to attempt an exposition of the principles, or to expatiate on the merits, of this celebrated system; which, within the space of a very few years, has been almost universally adopted; and which, if not the genuine interpretation of nature, approaches as near to it as the present state of knowledge will permit. See CHEMISTRY in this *Supplement*.

The last, but not the least useful, of Lavoisier's philosophical researches, on the Perspiration of Animals, was read to the Academy on the 4th May 1791, and of which part was published in the volume for 1790. He found, by some delicate experiments, made in conjunction with Segnin, that a man in 24 hours perspires 45 ounces; that he consumes 33 ounces of vital air; that he discharges from the lungs 8 cubic feet of carbonic acid gas, of which one-third is carbon and two-thirds are oxygen; that the weight of water discharged from the lungs amounts to 23 ounces, of which 3 are hydrogen and 20 oxygen, exclusive of 6 ounces of water already formed, lost in pulmonary perspiration. These discoveries were directed to the improvement of medicine.

We have mentioned the assistance which Lavoisier received while he was digesting his new system of chemistry; but we must add, that to him pertains exclusively the honour of a founder. His own genius was his sole conductor, and the talents of his associates were chiefly useful in illustrating discoveries he himself had made; he first traced the plan of the revolution he had been a long time conceiving; and his colleagues had only to pursue and execute his ideas.

In the twenty volumes of the Academy of Sciences, from 1772 to 1793, are 40 memoirs of Lavoisier, replete with all the grand phenomena of the science; the doctrine of combustion, general and particular; the nature and analysis of atmospherical air; the formation and fixation of elastic fluids; the properties of the matter of heat; the composition of acids; the augmentation of the ponderosity of burnt bodies; the decomposition and recomposition of water; the dissolution of metals; vegetation, fermentation, and animalization. For more than 15 years consecutive, Lavoisier pursued, with unshaken constancy, the route he had marked out for himself, without making a single false step, or suffering his ardour to be damped by the numerous and increasing obstacles which constantly beset him.

Many were the services rendered by Lavoisier, in a public and private capacity, to manufactures, to the sciences, and to artists. He was treasurer to the Academy after Buffon and Tillet, and introduced economy and order into the accounts. He was also a member of the Board of Consultation, and took an active share in whatever was going forwards. When the new system of measures was agitated, and it was proposed to determine a degree of the meridian, he made accurate experiments on the expansion of metals, and constructed a metalline thermometer. By the National Conven-

tion he was consulted on the means of improving the manufacture of assignats, and of increasing the difficulties of forging them.

Like a good citizen, Lavoifier turned his thoughts to political economy. Between the years 1778 and 1785, he allotted 240 *arpents* in the Vendômois to experimental agriculture, and increased the usual produce by one-half. In 1791, he was invited by the Constituent Assembly to digest a plan for simplifying the collection of the taxes. This gave occasion to an excellent report, afterwards printed with the title of *Territorial Riches of France*. At this time, also, he was appointed commissioner of the national treasury, in which he effected some beneficial reforms.

During the horrors of the Robespierrean dictatorship, Lavoisier told La Lande that he foresaw he should be stripped of his property, but that he would work for his bread. The profession of apothecary would have suited him the best. But his doom was already fixed. On the 8th of May 1794, confounded with 28 farmers general, he suffered on the scaffold, merely because he was rich!

Lavoifier was tall, and of a graceful, sprightly appearance. He was mild, sociable, obliging, and extremely active; and in his manners he was unaffectedly plain and simple. Many young men, not blessed with the gifts of fortune, but incited by their genius to woo the sciences, have confessed their obligations to him for pecuniary aid; many, also, were the unfortunate whom he relieved in silence, and without the ostentation of virtue. In the communes of the department of the *Loir* and *Char*, where he possessed considerable estates, he would frequently visit the cottages of indigence and distress; and long will his memory be cherished there. But his reputation, influence, virtues, and wealth, gave him a great preponderance, which unfortunately provoked the jealousy of a crew of homicides, who made a sport of sacrificing the lives of the best of men to a sanguinary idol.

This great and good man married, in 1771, Marie-Anni-Pierette Paulze, daughter of a farmer-general; a woman whose wit and accomplishments constituted the charm of his life; who assisted him in his labours, and even engraved the figures of his last work.

LEAD. See that article (*Encycl.*), and CHEMISTRY-*Index* in this *Supplement*. It is well known, that lead generally contains a portion of silver, and sometimes of gold; and that there are occasions, particularly in assaying, when it is of importance to have it freed from these metals. For accomplishing these purposes different processes have been proposed; but the following by Pet. Jac. Hjelm, as it is the least expensive, promises to be the most useful.

LITHARGE (see *Encycl.*) was the substance on which this chemist made his experiments, and his principal object was to free it from all mixture of silver. This was accomplished in the following manner: He placed a crucible, in which half a pound of litharge found good room, and which was fitted with a close cover, in a wind-furnace filled with dead coals. He then put into the crucible a mixture of four ounces of potash and the same quantity of powder of flint. When the whole was well melted by strengthening the draught, and making the coals glow, he took off the cover, and laid hold of the crucible with a pair of tongs, in order to take it out, and to suffer this very fusible glass to cover the inside of the crucible, to secure it from the glass of the lead which he meant to melt in it. The superfluous glass was poured out; the crucible again placed on its foot, and half a pound of litharge thrown into it with a shovel. The cover was placed upon it while the litharge was melting; and when it was thoroughly glowing and fluid, charcoal dust was sifted into the uncovered crucible through a sieve, so that the surface of the litharge was completely covered with it. This immediately produced an effervescence, and the rising of bubbles, by means of the separation of the air occasioned by the reduction of the lead. During this process, the cover was put on, and a few coals thrown into the furnace; when these were burnt, every thing in the crucible was quiet, and the melted mass was poured into a warm conical mould. The crucible was then again filled with half a pound of the same kind of litharge, and put into the furnace, and charcoal dust was several times sifted over the melted surface, till it was well covered before the mass was thrown out, a sufficient space being every time left for the effervescence. The first mass had, in the mean time, become cool, and, on examination, contained four ounces of lead at the bottom, and litharge at the top. When this litharge was reduced with potashes and wine-stone, the lead thence obtained, which weighed 2½ ounces, was found to contain less than one-half grain of silver in the pound. In the second mass there was found somewhat more than six ounces of lead, which contained all the silver that had been before mixed with the litharge, because in the lead which had been reduced from the litharge in the above manner, there were no perceptible traces of silver. This lead was then melted over a slow fire, and cast into bars, which were rolled smooth, and formed into masses of a known weight, to be used for assaying gold and silver, and for other purposes of the same kind. All these meltings were made in one crucible, which, according to every appearance, remained unhurt. If the same experiments were made with red lead, the like result would infallibly follow.

With the same view of obtaining lead free from silver, he melted, in the like manner, half a pound of white lead, which produced half an ounce of lead. When the litharge standing over it was revived, the lead obtained was still found to contain too much silver. He therefore precipitated another half pound of white lead by charcoal powder, after the lead that fell from it had been separated; and then it produced, by reviving, a mass of lead without any mixture of silver.

LEDYARD (——.——), the celebrated, though unfortunate, traveller, was a native of North America, but of what province we have not learned. We are equally ignorant of the year of his birth, and the rank of his parents; but have no reason to think that they were opulent. From his early youth he displayed a strong propensity to visit unknown and savage countries; and to gratify that propensity, he lived for several years with the American Indians, whose manners and habits he seemed in some degree to have acquired. Afterwards he sailed round the world with Captain Cook in the humble station of a corporal of marines; and on his return, he determined to traverse the vast continent of America, from the Pacific to the Atlantic Ocean.

This design being frustrated by his not obtaining a

passage

Ledyard.

passage to Nootka Sound, he determined to travel over land to Kamschatka. With this view he went over to Ostend, with only ten guineas in his pocket, and proceeded by the way of Denmark and the Sound to the capital of Sweden, and endeavoured to cross the Gulph of Bothnia on the ice; but finding, when he came to the middle, that the water was not frozen, he walked round the gulph to Petersburgh. Here he found himself without stockings or shoes; but procured relief from the Portuguese ambassador, and obtained leave to proceed with a detachment of stores to Yakutz. He made this journey of six thousand miles, and there met Mr Billengs, an Englishman, whom he had known on board Captain Cook's ship. From thence he went to Oczakow, on the coast of the Kamschatka Sea; but being too late to embark that year, returned to Yakutz to winter. Here he was, on some suspicion, seized, conveyed on a sledge through Northern Tartary, and left on the frontiers of the Polish dominions. In the midst of poverty, rags, and disease, he however reached Koningsburg, where he found friends that enabled him to reach England.

On his arrival in London, he waited on Sir Joseph Banks, on whose credit he had, in his distress, received at different times 25 guineas. Sir Joseph communicated to him the views of the African Association, and pointed out the route in which they wished Africa to be explored. On his engaging at once in the enterprise, Sir Joseph asked him when he would be able to set out. "To-morrow morning," replied Ledyard, without hesitation. At this interview the president of the Royal Society declares, that he was struck with the figure of the man, the breadth of his chest, the openness of his countenance, and the rolling of his eye. Though scarcely exceeding the middle size, his figure indicated great strength and activity. Despising the accidental distinctions of society, he seemed to regard no man as his superior; but his manners, though coarse, were not disagreeable. His uncultivated genius was original and comprehensive. From the native energy of his mind, he was adventurous, curious, and unappalled by dangers; while the strength of his judgment united caution with energy. The track pointed out to him was from Cairo to Senaar, and thence westward in the latitude and supposed direction of the Niger.

He was not ignorant, that the task assigned him was arduous and big with danger; but instead of shrinking from it, he said, on the day of his departure, "I am accustomed to hardships; I have known both hunger and nakedness to the utmost extremity of human suffering; I have known what it is to have food given me as charity to a madman; and I have at times been obliged to shelter myself under the miseries of that character to avoid a heavier calamity. My distresses have been greater than I ever owned, or ever will own to any man. Such evils are terrible to bear, but they never yet had power to turn me from my purpose. If I live, I will faithfully perform, in its utmost extent, my engagement to the Society: and if I perish in the attempt, my honour will be safe; for death cancels all bonds."

After receiving his instructions and letters of recommendation, this intrepid traveller sailed from London on the 30th of June 1788; and in 36 days arrived at Alexandria. Proceeding to Cairo, where he arrived August the 17th, he visited the slave markets, and conversed with the travelling merchants of the caravans. These sources of information, generally neglected by travellers, enabled him to obtain, at a very small expence, more correct information concerning the African nations and their trade, the position of places, the nature of the country, the manner of travelling, &c. than could have been easily obtained by any other method. He thus learned, that the Arabs of the desert have an invincible attachment to liberty, though it is singular that they have no word to express liberty in their language. The Mahomedans of Africa are a trading, superstitious, and warlike set of vagabonds. He saw near 200 black slaves exposed to sale, who had been brought from the interior parts of Africa; their appearance savage, but not like [illegible] head ornaments, and their hair [illegible] of great length. Another parcel, which had come from Darfoor, were mostly women; and the beads, and some other ornaments which they wore, were Venetian. They were well formed, quite black, had the true Guinea face, and curled hair. Mr Ledyard was informed, that the king of Senaar was a merchant, and concerned in the caravans; that 20,000 negro slaves are imported into Egypt annually. Among these Senaar slaves, he saw them of a bright olive colour, but their heads uncommonly formed, the forehead the narrowest, longest, and most protuberant he ever saw.

The Senaar caravan is the most rich; that of Darfoor is not equally so, though it trades with almost the same commodities. Besides slaves, these are gum, elephants teeth, camels, and ostrich feathers; for which are received in exchange trinkets, soap, antimony, red linen, razors, scissars, mirrors, and beads. Wangara, to which the caravans also trade, was represented to Mr Ledyard as a kingdom producing much gold; but the king seems to intermeddle with commerce as well as the potentate of Senaar; for in order to deceive strangers, and prevent them from guessing at the extent of his riches, he was reported to vary continually the gold used in barter, which it is his province to regulate, and of which he issues at one time a great quantity, and at others little or none. A caravan goes from Cairo to Fezzan, which they call a journey of fifty days; and as the caravans travel about 20 miles a day, the distance must be about 1000 miles; from Fezzan to Tombuctoo is 1800 miles; from Cairo to Senaar about 600 miles.

Such was the information which Mr Ledyard derived from the merchants of the caravans in Egypt; but when he was about to verify it by his own observations, and had announced to the Association that his next dispatch would be dated from Senaar, he was seized with a bilious complaint, which frustrated the skill of the most eminent physicians, and put a period to his travels and his life at Cairo. It is needless to say how much his death was regretted, or how well he was qualified for the arduous enterprise in which he had engaged. The person who, with [illegible], could penetrate the frozen regions of Tartary, [illegible] among their churlish inhabitants, and ingratiate himself with the ferocious Moors of Egypt, could hardly have failed to obtain a kind reception from the gentle and hospitable Negro, had no untoward circumstances intervened. At Senaar, indeed, his risk would have been great; and Mr Bruce was decidedly of opinion, that a man so poorly attended as Mr Ledyard, could never have made his escape from that treacherous and ferocious people.

The

The observations of this accurate observer on the female character, though they have been repeatedly quoted in other works, are well intitled to a place here; and with them we shall conclude this sketch of his life: "I have always (says he) remarked, that women in all countries are civil and obliging, tender and humane; that they are ever inclined to be gay and cheerful, timorous and modest; and that they do not hesitate, like man, to perform a generous action. Not haughty, not arrogant, not supercilious; they are full of courtesy, and fond of society; more liable, in general, to err than man; but in general also more virtuous, and performing more good actions than he. To a woman, whether civilized or savage, I never addressed myself, in the language of decency and friendship, without receiving a decent and friendly answer. With man it has often been otherwise. In wandering over the barren plains of inhospitable Denmark, through honest Sweden, and frozen Lapland, rude and churlish Finland, unprincipled Russia, and the wide spread regions of the wandering Tartar; if hungry, dry, cold, wet, or sick, the women have ever been friendly to me, and uniformly so. And to add to this virtue (so worthy the appellation of benevolence), these actions have been performed in so free and kind a manner, that if I was dry, I drank the sweetest draught; and if hungry, I eat the coarsest morsel with a double relish." For a fuller account of *Ledyard*, see *The Transactions of the African Association*, or *A View of the Late Discoveries in Africa*.

Hyperbolic LEGS, are the ends of a curve line that partakes of the nature of the hyperbola, or having asymptots.

LEMINGTON Priors, is a village two miles east of the town of Warwick, famous for its mineral waters. One salt spring, which rises near the church yard, has been long known, as well as another which rises in the bed of the river; but the most remarkable spring was discovered in the year 1790. The waters of both springs have been analyzed with great accuracy by William Lambe, M. A. late Fellow of St John's college, Cambridge, who has given us the following synoptical table of the substances contained in them:

Gaseous Fluids contained in a Wine gallon in Cubic Inches.

	WATER OF THE NEW SPRING.	WATER OF THE OLD SPRING.
Hepatic gas	*Too small to be measured.*	*Too small to be measured.*
Azotic gas	3.5	3
Carbonic acid gas	.5	—

Solid contents of a Wine gallon in Grains.

	WATER OF THE NEW SPRING.	WATER OF THE OLD SPRING.
Carbonat of iron	.75	
Oxyds of iron and manganese	—	*Too small to be weighed.*
Oxygenated muriat of iron and manganese	*Unknown, but very small.*	*Unknown, but very small.*
Sulphur	*Unknown, but very small.*	—
Muriat of magnesia	11.5	58
Muriat of soda	430	330
Sulphat of soda	152	62
Sulphat of lime	112	146

In the course of his experiments, for which we must refer to the original memoir, in Transactions of the Manchester Society, Mr Lambe thinks he discovered the origin of the *muriatic acid*. He found a coincidence, very unexpected, between the hepatised solution of iron and the oxygenated muriat of iron. "I had almost concluded (says he), from the resemblance between the properties of this salt and the phenomena of the water, that the water contains this very salt. Now, I conclude, that they contain a matter, be it what it may, produced by the action of hepatic gas on iron. But they are the very same facts which form the basis, upon which each separate inference is built. Does it not follow, then, as a necessary consequence, that the hepatised solution itself contains a muriat of iron highly oxygenated, and that therefore *in this process muriatic acid is generated?* This conclusion seemed authorised by reason, and experiment has confirmed it."

LEMNISCATE, the name of a curve in the form of the figure of 8.

LEMON-juice, is an article of such harmless luxury, and in some cases of such real utility, that many of our readers will be pleased to know a simple method by which they may obtain it in great purity. In the article Chemistry (*Suppl.*), nº 476, we have shewn from Scheele and Dizé, how to obtain the citric acid perfectly pure, and in the form of crystals; but here we mean nothing more than to shew how it may be completely separated from that slimy substance with which it is always mixed in the lemon, without allowing it time to spoil or to acquire any disagreeable taste during the separation. This we are enabled to do by M. Brugnatelli, who, in the 2d volume of the *Annali di Chimia*, informs us, that he expressed in the common manner the juice of perfectly ripe lemons, and strained it through a piece of linen. In half an hour he strained it again, to free it from a little slimy matter which had settled at the bottom of the vessel. He then added to the juice a certain quantity of the strongest spirit of wine, and preserved the mixture for some days in a well corked bottle. During that time there was a considerable deposit, which to all appearance was of a slimy nature, and which he separated by filtering paper. If the fluid was too thick to pass through the filter, he diluted it again with spirit of wine. After this operation, the deposit remained on the paper, which was entirely covered with it; and he obtained, in the vessel placed below, the purest acid of lemons combined with spirit of wine.

If it be required to obtain the acid perfectly pure, nothing is necessary but to separate from it the spirit of wine, which can be best effected by evaporation. The acid of the lemons assumes, after it has been freed from the spirit of wine and the moisture combined with it, a yellowish colour, and becomes so strong, that by its taste it might be considered as a mineral acid.

It is not necessary to evaporate the spirit of wine in a close vessel, if the experiment is made only on a small scale; nor is there any danger that in open vessels any of the acid will be lost, as it is too fixed to be volatilised by the same degree of heat at which spirit of wine evaporates. This acid has peculiar properties, which deserve farther examination.

LENSES (see Lens and Dioptrics, *Encycl.*), are either blown or ground.

Blown Lenses are used only in the single microscope;

Lenses, Leo.

and the usual method of making them has been to draw out a fine thread of the soft white glass called *crystal*, and to convert the extremity of this into a spherule by melting it at the flame of a candle. But this glass contains lead, which is disposed to become opake by partial reduction, unless the management be very carefully attended to. We are informed, however, by Mr Nicholson, that the hard glass used for windows seldom fails to afford excellent spherules. This glass is of a clear bright green colour when seen edgewise. A thin piece was cut from the edge of a pane of glass less than one-tenth of an inch broad. This was held perpendicularly by the upper end, and the flame of a candle was directed upon it by the blow-pipe at the distance of about an inch from the lower end. The glass became soft, and the lower piece descended by its own weight to the distance of about two feet, where it remained suspended by a thin thread of glass about one five-hundredth of an inch in diameter. A part of this thread was applied endwise to the lower blue part of the flame of the candle without the use of the blow-pipe. The extremity immediately became white-hot, and formed a globule. The glass was then gradually and regularly thrust towards the flame, but never into it, until the globule was sufficiently large. A number of these were made; and being afterwards examined, by viewing their focal images with a deep magnifier, proved very bright, perfect, and round. This, as the ingenious author observes, may prove an acceptable piece of information to those eminent men (and there are many such), whose narrow circumstances, or remote situations, are obliged to have recourse to their own skill and ingenuity for experimental implements.

Ground Lenses, are such as are ground or rubbed into the desired shape, and then polished. Different shapes have been proposed for lenses; but in the article Optics, n° 252 (*Encycl.*), it has been shewn that, after all, the spherical is the most practically useful. By many of the methods of grinding, however, the artificer, with his utmost care, can only produce an approximation to a truly spherical figure; and, indeed, gentlemen have, for the most part, nothing to depend on for the sphericity of the lenses of their telescopes, but the care and integrity of the workmen. In the 41st volume of the Transactions of the Royal Society of London, a machine is described by Mr Samuel Jenkins, which, as it is contrived to turn a sphere at one and the same time on two axes, cutting each other at right angles, will produce the segment of a true sphere merely by turning round the wheels, and that without any care or skill in the workmen. The following description of this machine will enable our readers fully to comprehend its construction, and the mode of using it: A is a globe covered with cement, in which are fixed the pieces of glass to be ground. This globe is fastened to the axis, and turns with the wheel B. C is the brass cup which polishes the glass: this is fastened to the axis, and turns with the wheel D. The motion of the cup C, therefore, is at right angles with the motion of the globe A; whence it follows demonstrably, that the pieces of glass ground by this double motion must be formed into the segments of spheres.

Plate XII

LEO X. is a pontiff to whom learning, and art, and science, are so deeply indebted, that not to give a sketch of his life and character, in a Work of this kind, would be an unpardonable omission. A character of him is indeed given in the *Encyclopædia*; but it is so far from the truth, that it is difficult to conceive the prejudices under which he must have laboured by whom such a libel was drawn up.*

Leo, whose name, before his elevation to the pontificate, was *Giovanni de Medici*, was the second son of Lorenzo de Medici, justly styled the Magnificent. In the life of that great man published in this *Supplement*, the reader will see by what means, and for what purpose, he got Giovanni raised to the dignity of cardinal at so early a period of life; and in the elegant work of Roscoe, to which we there refer, he will find such instructions of Lorenzo to the cardinal as must have made a deep impression on his youthful mind.

Speaking of his promotion, Lorenzo says, "The first thing that I would suggest to you, is, that you ought to be grateful to God, and continually to recollect that it is not through your merits, your prudence, or your solicitude, that this event has taken place, but through his favour, which you can repay only by a *pious*, *chaste*, and *exemplary life*; and that your obligations to the performance of these duties are so much the greater, as in your *early years* you have given some *reasonable expectation* that your riper age may produce such fruits. It would indeed be highly disgraceful, and as contrary to your duty as to my *hopes*, if at a time when others display a greater share of reason, and adopt a better mode of life, you should forget the *precepts of your youth*, and forsake the path in which you have *hitherto trodden*."—"I well know (continues Lorenzo), that as you are now to reside at Rome, that sink of all iniquity, the difficulty of conducting yourself by these admonitions will be increased. The influence of example is itself prevalent; but you will probably meet with those, who will particularly endeavour to corrupt and incite you to vice; because, as you yourself may perceive, your early attainment of so great a dignity is not observed without envy, and those who could not prevent your receiving that honour, will secretly endeavour to diminish it, by inducing you to forfeit the good estimation of the public."—"You are not unacquainted with the great importance of the character which you have to sustain; for you well know, that all the Christian world would prosper if the cardinals were what they ought to be; because in such a case there would always be a good pope, upon which the tranquillity of Christendom so materially depends."

As this was a confidential letter from Lorenzo to his son, the first of these extracts furnishes very sufficient evidence, that Giovanni had been at least a well behaved boy, diligent in his studies, and regular in his conduct; and without supposing him remarkably religious, the admonitions of such a father, aided by his own ambition and love of letters, would surely guard him against such gross licentiousness as that of which he is accused in the *Encyclopædia*. How much he revered his father, is apparent from the letter which he wrote to his brother immediately after Lorenzo's death. "What a father (says he) have we lost! How indulgent to his children! Wonder not, then, that I grieve, that I lament, that I find no rest. Yet, my brother, I have some consolation in reflecting that I have thee, whom I shall always regard in the place of a father." Surely this is not the language of a gross sensualist, or of one who could soon

forget

forget the salutary admonitions of such a parent as Lorenzo de Medici. But it is needless to infer the decency of his character by such reasonings as these. The story published in the *Encyclopædia*, of the manner in which the Cardinal de Medici obtained the tiara, cannot possibly be true. The reader, who shall turn to the article POPE in that Work, will find that the conclave, when fitted up for an election, is so large a place, that we may safely affirm, that had the cardinal's ulcer discharged matter so fetid as to *poison all the cells*, the assertion of the physicians would have been verified, and that in the then state of the healing art, the new pope could not have survived a month. Let it be remembered, too, that Leo, at his accession, was not 30, but 37 years of age, and that he had long ruled in Florence with sovereign sway by the same means which had upheld the authority of his father. The follies of youth, therefore, had he ever been remarkable for such follies, must have been over with him; and in such a state as Florence he could not have maintained the authority of Lorenzo, without exhibiting not only Lorenzo's liberality, but likewise his decency of manners.

The next charge brought against Leo in the *Encyclopædia* is, that he published general indulgences throughout Europe; and this is so expressed as to lead the ill informed reader to suppose, either that no such indulgences had ever been published by any of his predecessors, or that there was something peculiarly scandalous in Leo's mode of publishing them. Both suppositions, however, are erroneous. The historian of the council of Trent, who certainly was not partial to the court of Rome, or to the dispensing power of the pope, has shewn, that the practice of raising money by the publication of indulgences, had prevailed ever since the year 1100; that many former popes had raised money in this manner for purposes much less laudable than those which Leo had in his eye; and that the real cause of Luther's attack upon Leo's indulgences was, that they were preached through Saxony by the Dominican friars; whereas the preaching of former indulgences had been committed to the hermits of St Augustine, the order to which Luther himself belonged!

Leo is likewise accused in the *Encyclopædia* of being a professed infidel, and of having called Christianity "a fable very profitable for him and his predecessors." But of the truth of this accusation there seems not to be the shadow of evidence. Leo had too much sense to utter expressions of this kind, even had he been an unbeliever in his heart; for he could not possibly expect that his indulgences and pardons would be purchased, had he declared in such strong terms that they were of no value. Father Paul indeed says, that he was not a deep divine, or so pious as some of his predecessors; but he affirms, that he *adorned the papacy* with many admirable qualities; that he was learned, affable, liberal, *good*; that he delighted in healing differences, and that his equal had not, for many years, filled the chair of St Peter. Surely this is not the character of a profane infidel!

Leo has been charged with raising his own family to grandeur at the expence of justice; and of dealing treacherously, in order to effect this purpose, both with the emperor and with the French king. But the charge is either false or greatly exaggerated. He lost no opportunity indeed of aggrandizing his relations, well knowing, that in order to secure to them any lasting benefit, it was necessary that they should be powerful enough to defend themselves, after his death, from the rapacious aims of succeeding pontiffs; but, in prosecuting this plan, he was so far from acting tyrannically or injuriously to others, that during his pontificate, the papal dominions enjoyed a degree of tranquillity superior to any other Italian state. During the contests that took place between the emperor and the French king, so far from acting treacherously, he distinguished himself by his moderation, his vigilance, and his political address; on which account he is justly celebrated by an eminent historian of our own *, as "the only prince of the age who observed the motions of the two contending monarchs with a prudent attention, or who discovered a proper solicitude for the public safety."

* Dr Robertson.

We trust that no zealous Protestant will think we have employed our time ill, in vindicating the character of this splendid pontiff; for good learning, and, of course, true religion, are more indebted to Leo X. than to any other individual of the age in which he lived, his father Lorenzo alone excepted.

Leo Minor, the *Little Lion*, a constellation of the northern hemisphere, and one of the new ones that were formed out of what were left by the ancients, under the name of *Stellæ Informes*, or unformed stars. See ASTRONOMY, n° 406, *Encycl.*

LESLIE (Charles), was a man so eminent for his learning, his talents, and his piety, that a fuller account of him than that which is given in the *Encyclopædia* must be acceptable to our Christian readers. He was the second son of Dr John Leslie bishop of Clogher in Ireland, who was descended from an ancient family in the north of Scotland, and being an admirable scholar, rose to the dignity of bishop of Orkney in his own country, whence he was translated, in 1633, to Raphoe in Ireland, and afterwards, in 1661, to the see of Clogher.

Our author was born in Ireland, but in what year we have not learned. A ludicrous story goes indeed of his having been begotten in prison, and of his father having said that he hoped he would, in consequence become the greatest scourge of the covenanters that Great Britain or Ireland had ever seen. This story, with all its circumstances as told to us, can hardly be true; but we think it could not have been fabricated, had not Charles Leslie been born within a year of Cromwell's conquest of Ireland, when the good bishop, having sustained a siege in his castle of Raphoe against that arch rebel, was some time kept in close confinement.

We are equally ignorant of the school where he was educated as of the year of his birth; but we know that he had his academical education in Trinity College, Dublin, where he took the degree of master of arts. In the year 1671, he lost his father, when he came over to England, and, entering himself in the temple, studied law for some years, but afterwards relinquished it for the study of divinity. In 1680, he was admitted into holy orders; and, in 1687, was made chancellor of Connor.

About this period he rendered himself particularly obnoxious to the Popish party in Ireland, by his zealous opposition to them, which was thus called forth. Roger Boyle, bishop of Clogher, dying in 1687, Patrick Tyrrel was made titular Popish bishop, and had the revenues of the see assigned him by king James. He set

Biographical Dictionary.

 up

 up a convent of friars in Monaghan: and, fixing his habitation there, held a public visitation of his clergy with great solemnity; when, some subtle logicians attending him, he was so insolent as to challenge the Protestant clergy to a public disputation. Leslie undertook the task, and performed it to the satisfaction of the Protestants; though it happened, as it generally does at such contests, that both sides claimed the victory. He afterwards held another public disputation with two celebrated Popish divines, in the church of Tynan, in the diocese of Armagh, before a very numerous assembly of persons of both religions; the issue of which was, that Mr John Stewart, a Popish gentleman, solemnly renounced the errors of the church of Rome.

As the Papists had got possession of an Episcopal see, they engrossed other offices too; and a Popish high-sheriff was appointed for the county of Monaghan. This proceeding alarmed the gentlemen in that county; who, depending much on Leslie's knowledge as a justice of peace, repaired to him, then confined, by the gout, to his house. He told them, that it would be as illegal in them to permit the sheriff to act as it would be in him to attempt it. But they insisting that he should appear himself on the bench at the next quarter sessions, and all promising to stand by him, he was carried thither with much difficulty and in great pain. When the sheriff appeared, and was taking his place, he was asked whether he was legally qualified? to which he answered pertly, "That he was of the king's own religion, and it was his majesty's will that he should be sheriff." Leslie replied, "That they were not inquiring into his majesty's religion, but whether he (the pretended sheriff) had qualified himself according to law, for acting as a proper officer; that the law was the king's will, and nothing else to be deemed such; that his subjects had no other way of knowing his will, but as it is revealed to them in his laws; and it must always be thought to continue so, till the contrary is notified to them in the same authentic manner." Upon this, the bench unanimously agreed to commit the pretended sheriff for his intrusion and arrogant contempt of the court. Leslie also committed some officers of that tumultuary army which the Lord Tyrconnel raised for robbing the country.

In this spirited conduct Leslie acted like a sound divine and an upright magistrate; but though he thought himself authorised to resist the illegal mandates of his sovereign, like many other great and good men, he distinguished between active and passive obedience; and felt not himself at liberty to transfer his allegiance from that sovereign to another. Refusing therefore to take the oaths to king William and queen Mary, he was deprived of all his preferments; and in 1689 he removed with his family to England, where he published the following works, besides those already noticed in the *Encyclopedia*: 1. Answer to Archbishop King's State of the Protestants in Ireland. 2. Cassandra, concerning the new Associations, &c. 1703, 4to. 3. Rehearsals; at first a weekly paper, published afterwards twice a-week in a half-sheet, by way of dialogue on the affairs of the times; begun in 1704, and continued for six or seven years. 4. The Wolf stripped of his Shepherd's Clothing, in Answer to Moderation a Virtue, 1704, 4to. The pamphlet it answers was written by James Owen. 5. The Bishop of Sarum's [Burnet's] proper Defence, from a Speech said to be spoken by him against occasional conformity, 1704, 4to. 6. The new Association of those called Moderate Churchmen, &c. occasioned by a pamphlet, intitled, The Danger of Priestcraft, 1705, 4to. 7 The new Association, part 2d, 1705, 4to. 8. The Principles of Dissenters concerning Toleration and occasional Conformity, 1705, 4to. 9. A Warning for the Church of England, 1706, 4to. Some have doubted whether these two pieces were his. 10. The good old Cause, or Lying in Truth; being a second Defence of the Bishop of Sarum from a second Speech, &c. 1710. For this a warrant was issued out against Leslie. 11. A Letter to the Bishop of Sarum, in Answer to his Sermon after the Queen's Death, in Defence of the Revolution, 1715. 12. Salt for the Leech. 13. The Anatomy of a Jacobite. 14. Gallienus redivivus. 15. Delenda Carthago. 16 A Letter to Mr William Molyneux, on his Case of Ireland's being bound by the English Acts of Parliament. 17. A Letter to Julian Johnson. 18. Several Tracts against Dr Higden and Mr Hoadly. 19. A Discourse, shewing who they are that are now qualified to administer Baptism. 20. The History of Sin and Heresy, &c. 1698, 8vo. 21. The Truth of Christianity demonstrated, in a Dialogue between a Christian and a Deist, 1711, 8vo.—Against the Papists: 22. Of private Judgment and Authority in Matters of Faith. 23. The Case stated between the Church of Rome and the Church of England, &c 1713. 24. The true notion of the Catholic Church, in Answer to the Bishop of Meaux's Letter to Mr Nelson, &c.

Besides these, he published the four following tracts: 25. A Sermon preached in Chester, against Marriages in different Communions, 1702, 8vo. This sermon occasioned Mr Dodwell's discourse upon the same subject. 26. A Dissertation concerning the Use and Authority of Ecclesiastical History. 27. The Case of the Regal and the Pontificate. 28. A Supplement, in Answer to a Book, intitled, The regal Supremacy in Ecclesiastical Affairs asserted, &c. These two last pieces were occasioned by the dispute about the rights of convocation, between Wake, &c. on one side, and Atterbury and his friends, among whom was Leslie, on the other.

It is said by the authors of the Biographical Dictionary, that, in consequence of a publication of his, intitled, "The hereditary right of the crown of England asserted," he was under the necessity of leaving the kingdom; and that he repaired to the Pretender at Bar le duc, where he was allowed to officiate, in a private chapel, after the rites of the church of England; and where he endeavoured, though in vain, to convert the Pretender to the Protestant religion.

That he repaired to *Bar le duc*, and endeavoured to convert to the church of England him whom he considered as the rightful sovereign of England, is indeed true; but we have reason to believe that this was not in consequence of his being obliged to leave the kingdom. There is, in the first place, some grounds to believe, that "The hereditary right of the crown of England asserted" was not written by him; and there is still in existence undoubted evidence, that, in consequence of his great fame as a polemic, he was sent to *Bar le duc* for the express purpose of endeavouring to convert the son of James II. by some gentlemen of fortune in England, who wished to see that prince on the throne of

... he had the honour, 16 or 17 years ago, to be known to the grand-daughter of one of those gentlemen—a lady of the strictest veracity; and from her he received many anecdotes of Leslie and his associates, which, as he did not then foresee that he should have the present occasion for them, he has suffered to slip from his memory. That lady is still alive, and we have reason to believe is in possession of many letters by Leslie, written in confidence to her grandfather, both from *Bar le duc* and from St Germains; and by the account which she gave of these letters, Leslie appears to have considered his prince as a weak and incorrigible bigot, though, in every thing but religion, an amiable and accomplished man. This may have been his genuine character; for we all know that it was the character of his father; but it is not of him that we are writing.

Mr Leslie having remained abroad from the year 1709 till 1721, returned that year to England, resolving, whatever the consequences might be, to die in his own country. Some of his friends acquainting lord Sunderland with his purposes, implored his protection for the good old man, which his lordship readily and generously promised. Mr Leslie had no sooner arrived in London, than a member of the house of commons officiously waited on lord Sunderland with the news, but met with such a reception from his lordship as the malice of his errand deserved. Our author then went over to Ireland, where he died April 13. 1722. at his own house at Glaslough in the county of Monaghan.

His character may be summed up in a few words. Consummate learning, attended by the lowest humility, the strictest piety without the least tincture of moroseness, a conversation to the last degree lively and spirited, yet to the last degree innocent, made him the delight of mankind, and leaves what Dr Hickes says of him unquestionable, that he made more converts to a sound faith and holy life than any other man of our times.

A charge, however, has been lately brought against him of such a nature, as, if well founded, must detract not only from his literary fame, but also from his integrity. "The short and easy Method with the Deists" is unquestionably his most valuable, and apparently his most original work; yet this tract is published in French among the works of the Abbé St Real, who died in 1692; and therefore it has been said, that unless it was published in English prior to that period, Charles Leslie must be considered as a shameless plagiary.

The English work was certainly not published prior to the death of Abbé St Real; for the first edition bears date July 17th 1697; and yet many reasons conspire to convince us, that our countryman was no plagiary. There is indeed a striking similarity between the English and the French works; but this is no complete proof that the one was copied from the other. The article PHILOLOGY in the *Encyclopædia Britannica*, of which Dr Doig is the author, was published the very same week with Dr Vincent's dissertation on the Greek verb. It was therefore impossible that either of these learned men, who were till then strangers to each others names, could have stolen aught from the other; and yet Dr Vincent's derivation of the Greek verb bears as striking a resemblance to Dr Doig's as the Abbé St Real's work does to Charles Leslie's. In the article MIRACLE (*Encycl.*), the credibility of the gospel miracles is established by an argument, which the author certainly borrowed from no man, and which the late principal Campbell considered as original; yet within half a year of the publication of that article, the credibility of the gospel miracles was treated in the very same manner by F. SAYERS, M. D. though there is in his dissertation complete internal evidence that he had not seen the article in the *Encyclopædia*. Not many months ago, the author of this sketch reviewed, in one of the journals, the work of a friend, which was at the same time reviewed in another journal, that at this moment he has never seen. Yet he has been told by a friend, who is much versant in that kind of reading, and knows nothing of his concern with either review, that the book in question must, in both journals, have been reviewed by the same hand; because in both the same character is given of it in almost the very same words!

After these instances of apparent plagiarism, which we know to be *only* apparent, has any man a right to say that Charles Leslie and the Abbé St Real might not have have treated their subject in the way that they have done, without either borrowing from the other? The coincidence of arrangement and reasoning in the two works is indeed very surprising; but it is by no means so surprising as the coincidence of etymological deductions which appears in the works of the Doctors Doig and Vincent. The divines reason from the acknowledged laws of human thought; the reasonings of the grammarians, with all due deference to their superior learning, we cannot help considering as sometimes fanciful.

But this is not all that we have to urge on the subject. If there be plagiarism in the case, and the identity of titles looks very like it, it is infinitely more probable that the editor of St Real's works stole from Leslie, than that Leslie stole from St Real, unless it can be proved that the works of the Abbé, and this work in particular, were published before the year 1697. At that period, the English language was very little read or understood on the continent; whilst in Britain the French language was, by *scholars*, as generally understood as at present. Hence it is, that so many Frenchmen, and indeed foreigners of different nations, thought themselves safe in pilfering science from the British philosophers*; whilst there is not, that we know, one well authenticated instance of a British philosopher appropriating to himself the discoveries of a foreigner. If, then, such men as LEIBNITZ, John BERNOULLI, and DES CARTES, trusting to the improbability of detection, condescended to pilfer the discoveries of HOOKE, NEWTON, and HARRIOT, is it improbable that the editor of the works of St Real would claim to his friend a celebrated tract, of which he knew the real author to be obnoxious to the government of his own country, and therefore not likely to have powerful friends to maintain his right?

But farther, Burnet, bishop of Sarum, was an excellent scholar, and well read, as every one knows, in the works of foreign divines. Is it conceivable, that this prelate, when smarting under the lash of Leslie, would have let slip so good an opportunity of covering with disgrace his most formidable antagonist, had he known that antagonist to be guilty of plagiarism from the writings of the Abbé St Real? Let it be granted, however,

Leslie.

* See *Quantity* (Encyc.), *Astronomy*, *Dynamics*, *Impulsion*, and *Harriot*, in this Suppl.

Leslie || Licenser.

however, that Burnet was a stranger to these writings and to this plagiarism; it can hardly be supposed that *Le Clerc* was a stranger to them likewise. Yet this author, when, for reasons best known to himself, he chose (1706) to depreciate the argument of *the short method*, and to traduce its author as ignorant of ancient history, and as having brought forward his four marks for no other purpose than to put the deceitful traditions of Popery on the same footing with the most authentic doctrines of the gospel, does not so much as insinuate that he borrowed these marks from a Popish abbé, though such a charge, could he have established it, would have served his purpose more than all his rude railings and invective. But there was no room for such a charge. In the second volume of the works of St Real, published in 1757, there is indeed a tract entitled *Methode Courte et Aisée pour combattre les Deistes*; and there can be little doubt but that the publisher wished it to be considered as the work of his countryman. Unfortunately, however, for his design, a catalogue of the Abbé's works is given in the first volume; and in that catalogue the *Methode Courte et Aisée* is not mentioned.

We have dwelt thus long on *The Short and Easy Method with the Deists*, because it is one of the ablest works that ever was written in proof of the Divine origin of the Jewish and Christian Scriptures; a work of which the merit is acknowledged by Lord Bolingbroke, and which, as has been observed elsewhere (see Theology, n° 16. *Encycl.*) Dr Conyers Middleton confesses to be unanswerable. If by men of science we be thought to have spent our time well in vindicating the rights of our illustrious philosophers Hooke and Newton, to discoveries which have been unjustly claimed by the philosophers of Germany and France; we will not surely by the friends of Christianity be thought to have employed our time ill in vindicating Leslie's claim to this decisive argument in support of our holy religion.

LEVER, the first of the mechanical powers, for the properties of which see Mechanics; and for a demonstration of its fundamental property, see Steel yard, both in the *Encyclopædia*.

LICENSER of Books (see Liberty *of the Press*, *Encycl.*), has been an officer in almost every civilized nation, till the end of the last century that the office was abolished in Great Britain. Professor Beckmann, with his usual industry*, has proved that such an office was established not only in the Roman Empire, but even in the republic, and in the free states of ancient Greece. At Athens, the works of Protagoras were prohibited; and all the copies of them which could be collected were burnt by the public crier. At Rome, the writings of Numa, which had been found in his grave, were, by order of the senate, condemned to the fire, because they were contrary to the religion which he had introduced. As the populace at Rome were, in times of public calamity, more addicted to superstition than seemed proper to the government, an order was issued, that all superstitious and astrological books should be delivered into the hands of the prætor. This order was often repeated: and the emperor Augustus caused more than twenty thousand of these books to be burnt at one time. Under the same emperor the satirical works of Labienus were condemned to the fire, which was the first instance of this nature; and it is related as something singular, that, a few years after, the writings of the person who had been the cause of the order for that purpose shared the like fate, and were also publicly burnt. When Cremutius Cordus, in his history, called C. Cassius the last of the Romans, the senate, in order to flatter Tiberius, caused the book to be burnt; but a number of copies were saved by being concealed. Antiochus Epiphanes caused the books of the Jews to be burnt; and in the first centuries of our æra the books of the Christians were treated with equal severity, of which Arnobius bitterly complains. We are told by Eusebius, that Dioclesian caused the sacred Scriptures to be burnt. After the spreading of the Christian religion the clergy exercised, against books that were either unfavourable or disagreeable to them, the same severity which they had censured in the heathens as foolish and prejudicial to their own cause.

* *History of Inventions*, vol 3.

Licenser, Lichen.

Soon after the invention of printing, laws began to be made for subjecting books to examination; a regulation proposed even by Plato; and which has been wished for by many since. Our author gives a great deal of curious information on this important subject, which our limits do not permit us to repeat; but it is apparent from his work, that the liberty of the press is but a modern privilege; and that it has not been enjoyed completely in any country but this happy island.

LICHEN (see *Encycl.*), is a genus of plants, of which the most valuable species seems to be the Lichen Rocella, or *Argol*. As that species has not been noticed in the article referred to, the following account of it from Professor Beckmann will be acceptable to many of our readers:

It is found in abundance in some of the islands near the African coast, particularly in the Canaries, and in several of the islands in the Archipelago. It grows upright, partly in single, partly in double stems, which are about two inches in height. When it is old, these stems are crowned with a button sometimes round, and sometimes of a flat form, which Tournefort, very properly, compares to the excrescences on the arms of the sepia. Its colour is sometimes a light, and sometimes a dark grey. Of this moss, with lime, urine, and alkaline salts, is formed a dark red paste, which in commerce has the same name, and which is much used in dyeing. That well-known substance called lacmus is also made of it.

Theophrastus, Dioscorides, and their transcriber Pliny, give the name of *Phycos thalassion*, or *pontion*, to this plant, which, notwithstanding its name, is not a sea weed but a moss; as it grew on the rocks of different islands, and particularly on those of Crete or Candia. It had, in their time, been long used for dyeing wool, and the colour it gave when fresh was so beautiful, that it excelled the ancient purple, which was not red, as many suppose, but violet. Pliny tells us, that with this moss dyers gave the ground or first tint to those cloths which they intended to dye with the costly purple. When it was first employed as a dye by the moderns, is not so certain, though the Professor has proved, we think completely, that it must have been at least as early as the beginning of the 14th century.

"Among the oldest and principal Florentine families (says he), is that known under the name of the Oricellarii

Lichen. Oricellarii or Rucellarii, Rofcellai or Rucellai, feveral of whom have diftinguifhed themfelves as ftatefmen and men of letters. This family are defcended from a German nobleman, named Ferro or Frederigo, who lived in the beginning of the twelfth century. One of his defcendants, in the year 1300, carried on a great trade in the Levant, by which he acquired confiderable riches, and returning at length to Florence, with his fortune, firft made known in Europe the art of dyeing with argol. It is faid, that a little before his return from the Levant, happening to make water on a rock covered with this mofs, he obferved, that the plant, which was there called *refpio*, or *refpo*, and in Spain *orciglia*, acquired by the urine a purple, or, as others fay, a red colour. He therefore tried feveral experiments; and when he had brought to perfection the art of dyeing wool with this plant, he made it known at Florence, where he alone practifed it for a confiderable time, to the great benefit of the ftate. From this ufeful invention, the family received the name of Oricellarii, from which, at laft, was formed Rucellai." The Profeffor, however, does not believe that this Florentine difcovered the dye by means of the above-mentioned accident, but that he learned the art in the Levant, and on his return taught it to his countrymen.

"Our dyers do not purchafe raw argol, but a pafte made of it, which the French call *orfeille en pâte*. The preparation of it was for a long time kept a fecret by the Florentines. The perfon who, as far as I know, made it firft known was Rofetti; who, as he himfelf tells us, carried on the trade of dyer at Florence. Some information was afterwards publifhed concerning it by Imperati * and Micheli the botanift †. In later times this art has been much practifed in France, England, and Holland. Many druggifts, inftead of keeping this pafte in a moift ftate with urine, as they ought, fuffer it to dry, in order to fave a little dirty work. It then has the appearance of a dark violet-coloured earth, with here and there fome white fpots in it.

* Lib. xxvii c. 9.
† *Nova Plantarum genera Florentiae*, 1729.

"The Dutch (continues our author), who have found out better methods than other nations of manufacturing many commodities, fo as to render them cheaper, and thereby to hurt the trade of their neighbours, are the inventors alfo of lacmus, a preparation of argol, called *orfeille en pierre*, which has greatly leffened the ufe of that *en pâte*, as it is more eafily tranfported and preferved, and fitter for ufe; and as it is befides, if not cheaper, at leaft not dearer. This art confifts, undoubtedly, in mixing with that commodity fome lefs valuable fubftance, which either improves or does not much impair its quality, and which, at the fame time, increafes its weight (A). Thus do they pound cinnabar and fmalt finer than other nations, and yet fell both thefe articles cheaper. Thus do they fift cochineal, and fell it cheaper than what is unfifted.

"It was for a long time believed, that the Dutch prepared their lacmus from thofe linen rags which in the fouth of France are dipped in the juice of the *croton tinctorium*; but at prefent, it is almoft certainly known, that *orfeille en pâte* is the principal ingredient in *orfeille en pierre* that is in lacmus; and for this curious information we are indebted to Ferber. But whence arifes the fmell of the lacmus, which appears fo like that of the Florentine iris?" Some of the latter may, perhaps, be mixed with it; for our author thinks, that he has obferved in it fmall indiffoluble particles, which may have been bits of the roots. The addition of this fubftance can be of no ufe to improve the dye; but it may increafe the weight, and give the lack more body; and perhaps it may be employed to render imperceptible fome unpleafant fmell, for which purpofe the roots of that plant are ufed on many other occafions.

Light. LIGHT, it has been obferved in the article CHEMISTRY, n° 319. (*Suppl.*), confifts of rays differently flexible. This was eftablifhed by fome well devifed experiments made by Henry Brougham, Efq; of which it may be proper to give an account here.

In the firft experiment, he darkened his chamber in the ufual way, and let a beam of the fun's light into it through the hole of a metal plate fixed in the fhutter of the window, [illegible]th of an inch in diameter. At the hole within the room he placed a prifm of glafs, of which the refracting angle was 45 degrees, and which was everywhere covered with black paper, except a fmall part on each fide; and through this part the light was refracted fo as to form a diftinct fpectrum on a chart at fix feet diftance from the window. In the rays, at two feet from the prifm, he placed a black unpolifhed pin, of which the diameter was [illegible]th of an inch, parallel to the chart, and in a vertical pofition. The fhadow of the pin was found in the fpectrum; and this fhadow had a confiderable penumbra, which was broadeft and moft diftinct in the violet part, narroweft and moft confufed in the red, and of an intermediate thicknefs and diftinctnefs in the intermediate colours. The penumbra was bounded by curvilinear fides, convex towards the axis to which they approached as their afymptote, fo as to be neareft to it in the place of the leaft refrangible rays. By moving the prifm on its axis, and caufing the colours to afcend and defcend on any bodies that were ufed inftead of the pin, the red, wherever they fell, made the leaft, and the violet the greateft fhadow.

In the next experiment, a fcreen was fubftituted in the place of the pin; and this fcreen had a large hole, on which was a brafs plate, pierced with a fmall hole [illegible]d of an inch in diameter. While an affiftant moved the prifm flowly on its axis, the author obferved the round image made by the different rays paffing through the hole to the chart; that made by the red was greateft, that of the violet leaft, and that of each intermediate rays was of an intermediate fize. When the fharp blade of a knife was held at the back of the hole, "fo as to produce the fringes mentioned by Grimaldo and Newton, thefe fringes in the red were broadeft and moft moved inwards to the fhadow, and moft dilated when the knife was moved over the hole; and the hole itfelf on the chart was more dilated during the motion when illuminated by the red than when illuminated by any other of the rays, and leaft of all when illuminated by the violet."

From thefe two experiments, the author infers "that the rays of the fun's light differ in degree of flexibility, and

(A) As dry lacmus is much cheaper than moift, it may be readily fuppofed that it is adulterated with fand and other fubftances. *Valentini Hiftoria fimplicium*. Francf. ad Moen. 1716. fol. p. 152.

Limbers ‖ Lotus.

and that those which are least *refrangible* are *most inflexible*." From other experiments, he concludes, that the *most inflexible* rays are also *most deflexible*. In the sequel of his paper, he ascertains the proportion which the angle of *inflection* bears to that of *deflection* at equal incidences, and the proportion which the different *flexibilities* of the different rays bear to one another. We shall give an account of some other experiments made by him, and of the inferences drawn from them, under the word REFLEXITY, to which a reference has already been made.

LIMBERS, in artillery, a sort of advanced train, joined to the carriage of a cannon on a march. It is composed of two shafts, wide enough to receive a horse between them, called the *fillet horse*: these shafts are joined by two bars of wood, and a bolt of iron at one end, and mounted on a pair of rather small wheels. Upon the axle-tree rises a strong iron spike, which is put into a hole in the hinder part of the train of the gun-carriage, to draw it by. But when a gun is in action, the limbers are taken off, and run out behind it.

LIMIT OF A PLANET, has been sometimes used for its greatest heliocentric latitude.

LIMITED Problem, denotes a problem that has but one solution, or some determinate number of solutions; as to describe a circle through three given points that do not lie in a right line, which is limited to one solution only; to divide a parallelogram into two equal parts by a line parallel to one side, which admits of two solutions, according as the line is parallel to the length or breadth of the parallelogram; or to divide a triangle in any ratio by a line parallel to one side, which is limited to three solutions, as the line may be parallel to any of the three sides.

LOCAL PROBLEM, is one that is capable of an infinite number of different solutions; because the point, which is to solve the problem, may be indifferently taken within a certain extent; as suppose any where in such a line, within such a plane figure, &c. which is called a *geometrical Locus*.

A local problem is *simple*, when the point sought is in a right line; *plane*, when the point sought is in the circumference of a circle; *solid*, when it is in the circumference of a conic section; or *sursolid*, when the point is in the perimeter of a line of a higher kind.

LOCI, the plural of

LOCUS, a line by which a local or indeterminate problem is solved; or a line of which any point may equally solve an indeterminate problem. See ALGEBRA, *Encycl.*

LOGISTIC CURVE, the same with *LOGARITHMIC Curve*, for which see *Encycl.*

LOGISTICS, or *LOGISTICAL Arithmetic*, a name sometimes employed for the arithmetic of sexagesimal fractions, used in astronomical computations.

The same term has been used for the rules of computations in algebra, and in other species of arithmetic: witness the logistics of Vieta and other writers.

Shakerly, in his *Tabulæ Britannicæ*, has a table of logarithms adapted to sexagesimal fractions, and which he calls Logistical Logarithms; and the expeditious arithmetic, obtained by means of them, he calls Logistical Arithmetic.

LIBYAN LOTUS has been described (*Encycl.*) under the title RHAMNUS; but the following additional particulars from Mr Park will be acceptable to our botanical readers:

Lotus, Lowang.

The lotus is very common in all the countries which our author visited, and he had an opportunity to make a drawing of a branch in flower, of which an engraving is published in his travels, that with his permission we have copied (see Plate XXX.). The lotus produces fruit which the negroes call *tomberongs*. These are small farinaceous berries, of a yellow colour and delicious taste. They are much esteemed by the natives, who convert them into a sort of bread, by exposing them for some days to the sun, and afterwards pounding them gently in a wooden mortar, until the farinaceous part of the berry is separated from the stone. This meal is then mixed with a little water, and formed into cakes; which, when dried in the sun, resemble in colour and flavour the sweetest gingerbread. The stones are afterwards put into a vessel of water, and shaken about so as to separate the meal which may still adhere to them; this communicates a sweet and agreeable taste to the water, and with the addition of a little pounded millet, forms a pleasant gruel called *fondi*, which is the common breakfast in many parts of Ludamar, during the months of February and March. The fruit is collected by spreading a cloth upon the ground, and beating the branches with a stick. Our author thinks there can be little doubt of this being the lotus mentioned by Pliny, as the food of the Lybian Lotophagi. An army may very well have been fed with the bread made of the meal of the fruit, as is said by Pliny to have been done in Lybia; and as the taste of the bread is sweet and agreeable, it is not likely that the soldiers would complain of it.

LOWANG, a Chinese island of some extent in the neighbourhood of the CHUSAN-Isles, which see in this *Supplement*. Some of the gentlemen belonging to the British embassy went ashore on Lowang, which they described as naked both of trees and of cattle. They examined particularly a small level plain recovered from the sea, which was kept out by an embankment of earth, at least thirty feet thick. The quantity of ground gained by it seemed scarcely to be worth the labour that it must have cost. The plain was indeed cultivated with the utmost care, and laid out chiefly in rice-plats, supplied with water collected from the adjacent hills into little channels, through which it was conveyed to every part of those plantations. It was manured, instead of the dung of animals, with matters more offensive to the human senses, and which are not very generally applied to the purposes of agriculture in England. Earthen vessels were sunk into the ground for the reception of such manure; and for containing liquids of an analogous nature, in which the grain was steeped previously to its being sown; an operation which is supposed to hasten the growth of the future plant, as well as to prevent any injury from insects in its tender state.

The party fell in with a peasant who, though struck with their appearance, was not so feared by it as to shun them. He was dressed in loose garments of blue cotton, a straw hat upon his head fastened by a string under his chin, and half boots upon his legs. He seemed to enter into the spirit of curiosity, naturally animating travellers, and readily led them towards an adjoining village.

village. Passing by a small farm house, they were invited into it by the tenant, who, together with his son, observed them with astonished eyes. The house was built of wood, the uprights of the natural form of the timber. No ceiling concealed the inside of the roof, which was put together strongly, and covered with the straw of rice. The floor was of earth beaten hard, and the partitions between the rooms consisted of mats hanging from the beams. Two spinning wheels for cotton were seen in the outer room; but the seats for the spinners were empty. They had probably been filled by females, who retired on the approach of strangers; while they remained, none of that sex appeared. Round the house were planted clusters of bamboo, and of that species of palm, of which each leaf resembles the form of a fan; and, used as such, becomes an article of merchandize.

LOXODROMIC Curve, or *Spiral*, is the same as the rhumb line, or path of a ship sailing always on the same course in an oblique direction, or making always the same angle with every meridian. It is a species of logarithmic spiral, described on the surface of the sphere, having the meridians for its radii.

LOXODROMICS, the art or method of oblique sailing, by the loxodromic or rhumb line.

LUCIOLE, a name given in the *Annales de Chimie* to the *Lampyris Italica* (See Lampyris, *Encycl.*). According to Dr Carradori, the light of the luciole does not depend on the influence of any external cause, but merely on the will of those insects. While they fly about at freedom, their shining is very regular; but when they are once in our power, they shine very irregularly, or do not shine at all. When they are molested, they emit a frequent light, which appears to be a mark of their resentment. When placed on their backs, they shine almost without interruption, making continual efforts to turn themselves from that position. In the daytime it is necessary to torment them in order to make them shine; and thence it follows, that the day to them is the season of repose. The luciole emit light at pleasure from every point of their bellies, which proves that they can move all the parts of their viscera independently of each other. They can also render their phosphorescence more or less vivid, and continue it as long as they please.

A slight compression deprives the luciole of their power of ceasing to shine. The author is inclined to believe, that the movement by which they conceal their light is executed by drawing back their phosphoric substance into a particular membrane or tunic. He supposes also, that the sparkling consists in a trembling or oscillation of the phosphoric mass. He is of opinion, that there is no emanation of a phosphoric substance, and that the whole phenomenon takes place in the interior part of the luminous viscera. When the shining is at its greatest degree of height, it is so strong that a person may by it easily distinguish the hours on the smallest watch, and the letters of any type whatever.

The phosphoric part of the luciole does not extend farther than to the extreme rings of the belly. It is there inclosed in a covering composed of two portions of membranes, one of which forms the upper, and the other the lower, part of the belly, and which are joined together. Behind this receptacle is placed the phosphorus, which resembles a paste, having the smell of garlic, and very little taste. The phosphoric matter issues from a sort of bag on the slightest pressure; when squeezed out, this matter loses its splendour in a few hours, and is converted into a white dry substance. A portion of the phosphoric belly put into oil, shone only with a feeble light, and was soon extinguished. In water, a like portion shone with the same vivacity as in the air, and for a much longer time. The author thence concludes, that the phosphorescence of the luciole is not the effect of slow inflammation, nor of the fixation of azotic gas, as the oil in which they shine does not contain a single air-bubble: besides, the phosphorus of these insects shines in a barometrical vacuum. The observation made by Foster, that the luciole sed a more vivid light in oxygen gas than in atmospheric air, does not, according to Carradori, depend upon a combustion more animated by the inspiration of this gas, but on the animals feeling themselves, while in that gas, in a better condition. "Whence, then, arises (says the author) the phosphoric light of the luciole? I am of opinion (adds he), that the light is peculiar and innate in these insects, as several other productions are peculiar to other animals. As some animals have the faculty of accumulating the electric fluid, and of keeping it condensed in particular organs, to diffuse it afterwards at pleasure, there may be other animals endowed with the faculty of keeping in a condensed state the fluid which constitutes light. It is possible, that by a peculiar organization they may have the power of extracting the light which enters into the composition of their food, and of transmitting it to the reservoir destined for that purpose, which they have in their abdomen. It is not even impossible that they may have the power to extract from the atmospheric air the luminous fluid, as other animals have the power of extracting from the same air, by a chemical process, the fluid of heat."

Carradori discovered, that the phosphorescence of the luciole is a property independent of the life of these animals, and that it is chiefly owing to the soft state of the phosphoric substance. Its light is suspended by drying, and it is again revived by softening it in water; but only after a certain time of desiccation. Reaumur, Beccaria, and Spallanzani, observed the same thing in regard to the *pholades* and the *medusa*.

By plunging the luciole alternately into lukewarm and cold water, they shine with vivacity in the former, but their light becomes extinct in the latter; which, according to the author, depends on the alternate agreeable and disagreeable sensation which they experience. In warm water their light disappears gradually. Dr Carradori tried on the luciole and their phosphorus the action of different saline and spirituous liquors, in which they exhibited the same appearances as other phosphoric animals. These last experiments prove that the phosphoric matter of the luciole is only soluble in water.

LUDAMAR, a Moorish kingdom in the interior of Africa, of which the capital Benorm is placed by Major Rennel in 15° N. Lat. and 6° 50′ W. Long. It has for its northern boundary the great desert (see Sahara in this *Supplement*), and is described by Mr Park as little better than a desert itself. Our traveller was taken captive on the confines of this kingdom, and carried to the camp of the king, where he was subjected to

Ludamar. to the cruelest indignities that the malice of bigotted Moors could invent. He was not suffered to travel beyond the camp; though he moved as it moved, and of course saw a considerable part of the country, and had an opportunity of observing the manners of the people. "The Moors of Ludamar subsist chiefly on the flesh of their cattle; and are always in the extreme of either gluttony or abstinence. In consequence of the frequent and severe fasts which their religion enjoins, and the toilsome journeys which they sometimes undertake across the desert, they are enabled to bear both hunger and thirst with surprising fortitude; but whenever opportunities occur of satisfying their appetite, they generally devour more at one meal than would serve an European for three. They pay but little attention to agriculture; purchasing their corn, cotton cloth, and other necessaries, from the Negroes, in exchange for salt, which they dig from the pits in the Great Desert.

"The natural barrenness of the country is such, that it furnishes but few materials for manufacture. The Moors, however, contrive to weave a strong cloth, with which they cover their tents; the thread is spun by their women from the hair of goats: and they prepare the hides of their cattle so as to furnish saddles, bridles, pouches, and other articles of leather. They are likewise sufficiently skilful to convert the native iron, which they procure from the Negroes, into spears and knives, and also into pots for boiling their food; but their sabres and other weapons, as well as their fire-arms and ammunition, they purchase from the Europeans, in exchange for the Negro slaves which they obtain in their predatory excursions. Their chief commerce of this kind is with the French traders on the Senegal river."

The Moors of this country have singular ideas of feminine perfection. The gracefulness of figure and motion, and a countenance enlivened by expression, are by no means essential points in their standard; with them corpulence and beauty appear to be terms nearly synonymous. A woman, of even moderate pretensions, must be one who cannot walk without a slave under each arm to support her; and a perfect beauty is a load for a camel. In consequence of this prevalent taste for unwieldiness of bulk, the Moorish ladies take great pains to acquire it early in life; and for this purpose many of the young girls are compelled by their mothers to devour an immense quantity of food, and drink a large bowl of camel's milk every morning. It is of no importance whether the girl has an appetite or not, the meat and the drink must be swallowed; and obedience is frequently enforced by blows. This singular practice, instead of producing indigestion and disease, soon covers the young lady with that degree of plumpness, which, in the eye of a Moor, is perfection itself.

"Although the wealth of the Moors consists chiefly in their numerous herds of cattle; yet, as the pastoral life does not afford full employment, the majority of the people are perfectly idle, and spend the day in trifling conversation about their horses, or in laying schemes of depredation on the Negro villages. L Lynx.

"The usual place of rendezvous for the indolent is the king's tent, where great liberty of speech seems to be exercised by the company towards each other. While in speaking of their chief, they express but one opinion. In praise of their sovereign, they are unanimous. Songs are composed in his honour, which the company frequently sing in concert; but they are so loaded with gross adulation, that no man but a Moorish despot could hear them without blushing. The king is distinguished by the fineness of his dress, which is composed of blue cotton cloth brought from Tombuctoo, or white linen or muslin from Morocco. He has likewise a larger tent than any other person, with a white cloth over it; but in his usual intercourse with his subjects, all distinctions of rank are frequently forgotten. He sometimes eats out of the same bowl with his camel driver, and reposes himself, during the heat of the day, upon the same bed.

"The military strength of Ludamar consists in cavalry. They are well mounted, and appear to be very expert in skirmishing and attacking by surprise. Every soldier furnishes his own horse, and finds his accoutrements, consisting of a large sabre, a double barrelled gun, a small red leather bag for holding his balls, and a powder horn slung over the shoulder. He has no pay, nor any remuneration but what arises from plunder. This body is not very numerous; for when Ali the king made war upon Bambara, our author was informed that his whole force did not exceed 2000 cavalry. They constitute, however, by what he could learn, but a very small proportion of his Moorish subjects. The horses are very beautiful, and so highly esteemed, that the Negro princes will sometimes give from twelve to fourteen slaves for one horse."

Cut off from all intercourse with civilized nations, and boasting an advantage over the Negroes, by possessing, though in a very limited degree, the knowledge of letters, the Moors of Ludamar are at once the vainest and proudest, and perhaps the most bigotted, ferocious, and intolerant of all the nations on the earth; combining in their character the blind superstition of the Negro with the savage cruelty and treachery of the Arab. It was with the utmost difficulty that our author made his escape from this inhospitable people.

LUPUS, the *Wolf*, a southern constellation, joined to the Centaur, containing together 19 stars in Ptolomy's catalogue, but 24 in the Britannic catalogue.

LYNX, a constellation of the northern hemisphere, composed by Hevelius out of the unformed stars. In his catalogue it consists of 19 stars, but in the Britannic 44.

M.

MACHINERY.

THE denomination *Machine* is now vulgarly given to a great variety of subjects, which have very little analogy by which they can be classed with propriety under any one name. We say a travelling machine, a bathing machine, a copying machine, a threshing machine, an electrical machine, &c. &c. The only circumstance in which all these agree seem to be, that their construction is more complex and artificial than the utensils, tools, or instruments which offer themselves to the first thoughts of uncultivated people. They are more artificial than the common cart, the bathing tub, or the flail. In the language of ancient Athens and Rome, the term was applied to every tool by which hard labour of any kind was performed; but in the language of modern Europe, it seems restricted either to such tools or instruments as are employed for executing some philosophical purpose, or of which the construction employs the simple mechanical powers in a conspicuous manner, in which their operation and energy engage the attention. An electrical machine, a centrifugal machine, are of the first class; a threshing machine, a fire machine, are of the other class. It is nearly synonymous, in our language, with ENGINE; a term altogether modern, and in some measure honourable, being bestowed only, or chiefly, on contrivances for executing work in which ingenuity and mechanical skill are manifest. Perhaps, indeed, the term *engine* is limited, by careful writers, to machines of considerable magnitude, or at least of considerable art and contrivance. We say, with propriety, steam engine, fire-engine, plating-engine, boring-engine; and a dividing machine, a copying machine, &c. Either of these terms, *machine* or *engine*, are applied with impropriety to contrivances in which some piece of work is not executed on materials which are then said to be manufactured. A travelling or bathing machine is surely a vulgarism. A machine or engine is therefore a TOOL; but of complicated construction, peculiarly fitted for expediting labour, or for performing it according to certain invariable principles: And we should add, that the dependence of its efficacy on mechanical principles must be apparent, and even conspicuous. The contrivance and erection of such works constitute the profession of the engineer; a profession which ought by no means to be confounded with that of the mechanic, the artisan, or manufacturer. It is one of the *artes liberales*; as deserving of the title as medicine, surgery, architecture, painting, or sculpture. Nay, whether we consider the importance of it to this flourishing nation, or the science that is necessary for giving eminence to the professor, it is very doubtful whether it should not take place of the three last named, and go *pari passu* with surgery and medicine. The inconsiderate reader, who peruses *Cicero de Oratore* with satisfaction, is apt to smile at Vitruvius, who requires in his architect nearly the same accomplishments which Cicero requires in his orator. He has not recollected, or perhaps did not know, that the profession of an architect in the Augustan age was the most respectable of all those which were not essentially connected with the management of state affairs. It appears that the architects were all Greeks, or the pupils of Greeks, altogether different from the members of the *Collegium Murariorum*, the corporation of builders and masons. The architecture of temples, stadiums, circuses, amphitheatres, seems to have been monopolised, by state authority, by a society which had long subsisted in Asia, connected by certain mysterious bonds, both civil and religious. We find it in Syria; and we learn that it was brought thither from Persia in very ancient times. From thence it spread into Ionia, where it became a very eminent and powerful association, under the particular protection of Bacchus, to whom the members had erected a magnificent temple at Teos, with a vast establishment of priests and priestesses, consisting of persons of the first rank in the state. They were the sole builders of temples and stadiums throughout all Greece and the Lesser Asia; and the contractors for the machinery that was employed in the theatres, and in the great temples, for the celebration of the high mysteries of paganism. By the imperfect accounts which remain of the Eleusinian and other mysteries, it appears, that this machinery must have been immense and wonderful, and must have required a great deal of mechanical skill. This indeed appears, in the most convincing manner, to any person who reflects on the magnificent structures which they erected, which excite to this day the wonder of the world, not only on account of their magnificence and incomparable elegance, but also on account of the mechanical knowledge that seems indispensably necessary for their erection. This will ever remain a mystery. There are no traces of such knowledge to be found in the writings of antiquity. Even Vitruvius, writing expressly on the subject, has given us nothing but what is in the lowest degree of elementary knowledge.

This association of the Dyonisiacs undoubtedly kept their mechanical science a profound secret from the uninitiated, the profane. They were the engineers of antiquity, and Vitruvius was perhaps not one of the initiated. He speaks of Myro and other Greek architects in terms of respect which border on veneration. Perhaps the modern association of free masons is a remain of this antient fraternity, continued to our times by the company of builders, who erected the cathedrals and great conventual churches. No one who considers their works with scientific attention, can doubt of their being deeply versed in the principles of mechanics, and even its more refined branches. They appear to have carried the art of vault-roofing almost to its acmé of perfection; far outstripping their Grecian instructors in their knowledge of this most delicate branch of their art.

It were greatly to be wished that some such institution did yet exist, where men might be induced by the most powerful motives to accomplish themselves in the knowledge necessary for attaining eminence in their profession.

We have been informed (and we thought our authority good), that our gracious Sovereign has signified his intention of patronising an institution of this kind. We heard, that it was proposed to institute degrees similar to our university degrees, and proceeding on similar conditions of a regular education or standing, which would ensure the *opportunities* of information, and also on an examination of the proficiency of the candidate. This examination, being conducted by persons eminent in the profession, perhaps still exercising it, would probably be serious, because the successful candidate would immediately become a rival practitioner. Such an institution would undoubtedly prevent many gross impositions by unlettered mill-wrights and pump-makers, who now seldom appear under any name but that of engineer, although they are frequently ignorant even of the elements of mechanical science, and are totally unacquainted with the higher mathematics; without which it is absolutely impossible for them to contrive a machine well suited to the intended purpose, or to say with any tolerable precision what will be the performance of the engine they have erected. Yet these are questions susceptible of accurate solution, because they depend on the unalterable laws of matter and motion.

All who have a just view of the unspeakable advantages which this highly favoured land possesses in the superiority and activity of its manufactures, and who know how much of this superiority should be ascribed to the great improvements which have been made in practical mechanics within these last thirty years, will join us in wishing success to some such institution as that now mentioned.

We were naturally led to these reflections when we turned our thoughts to machinery in general, and observed what is done in this country by the native energy of its inhabitants, unassisted by such scientific instructions as they might have expected from the pupils of a Newton, their countryman, under the patronage of the best of Sovereigns, eminently knowing in these things, and ever ready to encourage those sciences and arts which have so highly contributed to the national prosperity. What might not be reasonably expected from British activity, if those among ourselves who have knowledge and leisure had been at the same pains with the members of the foreign academies to cultivate the Newtonian philosophy, and particularly the more refined branches of mechanics, and to deduce from their speculations maxims of construction fitted to our situation as a great manufacturing nation? But such knowledge is not attainable by those who are acquainted only with the imperfect elements contained in the publications read by the bulk of our practitioners. Much to this purpose has been done on the continent by the most eminent mathematicians; but from want of individual energy, or perhaps of general security and protection, the patriotic labours of those gentlemen have not done the service to their country which might have been reasonably expected. Indeed, their dissertations have generally been so composed, that only the learned could see their value. They seem addressed only, or chiefly, to such; but it is to those authors that our countrymen generally have recourse for information concerning every thing in their profession that rises above mere elementary knowledge. The books in our language which profess to be systems of mechanics rarely go beyond this: they contain only the principles of equilibrium. These are absolutely necessary for the knowledge of machines; but they are very far indeed from giving what may be called a practical knowledge of *working machinery*. This is never in a state of equilibrium. The machine must move in order to work. There must be a superiority of impelling power, beyond what is merely sufficient for balancing the resistance or contrary action of the work to be performed. The reader may turn to the article STATICS in the *Encyclopædia Britannica*, and he will there see some farther observations on this head. And in the article MECHANICS he will find a pretty ample detail of all the usual doctrines, and a description of a considerable variety of machines or engines, accompanied by such observations as are necessary for tracing the propagation or transmission of pressure from that part of the machine to which the natural power is applied to the working part of the machine. Along with these two articles, it will be proper to read with peculiar attention the article ROTATION.

By far the greatest number of our most serviceable engines consist chiefly of parts which have a motion of rotation round fixed axes, and derive all their energy from levers virtually contained in them. And these acting parts are also material, requiring force to move them, over and above what is necessary for producing the acting force at the working part of the machine. The modifications which this circumstance frequently makes of the whole motions of the machine, are indicated in the article ROTATION in an elementary way; and the propositions there investigated will be found almost continually involved in the complete theory of the operation of a machine. Lastly, it will be proper to consider attentively the propositions contained in the article *Strength of Materials*, that we may combine them with those which relate wholly to the working of the machine; because it is from this combination only that we discover the strains which are excited at the various points of support, and of communication, and in every member of the machine. We suppose all these things already understood.

Our object at present is to point out the principles which enable us to ascertain what will be the precise motion of a machine of given construction, when actuated by a natural power of known intensity, applied to a given point of the machine, while it is employed to overcome a known resistance acting at another point. To abbreviate language, we shall call that the IMPELLED POINT of the machine to which the pressure of the moving power is immediately applied; and we may call that the WORKING POINT, where the resistance arising from the work to be performed immediately acts. The chief question in mechanics.

To consider this important subject, even in its chief varieties, requires much more room than can be allowed in an undertaking like ours, and therefore we must content ourselves with a very limited view; but at the same time, such a view as shall give sufficient indication of the principles which should direct the practical reader in every important case. We shall consider those machines which

which perform their motions round fixed axes; these being by far the most numerous and important, because they involve in their construction and operations all the leading principles.

2 The proper measure of mechanical power exerted.

That we may proceed securely, it is necessary to have a precise and adequate notion of moving force, as applied to machinery, and of its measures. We think this peculiarly necessary. Different notions have been entertained on this subject by Mr Leibnitz, Des Cartes, and other eminent mechanicians of the last century; and their successors have not yet come to an agreement. Nay, some of the most eminent practitioners of the present times (for we must include Mr Smeaton in the number) have given measures of mechanical power in machinery which we think inaccurate, and tending to erroneous conclusions and maxims.

We take for the measure (as it is the effect) of exerted mechanical power the quantity of motion which it produces by its uniform exertion during some given time. We say *uniform exertion*, not because this uniformity is necessary, but only because, if any variation of the exertion has taken place, it must be known, in order to judge of the power. This would needlessly complicate the calculations; but in whatever way the exertion may have varied, the whole accumulated exertion is still accurately measured by the quantity of motion existing at the end of the exertion. The reader must perceive that this is the same thing that is expressed in the article DYNAMICS of this *Supplement*, n° 90. by the area of the figure whose abscissa or axis represents the time of exertion; and the ordinates are as the pressures in the different instants of that time, the whole being multiplied by the number of particles (that is, by the quantity of matter), because that figure represents the quantity of motion generated in one particle of matter only. All this is abundantly clear to persons conversant in these disquisitions; but we wish to carry along with us the distinct conceptions of that useful class of readers whose profession engages them in the construction and employment of machines, and to whom such discussions are not so familiar. We must endeavour therefore to justify our choice of this measure by appealing to familiar facts.

If a man, by pressing uniformly on a mass of matter for five seconds, generates in it the velocity of eight feet per second, we obtain an exact notion of the proportion of this exertion to the mechanical exertion of gravity, when we say that the man's exerted force has been precisely one-twentieth part of the action of gravity on it; for we know that the weight of that body (or, more properly, its heaviness) would, in five seconds, have given it the velocity of 160 feet per second, by acting on it during its fall. But let us attend more closely to what we mean by saying that the exerted force is one-twentieth of the exertion of gravity. The only notion we have of the exertion of gravity is what we call the weight of the body—the pressure which we feel it make on our hand. To say that this is 20 pounds weight, does not explain it; because this is only the action of gravity on another piece of matter. Both pressures are the same. But if the body weighs 20 pounds, it will draw out the rod of a steelyard to the mark 20. The rod is so divided, that the 20th part of this pressure will draw it out to 1. Now the fact is, that if the man presses on the mass of 20 pounds weight with a spring steelyard during five seconds, and if during that time the rod of the steelyard was always at the mark 1, the body will have acquired the velocity of eight feet per second. This is an acknowledged fact. Therefore we were right in saying, that the man's exertion is one-twentieth of the exertion of gravity. And since we believe the weight of bodies to be proportional to their quantity of matter, all matter being equally heavy, we may say, that the man's exertion was equal to the action of gravity on a quantity of matter whose weight is one pound. We express it much more familiarly, by saying, that the man exerted on it the pressure of one pound of matter, or the force of one pound.

In this manner, the motion communicated to a mass of matter, by acting on it during some time, informs us with accuracy of the real mechanical force or pressure which has been exerted. This is judged to be double when twice the velocity has been generated in the same mass, or where the same velocity has been generated in twice the mass; because we know, that a double pressure would have done either the one or the other.

But farther: We know that this pressure is the exertion; we have no other notion of our own force; and our notion of gravity, of elasticity, or any other natural force, is the same. We also know that the continuance of this exertion fatigues and exhausts our strength as completely as the most violent motion. A dead pull, as it is called, of a horse, at a post fixed in the ground, is a usual trial of his strength. No man can hold out his arm horizontally for much more than a quarter of an hour; and the exertion of the last minutes gives the most distressing fatigue, and disables the shoulder from action for a considerable time after. This is therefore an expenditure of mechanical power, in the strict primitive sense of the word. Of this expenditure we have an exact and adequate effect and measure in the quantity of motion produced; that is, in the product of the quantity of matter by the velocity generated in it by this exertion. And it must be particularly noticed, that this measure is applicable even to cases where no motion is produced by the exertion; that is, if we know that the exertion which is just unable to start a block of stone lying on a smooth stone pavement, but would start it, if increased by the smallest addition; and if we know that this would generate in a second 32 feet of velocity in 100 pounds of matter—we are certain that it was a pressure equal to the weight of this 100 pounds. It is a good measure, though not immediate, and may be used without danger of mistake when we have no other.

The celebrated engineer Mr Smeaton, in his excellent dissertation on the power of water and wind to drive machinery, and also in two other dissertations, all published in the Philosophical Transactions, and afterwards in a little volume, has employed another measure, both of the expenditure of mechanical power, and of the mechanical effect produced. He says, that the weight of a body, multiplied by the height thro' which it descends, while driving a machine, is the only proper measure of the power expended; and that the weight, multiplied by the height through which it is uniformly raised, is the only proper measure of the effect produced. And he produces a large train of accurate experiments

3 Mr Smeaton's measure

riments to prove that a certain weight, descending through a certain space, always produces the same effect, whether it has descended swiftly or slowly, employing little or much time.

Had this eminent engineer proposed this as a popular measure, of easy comprehension and remembrance, and as well accommodated to the uses of those engaged in the construction of machines, when restricted to a certain class of cases, it might have answered very good purposes; but the author is at pains to recommend it to the philosophers as a necessary correction of their theories, which he says tend to mislead the artists. His own reasonings terminate in the same conclusion with Mr Leibnitz's, namely, that the power of producing a mechanical effect, and the effect produced, are proportional to the square of the velocity. The deference justly due to Mr Smeaton's authority, and the influence of his name among those who are likely to make the most use of his instructions, render it necessary for us to examine this matter with some attention.

Mr Smeaton was led to the adoption of this measure by his professional habits. Raising a weight to a height is, in one shape or another, the general task of the machines he was employed to erect; and we may add, the opportunities of expending the mechanical powers of nature which are in our command, are generally in this proportion. A certain daily supply of water, coming from a certain height, is our best opportunity, and may very properly be said to be expended.

[4] zamined,

This being the general case, the measure was obvious, and natural, and good. The power and effect were of the same kind, and *must* be measures of each other; at least, in those circumstances in which they were set in op[position]. Yet even here Mr Smeaton was obliged to [mak]e a restriction of his measures. "The height thro' which a body *slowly and equably* descended, or to which it was raised." And why was this limitation necessary? "Because in rapid or accelerated motions, the inertia of bodies occasioned some variation*." But this is too vague language for philosophical disquisition. Besides, what is meant by this variation? What is the standard from which the unrestricted measure varies? This standard, whatever it is, is the true measure, and it was needless to adopt any other. Now, the standard from which Mr Smeaton estimates the deviation, is the very measure which we wish to employ, namely, the quantity of motion produced. Strictly speaking, even this is not the immediate measure. The immediate measure is that faculty which we call pressure. This is the intermedium perceivable in all productions of motion; and it is also the intermedium of mechanical effect, even when motion is not produced; as when the weight of a body bends a spring, or the elasticity of a body supports another pressure. How it operates in all or any of these cases, we know not: but we know that all these measures of pressure agree with each other. A double quantity of motion will bend a spring doubly strong, will raise a double weight, will withstand any double pressure, &c &c. In short, pressure is the immediate agent in every mechanical phenomenon. It penetrates bodies, overcoming their tenacity; it overcomes friction; it balances pressure; it produces motion. Mr Smeaton's measure is only nearly true, in any case, and in all cases it is far from being exact in the first instants of the motion, during its acceleration or retardation.

* Page 7.

We have already noticed the complete expenditure of animal power by continued pressure, even when motion is not produced: the only difficulty is to connect this in a measurable way with the power which the same exertion has of generating motion in a body.

When a man supports a weight for a single instant, he certainly balances the pressure or action of gravity on that body; and he continues this action as long as he continues to support it: and we know that if this body were at the end of a horizontal arm turning round a vertical axis, the same effort which the man exerted in merely carrying the weight, if now exerted on the body, by pushing it horizontally round the axis, will generate in it the same velocity which gravity would generate by its falling freely. On this authority therefore we say, that the whole accumulated action of a man, when he has just carried a body whose weight is 30 pounds for one minute, is equal to the whole exertion of gravity on it during that minute; and if employed, not to counteract gravity, but to generate motion, would generate, during that minute, the same motion that gravity would, that is, 60 × 32 feet velocity per second, in a mass of 30 pounds. There would be 30 pounds of matter moving with the velocity of 1920 feet per second. We would express this production or effect by 30 × 1920, or by 57600, as the measure of the man's exertion during the minute.

But, according to Mr Smeaton, there is no expenditure of power, nor any production of mechanical effect, in thus carrying 30 pounds for a minute; there is no product of a weight by a height through which it is equably raised; yet such exertion will completely exhaust a man's strength if the body be heavy enough. Here then is a case to which Mr Smeaton's measure does not readily apply; and this case is important including all the actions of animals at a dead pull.

But let us consider more narrowly what a man really does when he performs what Mr Smeaton allows to be the production of a measurable mechanical effect. Suppose this weight of 30 pounds hanging by a cord which passes over a pulley, and that a man, taking this cord over his shoulder, turns his back to the pulley, and walks away from it. We know, that a man of ordinary force will walk along, raising this weight, at the rate of about 60 yards in a minute, or a yard every second, and that he can continue to do this for eight or ten hours from day to day; and that this is all that he can do without fatigue. Here are 30 pounds raised uniformly 180 feet in a minute; and Mr Smeaton would express this by 30 × 180, or 5400, and would call this the measure of the mechanical effect, and also of the expenditure of power. This is very different from our measure 57600.

But this is not an accurate and complete account of the man's *action* on the weight, and of the whole effect produced. To be convinced of this, suppose that a man A has been thus employed, while another B, walking along side of him at the same rate, suddenly takes the rope out of his hand, frees him of the task, and *continues* to raise the weight without the smallest change on its velocity of ascent. What is the action of B, and whether is it the same with that of A or not? It is acknowledged by all, that the exertion of B against the load is precisely equal to 30 pounds. If he holds the rope by a spring steelyard, it will stand constantly at the mark 30. B exerts the same action on the load as when

[5] And found to be inaccurate.

when he firmly supports it from falling back into the pit. It was moving with the velocity of three feet per second when he took hold of the rope, and it would continue to move with that velocity if any thing could annihilate or counteract its gravity. If therefore there was no action when a person merely carried it, there is none at present when it is rising 180 feet in a minute. The man does indeed work more than on that occasion, but not against the load: his additional work is walking, the motion of his own body, as a thing previously necessary that he may continue to support the load, that he may continue his mechanical effort as it follows him. It appears to yield to him: but it is not to *his* efforts that it yields; its weight completely balances those efforts, and is balanced by them. It was to a *greater* effort of the man A that it yielded. It was then lying on the ground. He pulled at the cord, gradually perhaps increasing his pull till it was just equal to its weight. When this obtains, the load no longer presses on the ground, but is completely carried by the rope. But it does not move by this effort of 30 pounds; but let him exert a force of 31 pounds, and continue this for three seconds. He will put it in motion; will accelerate that motion; and at the end of three seconds the load is rising with the velocity of three feet per second. The man feels that this is as much speed as he can continue in his walk; he therefore slackens his pull, reducing his action to 30 pounds, and with this action he walks on. All this would be distinctly perceived by means of a steelyard. The rod would be pulled out beyond 30, till the load acquired the uniform velocity intended, and after this it would be observed to shrink back to 30.

More is done therefore than appears by Mr Smeaton's measure. Indeed, all that appears in it is the exertion necessary for *continuing* a motion already produced, but which would be immediately extinguished by a contrary power, which must therefore be counteracted. This measure will not apply to numberless cases of the employment of machines, where there is no such opposing power, and where, notwithstanding, mechanical power must be expended, even according to Mr Smeaton's measurement. Such are corn mills, boring mills, and many others.

How then comes it that Mr Smeaton's valuable experiments concur so exactly in shewing that the same quantity of water descending from the same height, always produces the same effect (as he measured it), whatever be the velocity? In the first place, all his experiments are cases where the power expended and the work performed are of the same kind: A heavy body descends, and by its preponderancy raises another heavy body. But even this would not ensure the precise agreement observed in his experiments, if Mr Smeaton were not careful to exclude from his calculations all that motion where there is any acceleration, and all the expenditure of water during the acceleration, and to admit only those motions that are sensibly uniform. In moderate velocities, the additional pressure required for the first acceleration is but an insignificant part of the whole; and to take these accelerated motions into the account, would have embarrassed the calculations, and perhaps confused many of the readers. We see, in the instance now given, that the addition of one pound continued for three seconds only, was all that was necessary.

Mr Smeaton's measurement is therefore abundantly exact for practice; and being accommodated to the circumstances most likely to engage the attention, is very proper for the instruction of the numerous practitioners in all manufacturing countries who are employed for ordinary erections: but it is improperly proposed as an article essential to a just theory of mechanics, and therefore it was proper to notice it in this place. Besides, there frequently occur most important cases, in which the motion of a machine is, of necessity, desultory, alternately accelerated, and retarded. We should not derive all the advantages in our power from the first mover, if we did not attend particularly, and chiefly, to the *accelerating* forces. And in every case, the improvement, or the proper employment of the machine, is not attained, if we are not able to discriminate between the two parts of the mechanical exertion; one of them, by which the motion is produced and accelerated to a certain degree; and the other, by which that motion is continued. We must be able to appreciate what part of the effect belongs to each.—But it is now time to proceed to the important question,

What will be the precise motion of a machine of given construction, actuated by a power of known intensity and manner of acting, and opposed by a known resistance?

In the solution of this question, much depends on the nature of both power and resistance. In the statical consideration of machines, no attention is paid to any differences. The intensity of the pressures is all that it is necessary to regard, in order to state the proportion of pressure which will be exerted in the various parts of the machine. The pressures at the impelled and working points, combined with the proportions of the machine, necessarily determine all the rest. Pressure being the sole cause of all mechanical action among bodies, any pressure may be substituted for another that is equal to it; and the pressure which is most familiar, or of easiest consideration, may be used as the representative of all others. This has occasioned the mechanical writers to make use of the pressure of gravity as the standard of comparison, and to represent all powers and resistances by weights. However proper this may be in their hands, it has hurt the progress of the science. It has rendered the usual elementary treatises of mechanics very imperfect, by limiting the experiments and illustrations to such as can be so represented with facility. This has limited them to the state of equilibrium (in which condition a working machine is never found), because illustrations by experiment out of this state are neither obvious nor easy. It has also prevented the students of mechanics from accomplishing themselves with the mathematical knowledge required for a successful prosecution of the study. The most elementary geometry is sufficient for a thorough understanding of equilibrium, or the doctrines of statics; but true mechanics, the knowledge of machines as instruments by which work is performed, requires more refined mathematics, and is inaccessible without it.

Things to be considered in a machine at work.

Had not Newton or others improved mathematics by the invention of the infinitesimal analysis and calculus, we must have rested contented with the discoveries (really great) of Galileo and Huyghens. But Newton,

ton, *sui mathesi facem præferente*, opened a boundless field of investigation, and has not only given a magnificent and brilliant specimen of the discoveries to be made in it, but has also traced out the particular paths in which we are to find the solution of all questions of practical mechanics. This he has done by shewing another species of equilibrium, indicated, not by the cessation of all motion, but by the uniformity of motion; by the cessation of all acceleration or retardation. As the extinction of motion by the action of opposite forces is assumed by us as the indication of the perfect equality of those forces; so the extinction of acceleration should be received as the indication of something equal and opposite to the force which was known to have caused the acceleration; and therefore as the indication of an equilibrium between opposite forces, or else of the cessation of all force.

7 Mechanical equilibrium. This new view of things was the source of all our distinct notions of mechanical forces, and gave us our only unexceptionable marks and measures of them. The 39th proposition of the first book of Newton's Principles of Natural Philosophy, and its corollaries, contain almost the whole doctrine of active mechanical nature, and are peculiarly applicable to our present purpose, because they enable us to comprehend in this *mechanical equilibrium* (so different from the *statical*) every circumstance in which those pressures which are exerted by natural powers differ from each other, and vary in their action on the impelled and working points of a machine. Indeed, when we recollect that the operations of our machines are the same on board a ship as on shore, and that all our machines are moving with the ground on which they stand, we must acknowledge, that even ordinary statics is only an imperfect view of an equilibrium among things which are in motion; and this should have taught us that, even in those cases where nothing like equilibrium appears, an equilibrium may still be usefully traced.

8 Distinctions must be made in the nature of the powers applied to working machines. In the statical consideration of machines, the *quantity* of pressure is all that we need attend to. But in the mechanical discussion of their *operations*, we must attend to their distinctions in kind; and it will by no means be sufficient to represent them all by weights; for their distinction in kind is accompanied by great differences in their manner of acting on the machine. Some natural powers, in order to continue their action on the impelled point of the machine, must at the same time put into motion a quantity of matter external to the machine, in which these powers reside; and this must be made to follow the impelled point in its motion, and not only follow, but continue to press it forward; or, this matter, thus continually put into motion, must be successively applied to different points of the machine, which become impelled points in their turn. This is the case with a weight, with the action of a spring, the action of animals, the action of a stream of water or wind, and many other powers. A part of the natural mechanical powers must therefore be employed in producing this external motion. This is sometimes a very considerable part of the whole natural power. In some cases it is the whole of it. This obtains in the action of a descending weight, lying on the end of a lever and pressing it down, or hanging by a chord attached to the machine.

There is also an important distinction in the manner in which this external motion is kept up. In a weight employed as the moving power, the actuating pressure seems to reside in the matter itself; and all that is necessary for continuing this pressure is merely to continue the connection of it with the machine. But in the action of animals it may be very different: A man pushing at a capstan bar, must first of all walk as fast as the bar moves round, and this requires the expenditure of his muscular force. But this alone will not render his action an effective power: He must also *press forward* the capstan bar with as much force as he has remaining over and above what he expends in walking at that rate. The proportion of these two expenditures may be very different in different circumstances; and in the judicious selection of such circumstances as make the first of these as inconsiderable as possible, lies much of the skill and sagacity of the engineer. In the common operation of thrashing corn, much more than half of the man's power is expended in giving the necessary motion to his own body, and only the remainder is employed in urging forward the swiple with a momentum sufficient for shaking off the ripe grains from the stalk. We had sufficient proof of this, by taking off the swiple of the flail, and putting the same weight of lead on the end of the staff, and then causing the hind to perform the usual motions of thrashing with all the rapidity that he could continue during the ordinary hours of work. We never could find a man who could make three motions in the same time that he could make two in the usual manner, so as to continue this for half an hour. Hence we must conclude, that half (some will say two thirds) of a thrasher's power is expended in merely moving his own body. Such modes of animal action will therefore be avoided by a judicious engineer; but to be avoided, their inconvenience must be understood. More of this will occur hereafter.—In other cases, we are almost (never wholly) free from this unprofitable expenditure of power. Thus, in the steam engine, the operation requires that the external air follow the piston down the cylinder, in order to continue its pressure. But the force necessary for sending in this rare fluid into the cylinder with the necessary velocity, is such an insignificant part of the whole force which is at our command, that it would be ridiculous affectation in any engineer to take it into account; and this is one great ground of preference to this natural power. The same thing may be said of the action of a strong and light spring, which is therefore another very eligible first mover for machinery. The ancient artillerists had discovered this, and employed it in their warlike engines.

We must also attend to the nature of the resistance which the work to be performed opposes to the motion of our machine. Sometimes the work opposes, not a simple obstruction, but a real resistance or reaction, which, if applied alone to the machine, would cause it to move the contrary way. This always obtains in cases where a heavy body is to be raised, where a spring is to be compressed, and in some other cases. Very often, however, there is no such contrary action. A flour mill, a saw mill, a boring mill, and many such engines, exhibit no reaction of this kind. But although such machines, when at rest or not impelled by the first mover, sustain no pressure in the opposite direction, yet they

they will not acquire any motion whatever, unless they be impelled by a force of a certain determinate intensity. Thus in a saw mill, a certain force must be impressed on the teeth of the saw, that the cohesion of the fibres of the timber may be overcome. This requires that a certain force, determined by the proportions of the machine, be impressed on the impelled point. If this, and no more, be applied there, a force will be excited at the teeth of the saw, which will *balance* the cohesion of the wood, but will not *overcome* it. The machine will continue at rest, and no work will be performed. Any addition of force at the impelled point, will occasion an addition to the force excited in the teeth of the saw. The cohesion will be overcome, the machine will move, and work will be performed. It is only this *addition* to the impelling power that gives motion to the machine; the rest being expended merely in balancing the cohesion of the woody fibres. While therefore the machine is in motion, performing work, we must consider it as actuated by a force impressed on the impelled point by the natural power, and by another acting at the working point, furnished by or derived from the resistance of the work.

Again: It not unfrequently happens, that there is not even any such resistance or obstruction excited at the working point of the machine; the whole resistance (if we can with propriety give it that name) arises from the necessity of giving motion to a quantity of inert and inactive matter. This happens in urging round a heavy fly, as in the coining press, in the punching engine, in drawing a body along a horizontal plane without friction, and a few similar cases. Here the smallest force whatever, applied at the impelled point, will begin motion in the machine; and the *whole* force so applied is consumed in this service. Such cases are rare, as the ultimate performance of a machine; but occasionally, and for a farther purpose, they frequently occur; and it is necessary to consider them, because there are many of the most important applications of machinery where a very considerable part of the force is expended in this part of the general task.

Such are the chief circumstances of distinction among the mechanical powers of nature which must be attended to, in order to know the motion and performance of a machine. These never occur in the statical consideration of the machine, but here they are of chief importance.

9 The iner[illegible] of the m[illegible] [illegible] be con[illegible]si-dered,

But farther: The action of the moving power is transferred to the working point through the parts of a machine, which are material, inert, and heavy. Or, to describe it more accurately, before the necessary force can be excited at the working point of the machine, the various connecting forces must be exerted in the different parts of the machine; and in order that the working point may follow out the impression already made, all the connecting parts or limbs of the machine must *be moved*, in different directions, and with different velocities. Force is necessary for thus changing the state of all this matter, and frequently a very considerable force. Time must also elapse before all this can be accomplished. This often consumes, and really wastes, a great part of the impelling power. Thus, in a crane worked by men walking in a wheel, it acquires motion by slow degrees; because, in order to give sufficient room for the action of the number of men or cattle that are necessary, a very capacious wheel must be employed, containing a great quantity of inert matter. All of this must be put in motion by a very moderate preponderance of the men. It accelerates slowly, and the load is raised. When it has attained the required height, all this matter, now in considerable motion, must be stopped. This cannot be done in an instant with a jolt, which would be very inconvenient, and even hurtful; it is therefore brought to rest gradually. This also consumes time; nay, the wheel must get a motion in the contrary direction, that the load may be lowered into the cart or lighter. This can only be accomplished by degrees. Then the tackle must be lowered down again for another load, which also must be done gradually. All this wastes a great deal both of time and of force, and renders a walking wheel a very improper form for the first mover of a crane, or any machine whose use requires such frequent changes of motion. The same thing obtains, although in a lower degree, in the steam engine, where the great beam and pump rods, sometimes weighing very many tons, must be made to acquire a very brisk motion in opposite directions twice in every working stroke. It obtains, in a greater or a less degree, in all engines which have a reciprocating motion in any of their parts. Pump mills are of necessity subjected to this inconvenience. In the famous engine at Marly, about [illegible] of the whole moving power of some of the water wheels is employed in giving a reciprocating motion to a set of rods and chains, which extend from the wheels to a cistern about three-fourths of a mile distant, where they work a set of pumps. This engine is, by such injudicious construction, a monument of magnificence, and the struggle of ignorance with the unchangeable laws of Nature. In machines, all the parts of which continue the direction of their motions unchanged, the inertia of a great mass of matter does no harm; but, on the contrary, contributes to the steadiness of the motion, in spite of small inequalities of power or resistance, or unavoidable irregularities of force in the interior parts. But in all reciprocations, it is highly prejudicial to the performance; and therefore constructions which admit such reciprocation without necessity, are avoided by all intelligent engineers. The mere copying artist, indeed, who derives all his knowledge from the common treatises of mechanics, will never suspect such imperfections, because they do not occur in the statical consideration of machines.

10 And its friction.

Lastly, no machine can move without a mutual rubbing of its parts, at all points of communication; such as the teeth of wheelwork, the wipers and lifts, and the gudgeons of its different axes. In many machines, the ultimate task performed by the working point, is either friction, or very much resembles it. This is the case in polishing mills, grinding mills, nay in boring mills, saw mills, and others. A knowledge of friction, in all its varieties, seems therefore absolutely necessary, even for a moderate acquaintance with the principles of machinery. This is a very abstruse subject; and although a good deal of attention has been paid to it by some ingenious men, we do not think that a great deal has been added to our knowledge of it; nor do the experiments which have been made seem to us well calculated to lead us to a distinct knowledge of its nature and modifications. It has been considered chiefly with a view to diminish it as much as possible in the communicating parts

parts of machinery, and to obtain some general rules for ascertaining the quantity of what unavoidably remains. Mr Amontons, of the Royal Academy of Sciences at Paris, gave us, about the beginning of this century, the chief information that we have on the subject. He discovered, that the obstruction which it gave to motion was very nearly proportional to the force by which the rubbing surfaces are pressed together. Thus he found, that a smooth oaken board, laid on another smooth board of the same wood, requires a force nearly equal to one third of what presses the surfaces together. Different substances required different proportions.

Measure of it by Amontons.

He also found, that neither the extent of the rubbing surfaces, nor the velocity of the motion, made any considerable variation on the obstruction to motion. These were curious and unexpected results. Subsequent observations have made several corrections necessary in all these propositions. This subject will be more particularly considered in another place; but since the deviations from Mr Amontons's rule are not very considerable, at least in the cases which occur in this general consideration of machines, we shall make use of it in the mean time. It gives us a very easy method of estimating the effect of friction on machines. It is a certain proportion of the mutual pressure of the rubbing surfaces, and therefore must vary in the same proportion with this pressure. Now, we learn from the principles of statics, that whatever pressures are exerted on the impelled and working point of the machine, all the pressures on its different parts have the same constant proportion to these, and vary as these vary. Therefore the whole friction of the machine varies in the same proportion. But farther, since it is found that the friction does not sensibly change with the velocity, the force which is just sufficient to overcome the friction, and put the loaded machine in motion, must be very nearly the same with the force expended in overcoming the friction while the machine is moving with any velocity whatever, and performing work. Therefore if we deduct from the force which just puts the loaded machine in motion that part of it which balances the reaction of the impelled point occasioned by the resistance of the work, or which balances the resistance of the work, the remainder is the part of the impelling power which is employed in overcoming the friction. If indeed the actual resisting pressure of the work varies with the velocity of the working point, all the pressures, and all the frictions in the different communicating parts of the machine, vary in the same proportion. But the law of this variation of working resistance being known, the friction is again ascertained.

We can now state the dynamical equilibrium of forces in the working machine in two ways. We may either consider the efficient impelling power as diminished by all that portion which is expended in overcoming the friction, and which only prepares the machine for performing work, or we may consider the impelling power as entire, and the work as increased by the friction of the machine; that is, we may suppose the machine without friction, and that it is loaded with a quantity of additional resistance acting at the working point. Either of these methods will give the same result, and each has its advantages. We took the last method in the slight view which we took of this subject in the *Encycl.* art. ROTATION, n° 64. and shall therefore use it here.

Supposing now this previous knowledge of all these variable circumstances which affect the motion of machines of the rotative kind, so that, for any momentary position of it while performing work, we know what are the precise pressures acting at the impelled and working points, and the construction of the machine, on which depend the friction, and the momentum of its inertia (expressed in the article ROTATION by $\int p r^2$); we are now in a condition to determine its motion, or at least its momentary acceleration, competent to that position. Therefore,

14 Composition of the formula expressing the performance of a machine.

Let there be a rotative machine, so constructed, that while it is performing work, the velocity of its impelled point is to that of its working point as m to n. It is easy to demonstrate, from the common principles of statics, that if a simple wheel and axle be substituted for it, having the radius of the wheel to that of the axle in the same proportion of m to n, and having the same momentum of friction and inertia, and actuated by the same pressures at the impelled and working points, then the velocities of these points will be precisely the same as in the given machine.

Let p represent the intensity (which may be measured by pounds weight) of the pressure exerted in the moment at the impelled point; and r express the pressure exerted at the working point by the resistance opposed by the work that is then performing. This may arise from the weight of a body to be raised, from the cohesion of timber to be sawed, &c. Any of these resistances may also be measured by pounds weight; because we know, that a certain number of pounds hung on the saw of a saw mill, will just overcome this cohesion, or overcome it with any degree of superiority. Therefore the impelling power p, and the resistance r, however differing in kind, may be compared as mere pressures.

Let x represent the quantity of inert matter which must be urged by the impelling power p, with the same velocity as the impelled point, in order that this pressure p may really continue to be exerted on that point. Thus, if the impelling power is a quantity of water in the bucket of an overshot wheel, acting by its weight, this weight cannot impel the wheel except by impelling the water. In this way, x may be considered as representing the inertia of the impelling power, while p represents its pressure on the machine. In like manner, let y represent the quantity of external inert matter which is really moved with the velocity of the working point in the execution of the task performed by the machine.

Whatever be the momentum of the inertia of the machine, we can always ascertain what quantity of matter, attached to the impelled point, or the working point of the wheel and axle, will require the same force to give the wheel the same angular motion; that is, which shall have the same momentum of inertia. Let the quantity a, attached to the working point, give this momentum of inertia $a n^2$.

Lastly, supposing that the wheel and axle have no friction, let f be such a resistance, that if applied to the working point, it shall give the same obstruction as the friction of the machine, or require the same force at the impelled point to overcome it.

These

13 Angular motion of the machine.

These things being thus established, the angular velocity of the wheel and axle, that is, the number of turns, or the portion of a turn, which it will make in a given time, will be proportional to the fraction $\frac{pm - \overline{r+f}n}{xm^2 + \overline{a+y}n^2}$. (I.)—See ROTATION, n° 64, &c. *Encycl.*

Since the whole turns together, the velocities of the different points are as their distances from the axis, and may be expressed by multiplying the common angular velocity by these distances. Therefore the above formula, multiplied by m or n, will give the velocity of the impelled or of the working point. Therefore,

14 Velocity of the impelled point.

$$\text{Velocity of impelled point} = \frac{pm^2 - \overline{r+f}mn}{xm^2 + \overline{a+y}n^2}. \text{ (II.)}$$

15 Velocity of the working point.

$$\text{Velocity of working point} = \frac{pmn - \overline{r+f}n^2}{xm^2 + \overline{a+y}n^2}. \text{ (III.)}$$

In order to obtain a clear conception of these velocities, we must compare them with motions with which we are well acquainted. The proposition being universally true, we may take a case where gravity is the sole power and resistance; where, for example, p and r are the weights of the water in the bucket of a wheel, and in the tub that is raised by it. In this case, $p = x$, and $r = y$. We may also, for greater simplicity, suppose the machine without inertia and friction. The velocity of p is now $\frac{pm^2 - rmn}{pm^2 + rn^2}$.

16 Absolute measure of them.

Let g be the velocity which gravity generates in a second. Then it will generate the velocity $g\dot{t}$ in the moment $\dot{t}$. Let $\dot{v}$ be the velocity generated during this moment in p, connected as it is with the wheel and axle, and with r. This connection produces a change of condition $= g\dot{t} - \dot{v}$. For, had it fallen freely, it would have acquired the velocity $g\dot{t}$, whereas it only acquires the velocity $\dot{v}$. In like manner, had r fallen freely, it would have acquired the velocity $g\dot{t}$. But, instead of this, it is raised with the velocity $\frac{n}{m}\dot{v}$. The change on it is therefore $= g\dot{t} + \frac{n}{m}\dot{v}$. These changes of mechanical condition arise from their connection with the corporeal machine Their pressures on it bring into action its connecting forces, and each of the two external forces is in immediate equilibrium with the force exerted by the other. The force excited at the impelled point, by r acting at the working point, may be called the momentum or energy of r. These energies are precisely competent to the production of the changes which they really produce, and must therefore be conceived as having the same proportions. They are therefore equal and opposite, by the general laws *observed* in all actions of tangible matter; that is, they are such as balance each other. Thus, and only thus, the remaining motions are what we observe them to be.

$$\text{That is, } p \times \overline{g\dot{t} - \dot{v}} \times m = r \times \overline{g\dot{t} + \frac{n}{m}\dot{v}} \times n$$

$$\text{Or } pmg\dot{t} - pm\dot{v} = rng\dot{t} + r\frac{n^2}{m}\dot{v}$$

$$\text{Or } pm^2g\dot{t} - pm^2\dot{v} = rmng\dot{t} + rn^2\dot{v}$$

$$\text{Or } \overline{pm^2 - rmn} \times g\dot{t} = \overline{pm^2 + rn^2} \times \dot{v}$$

That is, $pm^2 + rn^2 : pm^2 - rmn = g\dot{t} : \dot{v}$

That is, *the denominator of the fraction, expressing the velocity of the impelled point, is to the numerator as the velocity which a heavy body would acquire in the moment* $\dot{t}$, *by falling freely, is to the velocity which the impelled point acquires in that moment.* The same thing is true of the velocity of the working point.

This reasoning suffers no change from the more complicated nature of the general proposition. Here the impelling power is still p, but the matter to be accelerated by it at the working point is $a + y$, while its reaction, diminishing the impelling power, is only r. We have only to consider, in this case, the velocity with which $a + y$ would fall freely when impelled, not by $a + y$, but only by r. The result would be the same; $g\dot{t}$ would still be to $\dot{v}$ as the denominator of the same fraction to its numerator.

Thus have we discovered the momentary acceleration of our machine. It is evident, that if the pressures p and r, and the friction and inertia of the machine, and the external matter, continue the same, the acceleration will continue the same; the motion of rotation will be uniformly accelerated, and $pm^2 + \overline{a+y}n^2$ will be to $pm^2 - \overline{r+f}mn$ as the space s, through which a heavy body would fall in any given time t, is to the space through which the impelled point will really have moved in the same time. In like manner, the space through which the working point moves in the same time is $= \frac{pmn - \overline{r+f}n^2}{pm^2 + \overline{a+y}n^2}s$.

Thus are the motions of the working machine determined. We may illustrate it by a very simple example. Suppose a weight p of five pounds, descending from a pulley, and dragging up another weight r of three pounds on the other side. m and n are equal, and each may be called 1. The formula becomes $\frac{p-r}{p+r}s$, or $\frac{5-3}{5+3}s$, or $\frac{2}{8}, = \frac{1}{4}s$. Therefore, in a second, the weight p will descend $\frac{1}{4}$th of 16 feet, or 4 feet; and will acquire the velocity of 8 feet per second.

Having obtained a knowledge of the velocity of every point of the machine, we can easily ascertain its performance. This depends on a combination of the quantity of resistance that is overcome at the working point, and the velocity with which it is overcome. Thus, in raising water, it depends on the quantity (proportional to the weight) of water in the bucket or pump, and the velocity with which it is lifted up. This will be had by multiplying the third formula by r, or by $rg\dot{t}$, or by rs. Therefore we obtain this expression, 17 Performance of the machine.

$$\text{Work done} = \frac{pmrn - \overline{r+f}rn^2}{pm^2 + \overline{a+y}n^2}g\dot{t}. \text{ (IV)}$$

Such is the general expression of the momentary performance of the machine, including every circumstance which can affect it. But a variation of those circumstances produces great changes in the results. These must be distinctly noticed.

Cor. 1. If $pmrn$ be equal to $\overline{r+f}rn^2$, there will be no work done, because the numerator of the fraction is annihilated. There is then no unbalanced force, and the

the natural power is only able to balance the pressure propagated from the working point to the impelled point.

2. In like manner, if $n = o$, no work is done altho' the machine turns round. The working point has no motion. For the same reason, if m be infinitely great, although there is a great prevalence of impelling momentum, there will not be any sensible performance during a finite time. For the velocity which p can impress is a finite quantity, and the impelled point cannot move faster than x would be moved by it if detached from the machine. Now when the infinitely remote impelled point is moved through any finite space, the motion of the working point must be infinitely less, or nothing, and no work will be done.

Remark. We see that there are two values of n, viz. o, and $m \times \frac{p}{r}$, which give no performance. But in all other proportions of m and n some work is done. Therefore, as we gradually vary the proportion of m to n, we obtain a series of values expressing the performance, which must gradually increase from nothing, and then decrease to nothing. There must therefore be some proportion of m to n, depending on the proportion of p to $\overline{r+f}$, and of n to $\overline{a+y}$, which will give the greatest possible value of the performance. And, on the other hand, if the proportion of m to n be already determined by the construction of the machine already erected, there must be some proportion of p to $\overline{r+f}$, and of n to $\overline{a+y}$, by which the greatest performance of the machine may be ensured. It is evident, that the determination of these two proportions is of the utmost importance to the improvement of machines. The well informed reader will pardon us for endeavouring to make this appear more forcibly to those who are less instructed, by means of some very simple examples of the first principle.

Suppose that we have a stream of water affording three tons per minute, and that we want to drain a pit which receives one ton per minute, and that this is to be done by a wheel and axle? We wish to know the best proportion of their diameters m and n. Let m be taken $= 6$; and suppose,

1. That $n = 5$.

Then $\frac{p m r n - r^2 n^2}{p m^2 + r n^2} = \frac{3.6.1.5 - 1.25}{3.36 + 1.36}, = \frac{65}{133}, = 0{,}4887$

2. Let n be $= 6$. The formula is $= 0{,}5$.

3. Let $n = 7$. The formula is $= 0{,}49045$. Hence we find, that the performance is greater when n is 6, than when it is either 5 or 7.

As an example of the second principle, suppose the machine a simple pulley, and let p be 10.

1. Let r be $= 3$. The formula is $\frac{10 \times 3 - 9}{10 + 3}, = \frac{21}{13}, = 1{,}6154$.

2. Let r be $= 4$. The formula is $= \frac{10 \times 4 - 16}{10 + 4}, = \frac{24}{14}, = 1{,}7143$.

3. Let r be $= 5$. The formula is $= \frac{10 \times 5 - 25}{10 + 5}, = \frac{25}{15}, = 1{,}6666$. Here it appears, that more work is done when r is 4 than when it is 5 or 3.

It must therefore be allowed to be one of the most important problems in practical mechanics to determine that construction by which a given power shall overcome a given resistance with the greatest advantage, and the proportion of work which should be given to a machine already constructed so as to gain a similar end. 18

1. The general determination of the first question has but little difficulty. We must consider n as the variable magnitude in the formula $\frac{p m r n - \overline{r+f}\, r n^2}{p m^2 + \overline{a+y}\, n^2}$, which expresses the work done; and find its value when the formula is a maximum. Taking this method, we shall find that the formula IV. is a maximum when n is

Proportion of the machine which gives the greatest work.

$$= m \frac{\sqrt{x^2 (r+f)^2 + p^2 x (a+y)} - x(r+f)}{p(a+y)}.$$

This expression of the performance, in its best state, appears pretty complex; but it becomes much more simple in all the particular applications of it, as the circumstances of the case occur in practice.

We have obtained a value of n expressed in parts of m. If we substitute this for n in the third formula, we obtain the greatest velocity with which the resistance r, connected with the inertia y, can be overcome by the power p, connected with the inertia x, by the intervention of a machine, whose momentum of inertia and friction are $a n^2$ and $f n$. This is $= \frac{r+f}{2a+y} \times \left(\sqrt{\frac{p^2\, \overline{a+y}}{\overline{r+f}^2\, x} + 1} - 1\right) g\, i$. This expresses the velocity of the working point in feet per second, and therefore the actual performance of the machine.

But the proper proportion of m to n, ascertained by this process, varies exceedingly, according to the nature both of the impelling power, and of the work to be performed by the machine.

1. It frequently happens that the work exerts no contrary strain on the machine, and consists merely in impelling a body which resists only by its inertia. This is the case in urging round a millstone or a heavy fly; in urging a body along a horizontal plane, &c. In this case r does not enter into the formula, which now becomes $m \times \frac{\sqrt{x^2 f^2 + p^2 x (a+y)} - x f}{p(a+y)}$. If the friction be insignificant we may take $n = m \sqrt{\frac{p^2 x (a+y)}{p^2 (a+y)^2}} = m \sqrt{\frac{x}{a+y}}$. The velocity of the working point is nearly $= \frac{p}{2\sqrt{x\, \overline{a+y}}}$. In this case, it will be found that the velocity acquired at the end of a given time will be nearly in the proportion of the power applied to the machine.

2. On the other hand, and more frequently, the inertia of the external matter which must be moved in performing the work need not be regarded. Thus, in the grinding of grain, sawing of timber, boring of cylinders, &c. the quantity of motion communicated to the flour, to the saw dust, &c. is too insignificant to be taken into the account. In this case, y vanishes from the formula, which becomes extremely simple when the friction and inertia of the machine are inconsiderable. We shall

ſhall not be far from the truth if we make m to n as $2r$ to p, or $n = m \times \frac{p}{2r+f}$. In this caſe, the velocity of the working point is $\frac{p^2 x}{4x(r+f) + \frac{a p^2}{4(r+f)}}$.

But it is rare that machines of this kind have a ſmall inertia. They are generally very ponderous and powerful; and the force which is neceſſary for generating even a very moderate motion in the unloaded machine (that is, unloaded with any work), bears a great proportion to the force neceſſary for overcoming the reſiſtance oppoſed by the work. The formula muſt therefore be uſed in all the terms, becauſe a is joined with y. It would have been ſimpler in this particular, had a been joined with x in the expreſſion of the angular velocity.

3. In ſome caſes we need not attend to the inertia of the power, as in the ſteam engine. In this caſe, if taken ſtrictly, n appears to have no value, becauſe x is a factor of every term of the numerator. But the formula gives this general indication, that the more inſignificant the inertia of the moving power is ſuppoſed, the larger ſhould m be in proportion to n; provided always, that the impelling power is not, by its nature, greatly diminiſhed, by giving ſo great a velocity to the impelled point. This circumſtance will be particularly conſidered afterwards.

4. If the inertia of the power and the reſiſtance be proportional to their preſſures, as when the impelling power is water lying in the buckets of an overſhot wheel, and the work is the raiſing of water, minerals, or other heavy body, acting *only* by its weight; then p and r may be ſubſtituted for x and y, and the formula expreſſing the value of n, when the performance is a maximum, becomes

$$n = m \frac{\sqrt{p^2 \times \overline{r+f}^2 + p^2 \times \overline{a+r}} - p \times \overline{r+f}}{p \times \overline{a+r}}.$$

If, in this caſe, the inertia and friction of the machine may be diſregarded, as may often be done in pulleys, we have

$$n = m\sqrt{\frac{p}{r}+1} - 1.$$

If we make m the unit of the radii, and r the unit of force, we have

$$n = \sqrt{p+1} - 1, \text{ in parts of } m = 1.$$

Or, making $p = 1$, we have $n = \sqrt{\frac{1}{r}+1} - 1$.

Theſe very ſimple expreſſions are of conſiderable uſe, even in caſes where the inertia of the machine is very conſiderable, provided that it have no reciprocating motions. A ſimple wheel and axle, or a train of good wheelwork, have very moderate friction. The general reſults, therefore, which even very unlettered readers can deduce from theſe ſimple formulæ, will give notions that are uſeful in the caſes which they cannot ſo thoroughly comprehend. Some ſervice of this kind may be derived from the following little table of the beſt proportions of m to n, correſponding to the proportions of the power furniſhed to the engineer, and the reſiſtance which muſt be overcome by it. The quantity r is always $= 10$, and $m = 1$.

p	n	p	n
1	0,0488	10	0,4142
2	0,0954	20	0,7321
3	0,1402	30	1,
4	0,1832	40	1,2362
5	0,2246	50	1,4495
6	0,2649	60	1,6457
7	0,3038	70	1,8284
8	0,3416	80	2,
9	0,3784	90	2,1623
10	0,4142	100	2,3166

This muſt ſuffice for a very general view of the firſt problem.

II. The next queſtion is not leſs momentous, namely, to determine for a machine of a given conſtruction that proportion of the reſiſtance at the working point to the impelling power which will enſure the greateſt performance of the machine; that is, the proportion of m to n being given, to find the beſt proportion of p to r. 13 Beſt proportion of the power and work.

This is a much more complicated problem than the other; for here we have to attend to the variations both of the preſſures p and r, and alſo of the external matters x and y, which are generally connected with them. It will not be ſufficient therefore to treat the queſtion by the uſual fluxionary proceſs for determining the maximum, in which r is conſidered as the only varying quantity. We muſt, in this curſory diſcuſſion, reſt ſatisfied with a comprehenſion of the circumſtances which moſt generally prevail in practice.

It muſt either happen, that when r changes, there is no change (that is, of moment) in the maſs of external matter which muſt be moved in performing the work, or that there is alſo a change in this circumſtance. If no change happens, the denominator of the fourth formula, expreſſing the performance, remains the ſame; and then the formula attains a maximum when the numerator $p r m n - \overline{r+f}\, r n^2$ is a maximum. Alſo, we may include f without complicating the proceſs, by the conſideration, that f is always in nearly the ſame ratio to r; and therefore $r+f$ may be conſidered as a certain multiple of r, ſuch as $b r$. We may therefore omit f in the fluxionary equations for obtaining the maximum, and then, in computing the performance, divide the whole by b. Thus if the whole friction be $\frac{1}{20}$th of the reſiſting preſſure r, we have $r + f = \frac{21}{20}$ of r, and $b = \frac{21}{20}$. Having aſcertained the beſt value for r, we put this in its place in the fourth formula, and take $\frac{20}{21}$ of this for the performance. This will never differ much from the truth.

This proceſs gives us $p m n = 2 n^2 r$, and $r = \frac{p m n}{2 n^2}$, $= \frac{p m}{2 n}$; and if we farther ſimplify the proceſs, by making $p = 1$, and $m = 1$, we have $r = \frac{1}{2n}$; a moſt ſimple expreſſion, directing us to make the reſiſtance one half of what would balance the impelling power by the intervention of the machine.

This will evidently apply to many very important caſes,

cafes, namely, to all thofe in which the matter put in motion by the working point is but trifling.

But it alfo happens in many important cafes, that the change is at leaft equally confiderable in the inertia of the work. In this cafe it is very difficult to obtain a general folution. But we can hardly imagine fuch a change, without fuppofing that the inertia of the work varies in the fame proportion as the preffure excited by it at the working point of the machine; for fince r continues the fame in kind, it can rarely change but by a proportional change of the matter with which it is connected. Yet fome very important cafes occur where this does not happen. Such is a machine which forces water along a long main pipe. The refiftance to motion and the quantity of water do not follow nearly the fame ratio. But in the cafes in which this ratio is obferved, we may reprefent y by any multiple br of r, which the cafe in hand gives us; b being a number, integer, or fractional. In the farther treatment of this cafe, we think it more convenient to free r from all other combinations; and inftead of fuppofing the force f (which we made equivalent with the friction of the machine) to be applied at the working point, we may apply it at the impelled point, making the effective power $q = p - f$. For the fame reafons, inftead of making the momentum of the machine's inertia $= an^2$, we may make it am^2, and make $a + n = z$. Now, fuppofing q, or $p - f$, $= 1$, and alfo $m = 1$, our formula expreffing the performance becomes $\frac{rn - r^2n^2}{z + brn^2}$. This is a maximum when $r = \frac{\sqrt{z^2 + zbn} - z}{bn^2}$.

Cor. 1. If the inertia of the work is always equal to its preffure, as when the work confifts wholly in raifing a weight, fuch as drawing water, &c. then $b = 1$, and the formula for the maximum performance becomes $r = \frac{\sqrt{zn + z^2} - z}{n^2}$.

2. If the inertia of the impelling power is alfo the fame with its preffure, and if we may neglect the inertia and friction of the machine, the formula becomes $r = \frac{\sqrt{n + 1} - 1}{n^2}$.

Example. Let the machine be a common pulley, fo that the radii m and n are equal, and therefore $n = 1$. Then, $r = \frac{\sqrt{1 + 1} - 1}{1}, = \sqrt{2} - 1, = 0{,}4142$, &c. more than $\frac{4}{10}$ths of what would balance it.

Here follows a feries of the beft values of r, correfponding to different values of n. m and p are each $= 1$. The numbers in the laft column have the fame proportion to 1 which r has to the refiftance which will balance p.

$n = \frac{1}{4}$	$r = 1{,}8885$	0,4724 to 1
$\frac{1}{3}$	1,3928	0,4639
$\frac{1}{2}$	0,8986	0,4493
1	0,4142	0,4142
2	0,1830	0,3660
3	0,1111	0,3333
4	0,0772	0,3088

From what has now been eftablifhed, we fee with fufficient evidence the importance of the higher mathematics to the fcience of mechanics. If the velocities of the impelled and working points of an engine are not properly adjufted to the preffures, the inertia, and the friction of the machine, we do not derive all the advantages which we might from our fituation. Hence alfo we learn the falfity of the maxim which has been received as well founded, that the augmentation of intenfity of any force, by applying it to the long arm of a lever, is always fully compenfated by a lofs of time; or, as it is ufually expreffed, "what we gain by a machine in force we lofe in time." If the proportion of m to n is well chofen, we fhall find that the work done, when it refifts by its inertia only, increafes nearly in the proportion of the power employed; whereas when the inertia of the work is but a fmall part of the refiftance, it increafes nearly in the duplicate ratio of the power employed.

General but erroneous maxim.

It was remarked, in the fetting out in the prefent problem, that the formulæ do not immediately exprefs the velocity of any point of the machine, but its momentary acceleration. But this is enough for our purpofe; becaufe, when the momentary acceleration is a maximum, the velocity acquired, and the fpace defcribed, in any given time, is alfo a maximum. We alfo fhewed how the real velocities, and the fpaces defcribed, may be afcertained in known meafures. We may fay in general, that if g reprefent the preffure of gravity on any mafs of matter w, then $\frac{g}{w}$ is to $\frac{pmn - \overline{r + f}\,n}{am^2 + x + yn^2}$ as 16 feet to the fpace defcribed in a fecond by the working point in a fecond, or as 32 feet per fecond is to the velocity acquired in that time.

A remark now remains to be made, which is of the greateft confequence, and gives an unexpected turn to the whole of the preceding doctrines. It appears, from all that has been faid, that the motion of a machine muft be uniformly accelerated, and that any point will defcribe fpaces proportional to the fquares of the times; for while the preffures, friction, and momentum of inertia remain the fame, the momentary acceleration muft alfo be invariable. But this feems contrary to all experience. Such machines as are properly conftructed, and work without jolts, are obferved to quicken their pace for a few feconds after ftarting; but all of them, in a very moderate time, acquire a motion that is fenfibly uniform. Is our theory erroneous, or what are the circumftances which remain to be confidered, in order to make it agree with obfervation? The fcience of machines is imperfect, till we have explained the caufes of this deviation from the theory of uniform acceleration.

Caufes why machines do not continually accelerate.

Thefe caufes are various.

1. In fome cafes, every increafe of velocity of the machine produces an increafe of friction in all its communicating parts. By thefe means, the accelerating force, which is $pm - \overline{r + f}\,n$, or $\overline{p - f}\,m - rn$, is diminifhed, and confequently the acceleration is diminifhed. But it feldom happens that friction takes away or employs the whole accelerating force. We are not yet well inftructed in the nature of friction. Moft of the kinds of friction which obtain in the communicating parts of machines, are fuch as do not fenfibly increafe by an increafe of velocity; fome of them really diminifh. Yet even the moft accurately conftructed machines, unloaded with work, attain a motion that is fenfibly uniform. If we take off the pallets from a pen-

Increafe of friction.

dulum

dulum clock, and allow it to run down amain, it accelerates for a while, but in a very moderate time it acquires an uniform motion. So does a common kitchen jack. Theſe two machines ſeem to bid the faireſt of any for an uniformly accelerated motion; for their impelling power acts with the utmoſt uniformity. There is ſomething yet unexplained in the nature of friction, which takes away ſome of this acceleration.

Reſiſ But the chief cauſe of its ceſſation in theſe two inſtances, and others *of very rapid motion*, is the reſiſtance of the air. This ariſes from the motion which is communicated to the air diſplaced by the ſwift moving parts of the machine. At firſt it is very ſmall; but it increaſes nearly in the duplicate ratio of the velocity (ſee Re-SISTANCE *of Fluids*, Encycl.) Thus r increaſes continually; and, in a certain ſtate of motion, $\overline{r+fn}$ becomes equal to $p\,m$. Whenever this happens, the accelerating power is at an end. The acceleration alſo ceaſes; and the machine is in a ſtate of dynamical equilibrium; not at reſt, but moving uniformly, and performing work.

Incre of reſiſ very imperfect known Still, however, this is not one of the general cauſes of the uniform motion attained by working engines. Rarely is the motion of their parts ſo rapid, as to occaſion any great reſiſtance from the air. But in the moſt frequent employments of machines, every increaſe of velocity is accompanied by an increaſe of reſiſtance from the work performed. This occurs at once to the imagination; and few perſons think of inquiring farther for a reaſon. But there is perhaps no part of mechanics that is more imperfectly underſtood, even in our preſent improved ſtate of mechanical ſcience. In many kinds of work, it is very difficult to ſtate what increaſe of labour is required in order to perform the work with twice or thrice the ſpeed. In grinding corn, for inſtance, we are almoſt entirely ignorant of this matter. It is very certain, that twice the force is not neceſſary for making the mill grind twice as faſt, nor even for making it grind twice as much grain equally well. It is not eaſy to bring this operation under mathematical treatment; but we have conſidered it with ſome attention, and we imagine that a very great improvement may ſtill be made in the conſtruction of griſt mills, founded on the law of variation of the reſiſtance to the operation of grinding, and a ſcientific adjuſtment of m to n, in conſequence of our knowledge of this law. We may make a ſimilar obſervation on many other kinds of work performed by machines. In none of thoſe works where the inertia of the work is inconſiderable, are we well acquainted with the real mechanical proceſs in performing it. This is the caſe in ſawing mills, boring mills, rolling mills, ſlitting mills, and many others, where the work conſiſts in overcoming the ſtrong coheſion of a ſmall quantity of matter. In ſawing timber (which is the moſt eaſily underſtood of all theſe operations), if the ſaw move with a double velocity, it is very difficult to ſay how much the actual reſiſting preſſure on the teeth of the ſaw is increaſed. Twice the number of fibres are neceſſarily torn aſunder during the ſame time, becauſe the ſame number are torn by one deſcent of the ſaw, and it makes that ſtroke in half the time. But it is very uncertain whether the reſiſtance is double on this account; becauſe if each fibre be ſuppoſed to have the ſame tenacity in both caſes, it reſiſts with this tenacity only for half the time. The parts of bodies reſiſt a ſimilar change of condition in different manners; and there is another difference in their reſiſtance of different changes—the reſiſtance of red hot iron under the roller may vary at a very different rate from that of its reſiſtance to the cutting tool. The reſiſtance of the ſpindles of a cotton mill, ariſing partly from friction, partly from the inertia of the heaped bobins, and partly from the reſiſtance of the air, is ſtill more complicated, and it may be difficult to learn its law. The only caſe in which we can judge with ſome preciſion is, when the inertia of matter, or a conſtant preſſure like that of gravity, conſtitutes the chief reſiſtance. Thus in a mill employed to raiſe water by a chain of buckets, the reſiſtance proceeds from the inertia only of the water. The buckets are moving with a certain velocity, and the loweſt of them takes hold of a quantity of water lying at reſt in the pit, and drags it into motion with its acquired velocity. The force required for generating this motion on the quieſcent water muſt be double or triple, when the velocity that muſt be given to it is ſo. This abſorbs the overplus of the impelling power, by which that power exceeds what is neceſſary for balancing the weight of the water contained in all the aſcending buckets. This is a certain determinate quantity which does not change; for in the ſame inſtant that a new bucket of water is forced into motion below, and its weight added to that of the aſcending buckets, an equal bucket is emptied of its water at top. The aſcending buckets require only to be balanced, and they then *continue* to aſcend, with any velocity already acquired. While the machine moves ſlow, the motion impreſſed on the new bucket of water is not ſufficient to abſorb all the overplus of impelling power. The quantity not abſorbed accelerates the machine, and the next bucket muſt produce more motion in the water which it takes up. This conſumes more of the overplus. This goes on till no overplus of power is left, and the machine accelerates no more. The complete performance of the machine now is, that "a certain quantity of water, formerly at reſt, is now moving with a certain velocity." Our engineers conſider it differently; "as a certain *weight* of water lifted up." But while the machine is thus moving uniformly, it is really not doing ſo much as before; that is, it is not exerting ſuch great preſſures as before the motion was rendered uniform: for at that time there was a preſſure at the working point equal to the weight of all the water in the aſcending buckets; and alſo an overplus of preſſure, by which the whole was accelerated. In the ſtate of uniform motion, the preſſure is no more than juſt balances the weight of the aſcending chain. We ſhall learn by and bye how the preſſures have been diminiſhing, although the mill has been accelerating; a thing that ſeems a paradox.

In this inſtance, then, we ſee clearly, why a machine muſt attain a uniform motion. A pumping machine gives us the ſame opportunity, but in a manner ſo different as to require explanation. The piſton may be ſuppoſed at the very ſurface of the pit water, and the impelling power may be leſs than will ſupport a column in the pipe as high as can be raiſed by the preſſure of the atmoſphere. Suppoſe the impelling power to be the water lying in the buckets of an overſhot wheel.

Let

Let this water be laid into the buckets by a very small stream. It will fill the buckets very slowly; and as this gives them a preponderance, the mill loses its balance, the wheel begins to move, and the piston to rise, and the water to follow it. The water may be delivered on the wheel drop by drop; the piston will rise by insensible degrees, always standing still again as soon as the atmospheric pressure on it just balances the water on the wheel. The water in the rising pipe is always a balance to the pressure of the atmosphere on the cistern; therefore the pressure of the atmosphere on the piston (which is the *r* in our formula) is equal to the weight of this water. Our pump-makers therefore (calling themselves engineers) say, that the weight of water in the pipe balances the water on the wheel. It does not balance it, nor is it raised by the wheel, but by the atmosphere; but it serves us at present for a measure of the power of the wheel. At last, all the buckets of the wheel are full, and the water is (for example) 25 feet high in the pipe. Now let the stream of water run its full quantity. It will only run over from bucket to bucket, and run off at the bottom of the wheel; but the mill will not move, and no work will be performed. (N. B. We are here excluding all impulse or stroke on the buckets, and supposing the water to act only by its weight.) But now let all be emptied again, and let the water be delivered on the wheel in its full quantity at the first. The wheel will immediately acquire a preponderancy, which will *greatly* exceed the first small pressure of the atmosphere on the piston. It will therefore accelerate the piston, overcoming the pressure of the air with great velocity. The piston rises fast; the water follows it, by the pressure of the atmosphere; and when it attains the former utmost height, it attains it with a considerable velocity. If allowed to run off there, it will *continue* to run off with that velocity; because there is the same quantity of water pressing round the wheel as before, and therefore enough to balance the pressure of the atmosphere on the piston. The pressure of the same atmosphere on the water in the cistern, raised the water in the pipe with this velocity; therefore it will continue to do so, and the mill will deliver water by the pump with this velocity, although there is no more pressure acting on it than before, when the water ran to waste, doing no work whatever.

This mode of action is extremely different from the former example. The mill is not acting against the inertia *y* of the water to be moved, but against the pressure *r* of the atmosphere on the piston. The pressure of the same atmosphere on the cistern is employed against the inertia of the water in the pipe; and the use of the mill is to *give occasion*, by raising the piston, to the exertion of this atmospherical pressure, which is the real raiser of the water. The maxim of construction, and the proper adjustment of *m* to *n* in this case, are different from the former; and we should run the risk of making an imperfect engine were we to confound them.

We must mention another case of a pumping mill, seemingly the same with this, but essentially different. Suppose the pipe of this pump to reach 30 feet below the surface of the pit water, and that the piston is at the very bottom of it. Suppose also, that the wheel buckets, when filled with water, only enable it to *support* 25 feet of water in the rising pipe. Let the water be delivered into the wheel drop by drop. The wheel will gradually preponderate; the piston will gradually rise, lifting the water above it, sustaining a pressure of water which gradually increases. At last, the water in the pump is 25 feet higher than that in the cistern; the wheel is full and running to waste; but no work is performed. Let all be emptied, and now let the water come to the wheel in its full stream, but without impulse. The piston will lift the water briskly, bring it to 25 feet high with a considerable velocity, and the mill will now raise it with this velocity. In this example, the mill is the immediate agent in raising the water; but, in this case also, its ultimate office is not overcoming inertia, but overcoming pressure. It was the overplus of power only that was employed in overcoming inertia, while accelerating the water in the rising pipe, in order to give it the necessary velocity for a continued discharge.

21. These and similar examples shew the great difference between the statical and dynamical equilibrium of machines, and the necessity of a scientific attention by all who wish to improve practical mechanics. Without this, and even a pretty refined attention, we cannot see the connection between a copious supply of water to the bucket wheel and a plentiful discharge by the pump. We believe, that the greatest part of those employed in erecting machines conceive it as owing to the greater weight of water impelling the wheel with greater force; but we see that there is no difference in the pressures on the mill at rest, and the mill doing its work steadily and uniformly, with any velocity, however great. Without keeping the notions of that part of the impelling power which supports distinct from that of the part which accelerates, we shall never have a clear conception of the operation of machines, or of mechanical power in general. We cannot derive all the advantages of our natural powers, without knowing how our machine employs the pressure excited by it at the working point; that is, without perceiving in what cases it is opposed to inertia, and in what to the mechanical properties of tangible matter. This only can inform us at what rate the resistance varies by a change of velocity; and when it happens that this augmentation, necessarily accompanied by an augmentation of all the frictions, and the resistance of the air, is in equilibrio with the whole of the impelling power, and all acceleration is at an end.

22 The chief cause is a real diminution of power.

Lastly, another chief cause of the finally uniform motion of machines is, that, in most cases, an increase of velocity produces a real diminution of impelling power. We hardly know any exception to this besides the employment of *one* descending weight as a power or first mover. Most of the powers which we employ reside in bodies external to the machine; and these bodies must be put in motion, and continued in that motion, in order to continue their pressure on the impelled point. Frequently a great part of the power is employed in giving this necessary motion to the external matter, and the remainder only is employed in pressing forward the machine. We mentioned a remarkable instance of this in the operation of thrashing. Now, the power thus employed must increase in proportion to the motion required; that is, in proportion to the velocity of the impelled

pelled point; what remains, urging forward the machine, is therefore diminished. The acceleration is therefore diminished, and may cease At *last* the actual pressure is so much diminished, that it is no more than what is necessary for overcoming the increased resistance of the work, the increased friction. The machine therefore accelerates no more, but moves uniformly.

This cause by gene- This cause of the diminution of power by an increase of velocity, obtains in all cases where the strength of animals, of springs, the force of fired gunpowder, &c. is exerted. In some cases, the visible effect is not very considerable; as in the employment of a strong spring, the force of gunpowder, and a few others. In the action of animals, this defalcation of power is very great when the velocity is considerable. Nay, even in the action of gravity, although it acts as strongly on a body in rapid motion as on one at rest, yet when gravity is not the immediate agent, but acts by the intervention of a body in which it resides, the necessity of previously moving this body frequently diminishes the acceleration which it would otherwise produce Thus, in an overshot wheel, if the water be delivered into the bucket with a velocity (estimated in the direction of the part of the wheel into which it is delivered) less than that of the rim of the wheel, it must retard the motion; for it must be immediately dragged into that motion; that is, part of the accelerating overplus, already acting on the wheel, must be employed in accelerating this new bucket of water, and this must lessen the general acceleration of the machine Hence we learn, that the water must be delivered on the wheel with a velocity that is at least not less than that of the wheel's motion.

ᵘnated impulse The case in which we see this diminution of power on machines most distinctly is, when water or wind, acting by impulse alone, is our moving power. Since the mutual impulses of bodies depend entirely on their relative motions (see Impulsion, *Suppl.*), it follows, that when the velocity of the impelled point is augmented, the impulsion, or effective pressure, must be diminished. Nay, this velocity may be so increased, that there shall be no relative motion, and therefore no impulsion. If the floats of an undershot wheel be moving with the velocity of the stream, they remain conjoined in their progress, but without any mutual action. Therefore, when an undershot wheel is set into a running water, the first impulsions are strong, and accelerate the wheel. This diminishes the next impulsion and acceleration: but the wheel is still impelled and accelerated; less and less in every succeeding moment, as it moves faster; by and bye, the acceleration becomes insensible, and the wheel appears to attain a motion which is perfectly uniform. This requires a very long time, or rather it is never attained, and we only cannot discern the very small additions which are still made to the velocity. All this happens generally after a very moderate time, by reason of various other obstructions.

Or by the force of animals. Animal action is subject to the same variation. We know, that there is a certain rate at which a horse can run, exhausting or employing his whole strength. If he be made to drag any the smallest load after him, he must employ part of his force on it, and his speed will be checked. The more he is loaded with a draught, the slower he will run, still employing all his strength. The draught may be increased till he is reduced to a trot, to a walk, nay, till he is unable to draw it. Now, just inverting this process, we see, that there is a certain strain which will sufficiently tire the horse without stirring from the spot, but which he could continue to exert for hours. This is greater than the load that he can just crawl along with, employing his strength as much as would be prudent to continue from day to day. And, in like manner, every lesser draught has a corresponding rate, at which the horse, employing his whole working strength, can continue to draw at during the working hours of a day. At setting out, he pulls harder, and accelerates it. Following his pull, he walks faster, and therefore pulls less (because we are still supposing him to employ his whole working strength). At last he attains that speed which occupies his whole strength in merely continuing the pull. Other animals act in a similar manner; and it becomes a general rule, that the pressure actually exerted on the impelled point of a machine diminishes as its velocity increases.

23 We must distinguish between the power expended and the power employed. From the concurrence of so many facts, we perceive that we must be careful to distinguish between the quantity of power expended, and the quantity that is usefully employed, which must be measured solely by the pressure exerted on the machine. When a weight of five pounds is employed to drag up a weight of three pounds by means of a thread over a pulley, it descends, with a motion uniformly accelerated, four feet in the first second. Mr Smeaton would call this an expenditure of a mechanical power 20. The weight three pounds is raised four feet. Mr Smeaton would call this a mechanical effect 12. Therefore the effect produced is not adequate to the power expended. But the fact is, that the pressure, strain, or mechanical power really exerted in this experiment, is neither five nor three pounds; the five pound weight would have fallen 16 feet, but it falls only 4. A force has therefore acted on it sufficient to make it describe 12 feet in a second, with a uniformly accelerated motion; for it has counteracted so much of its weight. The thread was strained with a force equal to $3\frac{3}{4}$ pounds, or $\frac{3}{4}$ths of 5 pounds. In like manner, the three pound weight would have fallen 16 feet; but it was raised 4 feet. Here was a change precisely equal to the other. A force of $3\frac{3}{4}$ pounds, acting on a mass whose matter is only 3, will, in a second, cause it to describe 20 feet with a uniformly accelerated motion. Now, 5×12, and 3×20, give the same product 60. And thus we see, that the quantity of motion extinguished or produced, and not the product of the weight and height, is the true unequivocal measure of mechanical power really expended, or the mechanical effect really produced; and that these two are always equal and opposite. At the same time, Mr Smeaton's theorem merits the attention of engineers; because it generally measures the opportunities that we have for procuring the exertion of power. In some sense Mr Smeaton may say, that the quantity of water multiplied by the height from which it descends in working our machines, is the measure of the power expended; because we must raise this quantity to the dam again, in order to have the same use of it. It is expended, but not employed; for the water, at leaving the wheel, is still able to do something.

It requires but little consideration to be sensible, that, 24 the

the preceding account of the cessation of accelerated motion in our principal machines, must introduce different maxims of construction from those which were expressly adapted to this acceleration; or rather, which proceeded on the erroneous supposition of the constancy of the impelling power and the resistance. The examination of this point has brought into view the fundamental principle of working machines, namely, the perfect equilibrium which takes place between the impelling power and the simultaneous resistance. It may be expressed thus:

First principle of working machines.

The force required for preserving a machine in uniform motion, with any velocity whatever, is that which is necessary for balancing the resistance then actually exerted on the working point of the machine. We saw this distinctly in the instance of the two weights acting against each other by the intervention of a thread over a fixed pulley. It is equally true of every case of acting machinery: for if the force at the impelled point be greater than what balances the resistance acting at the same point, it must accelerate that point, and therefore accelerate the whole machine; and if the impelling force be less than this, the machine must immediately retard in its motion. When the machine has once acquired this degree of motion, every part of it will continue in its present state of motion, if only the two external forces are in equilibrio, but not otherwise. But when the pressure of the external power on the impelled point balances the resistance opposed by that point, it is, in fact, maintaining the equilibrium with the external power acting at the working point; for this is the only way that external forces can be set in opposition to each other by the intervention of a body. The external forces are not in immediate equilibrio with each other, but each is in equilibrio with the force exerted by the point on which it acts. This force exerted by the point is a modification of the connecting forces of the body, all of which are brought into action by means of the actions of the external forces, and each is accompanied by a force precisely equal and opposite to it. Now, the principles of statics teach us the proportions of the external pressures which are thus set in equilibrium by the intervention of a body; and therefore teach us what proportion of power and resistance will keep a machine of a given construction in a state of uniform motion.

This proposition appears paradoxical, and contrary to common observation; for we find, that, in order to make a mill go faster, we must either diminish the resistance, or we must employ more men, or more water, or water moving with greater velocity, &c. But this arises from some of the causes already mentioned. Either the resistance of the work is greater when the machine is made to move faster, or the impulsion of the power is diminished, or both these changes obtain. Friction and resistance of air also come in for their share, &c. The actual pressure of any given quantity of the external power is diminished, and therefore more of it must be employed. When a weight is *uniformly* raised by a machine, the pressure exerted on it by the working point is precisely equal to its weight, whatever be the velocity with which it rises. But, even in this simplest case, more natural power must be expended in order to raise it faster; because either more natural power must be employed to accelerate the external matter which is to press forward the impelled point, or the relative motion of the pressing matter will be diminished.

It is well known, that, in the employment of the mechanic powers, whether in their state of greatest simplicity, or any how combined in a complicated machine, if the machine be put in motion, the velocities of the extreme points (which we have called the *impelled* and *working* points) are inversely proportional to the forces which are in equilibrio when applied to these points in the direction of their motion. This is an inductive proposition, and has been used as the foundation of systems of mechanics. It is unnecessary to take up time in proving what is so familiarly known; consequently, the products of the pressures at those points by the velocities of the motions are equal; that is, the product of the pressure actually exerted at the impelled point of a machine working uniformly, multiplied by the velocity of that point, is equal to the product of the resistance actually exerted at the working point, multiplied by the velocity of that point, that is, by the velocity with which the resistance is overcome,

$$p\,m = r\,n.$$

Now, the product of the resistance, by the velocity with which it is overcome, is evidently the measure of the performance of the machine, or the work done. The product of the actual pressure on the impelled point, by the velocity of that point, may be called the MOMENTUM OF IMPULSE.

23 Second principle. Momentum of impulse and the performance of the machine are equal.

Hence we deduce this proposition:

In all working machines which have acquired a uniform motion, the performance of the machine is equal to the momentum of impulse. (A)

N 2 This

(A) The truth of this proposition has been long perceived in every particular instance that happened to engage the attention; but we do not recollect any mechanician before Mr Euler considering it as a general truth, expressing in a few words a mechanical law. This celebrated mathematician undertook, about the year 1735 or 1736, a general and systematic view of machines, in order to found a complete theory immediately conducive to the improvement of practical mechanics. In 1743 he published the first propositions of this useful theory in the 10th volume of the *Comment. Petropolitani*, containing the excellent dynamical theorems of which we have given the substance. In the 3d volume of the *Comment. Novi Petropol.* he prosecuted the subject a little farther; and in the 8th volume, he entered on what we are now engaged in, and formally announces this fundamental proposition, calling these two products the *momentum of impulse*, and the *momentum of effect*. It is much to be regretted, that this consummate mathematician did not continue these useful labours; his ardent mind being carried away by more abstruse speculations in all the most refined departments of mathematics and philosophy. No man in Europe could have prosecuted the subject with more judgment and success.—See also *Mem. Acad. Berlin*, 1747 and 1752.

This is a proposition of the utmost importance in the science of machines, and leads to the fundamental maxim of their construction. Since the performance of a machine is equal to the momentum of impulse, it increases and diminishes along with it, and is a maximum when the momentum of impulse is a maximum; therefore the fundamental maxim in the construction of a machine is to fashion it in such a manner, that the momentum of impulse shall be a maximum, or that the product of the pressure actually exerted on the impelled point of the machine by the velocity with which it moves may be as great as possible. Then are we certain that the product of the resistance, by the velocity of the working point, is as great as possible, provided that we take care that none of the impulse be needlessly wasted by the way by injudicious communications of motion, by friction, by unbalanced loads, and by reciprocal motions, which irrecoverably waste the impelling power. This maxim holds good, whether the resistance remains constantly the same, or varies by any law whatever.

26 Important considerations for practice.

But much remains to be done for the improvement of mechanical science before we can avail ourselves of this maxim, and apply it with success. The chief thing, and to this we should give the most unremitting attention, is, to learn the changes which obtain in the actual pressure exerted by those natural powers which we can command; the changes of actual pressure produced by a change of the velocity of the impelled point of the machine. These depend on the specific natures of those powers, and are different in almost every different case. Nothing will more contribute to the improvement of practical mechanics than a series of experiments, well contrived, and accurately made, for discovering those laws of variation, in the cases of those powers which are most frequently employed. Such experiments, however, would be costly, beyond the abilities of an individual; therefore, it were greatly to be wished that public aid were given to some persons of skill in the science to institute a regular train of experiments of this kind. An experimental machine might be constructed, to be wrought either by men or by cattle. This should be loaded with some kind of work which can be very accurately measured, and the load varied at pleasure. When loaded to a certain degree, the men or cattle should be made to work at the rate which they can continue from day to day. The number of turns made in an hour, multiplied by the load, will give the performance corresponding to the velocities; and thus will be discovered the most advantageous rate of motion. The same machine should also be fitted for grinding, for sawing, boring, &c. and similar experiments will discover the relation between the velocities with which these operations are performed, and the resistances which they exert. The laws of friction may be investigated by the same machine. It should also be fitted with a walking wheel, and the trial should be made of the slope and the velocity of walking which gives the greatest momentum of impulse. It is not unreasonable to expect great advantages from such a train of experiments.

27 A substitute for them.

Till this be done, we must content ourselves with establishing the above, in the most general terms, applicable to any case in which the law of the variation of force may hereafter be discovered.

There is a certain velocity of the impelled point of a machine which puts an end to the action of the moving power. Thus, if the floats of an undershot wheel be moving with the velocity of the stream, no impulse is made on them. If the arm of a gin or capstan be moving with that velocity with which a horse or a man can just move, so as to continue at that speed from day to day, employing all his working strength, but not fatiguing himself; in this state of motion, the animal can exert no pressure on the machine. This may be called the EXTINGUISHING VELOCITY, and we may express it by the symbol e. Let f be that degree of force or pressure which the animal can exert at a dead pull or thrust, as it is called. We do not mean the utmost strain of which the animal is capable, but that which it can continue unremittingly during the working hours of a day, fully employing, but not fatiguing itself. And let p be the pressure which it actually exerts on the impelled point of a machine, moving with the velocity m. Let $e-m$ be called the RELATIVE VELOCITY, and let it be expressed by v. And let it be supposed, that it has been discovered, by any means whatever, that the actual pressure varies in the proportion of v^q, or $\overline{e-m}^q$. This supposition gives us $e^q : v^q = f : p$, and $p = f \times \frac{v^q}{e^q}$. For the machine must be at rest, in order that the agent may be able to exert the force f on its impelled point. But when the machine is at rest, what we have named the relative velocity is e, the whole of the extinguishing velocity.

The momentum of impulse is $p\,m$, that is $\frac{v^q}{e^q} f\,m$, or $f \times \frac{v^q}{e^q} \times \overline{e-v}$ (because $m = e-v$). Therefore $f \times \frac{v^q}{e^q} \times \overline{e-v}$ must be made a maximum. But f and e^q are two quantities which suffer no change. Therefore the momentum of impulse will be a maximum when $v^q \times \overline{e-v}$ is a maximum. Now $v^q \times \overline{e-v} = v^q e - v^q v, = v^q e - v^{q+1}$. The fluxion of this is $q\,e\,v^{q-1}\dot{v} - \overline{q+1}\,v^q\dot{v}$. This being supposed $= 0$, we have the equation

$$q\,e\,v^{q-1} = \overline{q+1}\,v^q$$

$$\text{And } q\,e = \overline{q+1}\,v$$

$$\text{Therefore } v = \frac{q\,e}{q+1}$$

And m, which is $= e-v$, becomes $\frac{e}{q+1}$. Therefore we must order matters so, that the velocity of the impelled point of the machine may be $= \frac{e}{q+1}$. Now p is $= f\frac{v^q}{e^q}$, and therefore $= f \times \frac{q^q}{\overline{q+1}^q}$. And $p\,m$, $= f\frac{q^q}{\overline{q+1}^q}m, = f\frac{q^q}{\overline{q+1}^q} \times \frac{e}{q+1}, = f \times \frac{q^q e}{\overline{q+1}^{q+1}} =$ the momentum of impulse, and therefore $=$ the momentum of effect, or the performance of the machine, when in its best state.

Thus may the maxim of construction be said to be brought to a state of great simplicity, and of most easy recollection. A particular case of this maxim has been long known, having been pointed out by Mr Parent. Since the action of bodies depends on their relative velocity,

28 Example in undershot mills by Mr Parent.

locity, the impulse of fluids must be as the square of the relative velocity. From which Mr Parent deduced, that the most advantageous velocity of the floats of an undershot wheel is one third of that of the stream. This maxim is evidently included in our general proposition; for in this case, the index q of that function of the relative velocity v, which is proportional to the impulse, is $= 2$. Therefore we have the maximum when $v = \frac{2e}{2+1}, = \frac{2}{3}e$, and $m = \frac{1}{3}e$. e, the extinguishing velocity, is evidently the velocity of the stream. Our proposition also gives us the precise value of the performance. The impulse of the stream on the float at rest being supposed $= f$, its impulse on the float moving with the velocity $\frac{2}{3}e$ must be $= \frac{4}{9}f$. This is the measure of the actual pressure p. This being multiplied by m, or by $\frac{1}{3}e$, gives $\frac{4}{27}f$. Now f is considered as equal to the weight of a column of water, having the surface of the floatboard for its base, and the depth of the sluice under the surface of the reservoir (or, more accurately, the fall required for generating the velocity of the stream) for its height. Hence it has been concluded, that the utmost performance of an undershot wheel is to raise $\frac{4}{27}$ of the water which impels it, to the height from which it falls. But this is not found very agreeable to observation. Friction, and many imperfections of execution in the delivery of the water, the direction of its impulse, &c. may be expected to make a defalcation from this theoretical performance. But the actual performance, even of mills of acknowledged imperfection, considerably exceeds this, and sometimes is found nearly double of this quantity. The truth is, that the particular fact from which Mr Parent first deduced this maxim (namely, the performance of what is called *Parent's* or *Dr Barker's mill*), is, perhaps of all that could have been selected, the least calculated for being the foundation of a general rule, being of a nature so abstruse, that the first mathematicians of Europe are to this day doubtful whether they have a just conception of its principles. Mr Smeaton's experiments shew very distinctly, that the maximum of performance of an undershot wheel corresponds to a velocity considerably greater than one-third of the stream, and approaches nearly to one-half; and he assigns some reasons for this which seem well founded. But, independent of this, the performance of Mr Smeaton's model was much greater than what corresponds with the velocity by the above mentioned estimation of f. The theory of the impulsion of fluids is extremely imperfect; and Daniel Bernoulli shews, from very unquestionable principles, that the impulse of a narrow vein of fluid on an extended surface is double of what was generally supposed; and his conclusions are abundantly confirmed by the experiments adduced by him.

Not accurate.

29 It is by no means pretended, that the maxim of construction is reduced to the great simplicity enounced in the proposition now under consideration. We only supposed, that a case had been observed where the pressure exerted by some natural agent did follow the proportions of v^q. This being admitted, the proposition is strictly true. But we do not know any such case; yet is the proposition of considerable use: for we can affirm, on the authority of our own observations, that the action both of men and of draught horses does not deviate very far from the proportions of v^2. The observations were made on men and horses tracking a lighter along a canal, and working several days together, without having any knowledge of the purpose of the observations. The force exerted was first measured by the curvature and weight of the track rope, and afterwards by a spring steelyard. This was multiplied by the number of yards per hour, and the product considered as the momentum. We found the action of men to be very nearly as $\overline{e - m}^2$. The action of horses, loaded so as not to be able to trot, was nearly as $\overline{e - m}^{1,7}$.

...is subject... useful, even where it... not altogether exact.

The practitioner can easily avail himself of the maxim, although the function q should never be reduced to any algebraic form. He has only to institute a train of experiments on the natural agent, and select that velocity which gives the highest product when multiplied by its corresponding pressure.

When this selection has been made, we have two ways of giving our working machines the maximum of effect, having once ascertained the pressure f which our natural power exerts on the impelled point of the machine when it is not allowed to move. 30

Two methods of availing ourselves of this maxim.

1. When the resistance arising from the work, and from friction, is a given quantity; as when water is to be raised to a certain height by a piston of given dimensions.

Since the friction in all the communicating parts of the machine vary in the same proportion with the pressure, and since these vary in the same proportion with the resistance, the sum of the resistance and friction may be represented by $b\,r$, b being an abstract number. Let n be the undetermined velocity of the working point; or let $m : n$ be the proportion of velocities at the impelled and working points. Then, because the pressures at these points balance each other, in the case of uniform motion, they are inversely as the velocities at those points. Therefore we must make $b\,r : p = m : n$, and $n = \frac{p\,m}{b\,r}, = \frac{\frac{q^q}{\overline{q+1}^q} f m}{b\,r}, = m \frac{q^q f}{\overline{q+1}^q\, b\,r}$, or $m : n = \overline{q+1}^q \times b\,r : q^q f$.

2. On the other hand, when $m : n$ is already given, by the construction of the machine, but $b\,r$ is susceptible of variation, we must load the machine with more and more work, till we have reduced the velocity of its impelled point to $\frac{e}{q+1}$.

In either case, the performance is expressed by what expresses $p\,m$, that is, by $f e \times \frac{q^q}{\overline{q+1}^{q+1}}$. But the useful performance, which is really the work done, will be had by dividing the value now obtained by the number b, which expresses the sum of the resistance overcome by the working point and the friction of the machine.

What has been now delivered contains, we imagine, the chief principles of the theory of machines, and points out the way in which we must proceed in applying them to every case. The reader, we hope, sees clearly the imperfection of a considera-

Recapitulation.

tion

tion of machines which proceeds no farther than the statement of the proportions of the simultaneous pressures which are excited in all the parts of the machine by the application of the external forces, which we are accustomed to call the *power* and the *weight*. Unless we take also into consideration, the immediate effect of mechanical force applied to body, and combine this with all the pressures which statical principles have enabled us to ascertain, and by this combination be able to say what portion of unbalanced force there is acting at one and all of the pressing points of the machine, and what will be the motion of *every part* of it in consequence of this overplus, we have acquired no knowledge that can be of service to us. We have been contemplating, not a working machine, but a sort of balance. But, by reasoning about these unbalanced forces in the same simple manner as about the fall of heavy bodies, we were able to discover the momentary accelerations of every part, and the sensible motion which it would acquire in any assigned time, if all the circumstances remain the same. We found that the results, although deduced from unquestionable principles, were quite unlike the observed motions of most working machines. Proceeding still on the same principles, we considered this deviation as the indication, and the precise measure, of something which we had not yet attended to, but which the deviation brought into view, and enabled us to ascertain with accuracy. These are the changes which happen in the exertions of our actuating powers by the velocity with which we find it convenient to make them act. Thus we learn more of the nature of those powers; and we found it necessary to distinguish carefully between the apparent magnitude of our actuating power and its real exertion in doing our work. This consideration led us to a fundamental proposition concerning all working machines when they have attained an uniform motion; namely, that the power and resistance then really exerted on the machine precisely balance each other, and that the machine is precisely in the condition of a steelyard loaded with its balanced weights, and moved round its axis by some external force distinct from the power and the weight. We found that this force is the previous overplus of impelling power, before the machine had acquired the uniform motion; and on this occasion we learned to estimate the effect produced, by the momentum (depending on the form of the machine) of the quantity of motion produced in the whole assemblage of power, resistance, and machine.

31 Theory of machines still intricate, especially of such as reciprocate.

The theory of machines seemed to be now brought back to that simplicity of equilibrium which we had said was so imperfect a foundation for a theory; but in the availing ourselves of the maxim founded on this general proposition, we saw that the equilibrium is of a very different kind from a quiescent equilibrium. It necessarily involves in it the knowledge of the momentary accelerations and their momenta; without which we should not perceive that one state of motion is more advantageous than another, because all give us the same proportion of forces in equilibrio.

But this is not the only use of the previous knowledge of the momentary accelerations of machines; there are many cases where the machine works in this very state. Many machines accelerate throughout while performing their work ... their efficacy depend-ently on the final acceleration. Of this kind is the coining press, the great forge or tilt mill, and some other capital engines. The steam engine, and the common pump, are necessarily of this class, although their efficacy is not estimated by their final acceleration. A great number of engines have reciprocating motions in different subordinate parts. The theory of all such engines requires for its perfection an accurate knowledge of the momentary accelerations; and we must use the formulæ contained in the first part of this article.

32 Working and returning strokes.

Still, however, the application of this knowledge has many difficulties, which make a *good* theory of such machines a much more intricate and complicated matter than we have yet led the reader to suppose. In most of these engines, the whole motion may be divided into two parts. One may be called the WORKING STROKE, and the other in which the working points are brought back to a situation which fits them for acting again, may be called the RETURNING STROKE. This return must be effected either by means of some immediate application of the actuating power, or by some other force, which is counteracted during the working stroke, and must be considered as making part of the resistance. In the steam engine, it is generally done by a counterpoise on the outer end of the great working beam. This must be accounted a part of the resistance, for it must be raised again; and the proportions of the machine for attaining the maximum must be computed accordingly. The quantity of this counterpoise must be adjusted by other considerations. It must be such, that the descent of the pump rods in the pit may *just employ the whole time* that is necessary for filling the cylinder with steam. If they descend more briskly (which an unskilful engineer likes to see), this must be done by means of a greater counterpoise, and this employs more power to raise it again. Desaguliers describes a very excellent machine for raising water in a bucket, by a man's stepping into an opposite bucket, and descending by his preponderancy. When he comes to the bottom, he steps out, goes up a stair, and finds the bucket returned and ready to receive him again. This machine is extremely simple, and perhaps the best that can be contrived; and yet it is one of the most likely to be a very bad one. The bucket into which the man steps must be brought up to its place again by a preponderancy in the machine when unloaded. It may be returned sooner or later. It should arrive precisely at the same time with the man. If sooner, it is of no use, and wastes power in raising a counterpoise which is needlessly heavy; if later, time is lost: Therefore, the perfection of this very simple machine requires the judicious combination of two maximums, each of which varies in a ratio compounded of two other ratios. Suppose the man to employ a minute to go up stairs 50 feet, which is very nearly what he can do from day to day as his only work, and suppose him to weigh 150 pounds, and that he acts by means of a simple pulley—the maximum for a lever of equal arms would require him to raise about 60 pounds of water. But when all the other circumstances are calculated, it will be found that he must raise 138 pounds (neglecting the inertia of the machine). He should raise 547 pounds 10 feet in a minute; and this is nearly the most exact valuation of a man's work.

There is the same necessity of attending to a variety

of circumſtances in all machines which reciprocate in the whole or any conſiderable part of their motion. The force employed for bringing the machine into another working poſition, muſt be regulated by the time neceſſary for obtaining a new ſupply of power; and then the proportion of x to n muſt be ſo adjuſted, that the work performed, divided by the *whole* time of the working and returning ſtrokes, may give the greateſt quotient. It is ſtill a difficult thing, therefore, to conſtruct a machine in the moſt perfect manner, or even to ſay what will be the performance of a machine already conſtructed; yet we ſee that every circumſtance is ſuſceptible of accurate computation.

With reſpect to machines which acquire a ſort of uniform motion in general, although ſubject to partial reciprocations, as in a pumping, ſtamping, forging engine, it is alſo difficult to aſſign the rate even of this general uniform motion. We may, however, ſay, that it will not be greater than if it were uniform throughout. Were it entirely free from friction, it would be exactly the ſame as if uniform; becauſe the accelerations during the advantageous ſituations of the impelling power would compenſate the retardations. But friction diminiſhes the accelarations, without diminiſhing the retardations.

We may conclude this article with ſome obſervations tending to the general improvement of machines.

33 Uniformity of motion [illegible] of great advantage. Nothing contributes more to the per[illegible] a ma-[illegible] tion waſtes ſome of the impelling power; and it is only the greateſt of the varying velocities which is equal to that which the machine would acquire if moving uniformly throughout; for, while the motion accelerates, the impelling force is greater than what balances the reſiſtance then actually oppoſed to it, and the velocity is leſs than what the machine would acquire if moving uniformly: and when the machine attains its greateſt velocity, it attains it becauſe the power is then not acting againſt the whole reſiſtance. In both of theſe ſituations, therefore, the performance of the machine is leſs than if the power and reſiſtance were exactly balanced; in which caſe it would move uniformly.

34 How to attain this. Every attention ſhould therefore be given to this, and we ſhould endeavour to remove all cauſe of irregularity. The communications of motion ſhould be ſo contrived, that if the impelled point be moving uniformly, by the uniform preſſure of the power, the working point ſhall alſo be moving uniformly. Then we may generally be certain, that the maſſy parts of the machine will be moving uniformly. When this is not done through the whole machine, there are continual returns of ſtrains and jolts; the inertia of the different parts acting in oppoſite directions. Although the whole momenta may always balance each other, yet the general motion is hobbling, and the points of ſupport are ſtrained. A great engine ſo conſtructed, commonly cauſes the building to tremble; but when uniform motion pervades the whole machine, the inertia of each part tends to preſerve this uniformity, and all goes ſmoothly. It is alſo deſerving of remark, that when the communications are ſo con[illegible]d that the motion of one part produces uniform motion on the next, the preſſures at the communicating points remain conſtant or invariable. Now the accompliſhing of this is always within the reach of mechanics.

35 Beſt forms for the teeth of wheels Plate XXXIII. fig. 1. One of the moſt uſual communications in machinery is by means of toothed wheels acting on each other. It is of importance to have the teeth ſo formed, that the preſſure by which one of them A urges the other B round its axis ſhall be conſtantly the ſame. It can eaſily be demonſtrated, that when this is the caſe, the uniform angular motion of the one will produce a uniform angular motion of the other; or, if the motions are thus uniform, the preſſures are invariable. This is accompliſhed on this principle, that the mutual actions of ſolid bodies on each other in the way of preſſure are perpendicular to the touching ſurfaces. Therefore let the tooth a preſs on the tooth b in the point C; and draw the line FCDE perpendicular to the touching ſurfaces in the point C. Draw AF, BE perpendicular to FE, and let FE cut the line AB in D. It is plain, from the common principles of mechanics, that if the line FE, drawn in the manner now deſcribed, always paſs through the ſame point D, whatever may be the ſituation of the acting teeth, the mutual action of the wheels will always be the ſame. It will be the ſame as if the arm AD acted on the arm BD. In the treatiſes on the conſtruction of mills, and other works of this kind, are many inſtructions for the formation of the teeth of wheels; and almoſt every noted millwright has his own noſtrums. Moſt of them are egregiouſly faulty in reſpect of mechanical principle. Indeed they are little elſe than inſtructions how to make the teeth clear each other without ſticking. Mr de la Hire firſt pointed out the above mentioned principle, and juſtly condemned the common practice of making the ſmall wheel or pinion in the form of a lantern (whence it alſo took its name), conſiſting of two round diſks, having a number of cylindrical ſpokes (fig. 2.) The ſlighteſt inſpection of this conſtruction ſhews, that, in the different ſituations of the working teeth, the line FCE continually changes its interſection with AB. If the wheel B be very ſmall in compariſon of the other, and if the teeth of A take deep hold of the cylindrical pins of B, the line of action EF is ſometimes ſo diſadvantageouſly placed, that the preſſure of the one wheel has ſcarcely any tendency at all to turn the other. Mr de la Hire, or Dr Hooke, was, we think, the firſt who inveſtigated the form of a tooth which procured this conſtant action between the wheels; and in a very ingenious diſſertation, publiſhed among the Memoirs of the Academy of Sciences at Paris 1668, the former of theſe gentlemen ſhews, that this will be enſured by forming the teeth into epicycloids. Epicycloid teeth by De la Hire. Mr Camus of the ſame Academy has publiſhed an elaborate diſſertation on the ſame ſubject, in which he proſecutes the principle of Mr de la Hire, and applies it to all the variety of caſes which can occur in practice. There is no doubt as to the goodneſs of the principle; and it has another excellent property, "that the mutual action of the teeth is abſolutely without any friction." The one tooth only applies itſelf to the other, and rolls on it, but does not ſlide or rub in the ſmalleſt degree. This makes them laſt long, or rather does not allow them to wear in the leaſt. But the conſtruction is ſubject to a limitation which muſt not be neglected. The teeth muſt be ſo made, that the curved part of the tooth b is acted on by a flat part of the tooth a till it comes to the line AB in the courſe of its action; after which

which the curved part of a acts on a flat part of b; or the whole action of a on b is either completed, or only begins at the line AB, joining the centres of the wheels.

36
A better form.

Another form of the teeth secures the perfect uniformity of action without this limitation, which requires very nice execution. Let the teeth of each wheel be formed by evolving its circumference; that is, let the acting face GCH of the tooth a have the form of the curve traced by the extremity of the thread FC, unlapped from the circumference. In like manner, let the acting face of the tooth b be formed by unlapping a thread from its circumference. It is evident, that the line FCE, which is drawn perpendicularly to the touching surfaces in the point C, is just the direction or position of the evolving threads by which the two acting faces are formed. This line must therefore be the common tangent to the two circles or circumferences of the wheels, and will therefore always cut the line AB in the same point D. This form allows the teeth to act on each other through the whole extent of the line FCE, and therefore will admit of several teeth to be acting at the same time (twice the number that can be admitted in Mr de la Hire's method). This, by dividing the pressure among several teeth, diminishes its quantity on any one of them, and therefore diminishes the dents or impressions which they unavoidably make on each other. It is not altogether free from sliding and friction, but the whole of it can hardly be said to be sensible. The whole slide of a tooth three inches long, belonging to a wheel of ten feet diameter, acting on a tooth of a wheel of two feet diameter, does not amount to $\frac{1}{20}$th of an inch, a quantity altogether insignificant.

In the formation of the teeth of wheels, a small deviation from these perfect forms is not perhaps of very great importance, except in cases where a very large wheel drives a very small one (a thing which a good engineer will always avoid). As the construction, however, is exceedingly easy, it would be unpardonable to omit it. Well formed teeth, and a great number of them acting at once, make the communication of motion extremely smooth and uniform. The machine works without noise, and the teeth last a very long time without sensibly changing their shape. But there are cases, such as the pallets of clocks and watches, where the utmost accuracy of form is of the greatest importance for the perfection of the work.

37
Maxim for the construction of stampers, &c.

When heavy stampers are to be raised, in order to drop on the matters to be pounded, the wipers by which they are lifted should be made of such a form, that the stamper may be raised by a uniform pressure, or with a motion almost perfectly uniform. If this is not attended to, and the wiper is only a pin sticking out from the axis, the stamper is forced into motion at once. This occasions violent jolts to the machine, and great strains on its moving parts and their points of support; whereas when they are gradually lifted, the inequality of desultory motion is never felt at the impelled point of the machine. We have seen pistons moved by means of a double rack on the piston rod. A half wheel takes hold of one rack, and raises it to the required height. The moment the half wheel has quitted that side of the rack, it lays hold of the other side, and forces the piston down again. This is proposed as a great improvement; correcting the unequable motion of the piston moved in the common way by a crank. But it is far inferior to the crank motion. It occasions such abrupt changes of motion, that the machine is shaken by jolts. Indeed if the movement were accurately executed, the machine would be shaken to pieces, if the parts did not give way by bending and yielding. Accordingly, we have always observed that this motion soon failed, and was changed for one that was more smooth. A judicious engineer will avoid all such sudden changes of motion, especially in any ponderous part of a machine.

When several stampers, pistons, or other reciprocal movers, are to be raised and depressed, common sense teaches us to distribute their times of action in a uniform manner, so that the machine may always be equally loaded with work. When this is done, and the observations in the preceding paragraph attended to, the machine may be made to move almost as smoothly as if there were no reciprocations in it. Nothing shews the ingenuity of the author more than the artful yet simple and effectual contrivances for obviating those difficulties that unavoidably arise from the very nature of the work that must be performed by the machine, and of the power employed. The inventive genius and found judgment of Watt and Boulton are as perceptible to a skilled observer in these subordinate parts of some of their great engines, as in the original discovery on which their patent is founded. In some of those engines the mass of dead matter which must be put into motion, and this motion destroyed and again restored in every stroke, is enormous, amounting to above an hundred tons. The ingenious authors have even contrived to draw some advantages from it, by allowing a great want of equilibrium in certain positions; and this has been condemned as a blunder by engineers who did not see the use made of it.

There is also great room for ingenuity and good choice in the management of the moving power, when it is such as cannot immediately produce the kind of motion required for effecting the purpose. We mentioned the conversion of the continued rotation of an axis into the reciprocating motion of a piston, and the improvement which was thought to have been made on the common and obvious contrivance of a crank, by substituting a double rack on the piston rod, and the inconvenience arising from the jolts occasioned by this change. We have seen a great forge, where the engineer, in order to avoid the same inconvenience arising from the abrupt motion given to the great sledge hammer of seven hundred weight, resisting with a five-fold momentum, formed the wipers into spirals, which communicated motion to the hammer almost without any jolt whatever; but the result was, that the hammer rose no higher than it had been raised in contact with the wiper, and then fell on the iron bloom with very little effect. The cause of its inefficiency was not guessed at; but it was removed, and wipers of the common form were put in place of the spirals. In this operation, the rapid motion of the hammer is absolutely necessary. It is not enough to *lift* it up; it must be *tossed* up, so as to fly higher than the wiper lifts it, and to strike with great force the strong oaken spring which is placed in its way. It compresses this spring, and is reflected by it with a considerable velocity, so as to hit the iron as if it had fallen from a great height. Had

38
The unavoidable inequalities of moving power must be compensated by the construction.

it been allowed to fly to that height, it would have fallen upon the iron with ſomewhat more force (becauſe no oaken ſpring is perfectly elaſtic); but this would have required more than twice the time.

38 Great inconveniences of a reciprocating power.

In employing a power which of neceſſity reciprocates, to drive machinery which requires a continuous motion (as in applying the ſteam engine to a cotton or a griſt mill), there alſo occur great difficulties. The neceſſity of reciprocation in the firſt mover waſtes much power; becauſe the inſtrument which communicates ſuch an enormous force muſt be extremely ſtrong, and be well ſupported. The impelling power is waſted in imparting, and afterwards deſtroying, a vaſt quantity of motion in the working beam. The ſkilful engineer will attend to this, and do his utmoſt to procure the neceſſary ſtrength of this firſt mover, without making it a vaſt load of inert matter. He will alſo remark, that all the ſtrains on it, and on its ſupports, are changing their directions in every ſtroke. This requires particular attention to the manner of ſupporting it. If we obſerve the ſteam engines which have been long erected, we ſee that they have uniformly ſhaken the building to pieces. This has been owing to the ignorance or inattention of the engineer in this particular. They are much more judiciouſly erected now, experience having taught the moſt ignorant that no building can withſtand their deſultory and oppoſite jolts, and that the great movements muſt be ſupported by a framework independent of the building of maſonry which contains it (N).

The engineer will alſo remark, that when a ſingle ſtroke ſteam engine is made to turn a mill, all the communications of motion change the direction of their preſſure twice every ſtroke. During the working ſtroke of the beam, one ſide of the teeth of the intervening wheels is preſſing the machinery forward; but during the returning ſtroke, the machinery, already in motion, is dragging the beam, and the wheels are acting with the other ſide of the teeth. This occaſions a rattling at every change, and makes it proper to faſhion both ſides of the teeth with the ſame care.

It will frequently conduce to the good performance of an engine, to make the action of the reſiſting work unequable, accommodated to the inequalities of the impelling power. This will produce a more uniform motion in machines in which the momentum of inertia is inconſiderable. There are ſome beautiful ſpecimens of this kind of adjuſtment in the mechaniſm of animal bodies.

39 ure, &c. ation, le of FLY.

It is very cuſtomary to add what is called a FLY to machines. This is a heavy diſk or hoop, or other maſs of matter, *balanced on its axis*, and ſo connected with the machinery as to turn briſkly round with it. This may be done with the view of rendering the motion of the whole more regular, notwithſtanding unavoidable inequalities of the accelerating forces, or of the reſiſtances occaſioned by the work. It becomes a REGULATOR. Suppoſe the reſiſtance extremely unequal, and the impelling power perfectly conſtant; as when a bucket wheel is employed to work *one* pump. When the piſton has ended its working ſtroke, and while it is going down the barrel, the power of the wheel being ſcarcely oppoſed, it accelerates the whole machine, and the piſton arrives at the bottom of the barrel with a conſiderable velocity. But in the riſing again, the wheel is oppoſed by the column of water now preſſing on the piſton. This immediately retards the wheel; and when the piſton has reached the top of the barrel, all the acceleration is undone, and is to begin again. The motion of ſuch a machine is very hobbling: but the ſuperplus of accelerating force at the beginning of a returning ſtroke will not make ſuch a change in the motion of the machine if we connect the fly with it. For the accelerating momentum is a determinate quantity. Therefore, if the radius of the fly be great, this momentum will be attained by communicating a ſmall angular motion to the machine. The momentum of the fly is as the ſquare of its radius; therefore it reſiſts acceleration in this proportion; and although the overplus of power generates the ſame momentum of rotation in the whole machine as before, it makes but a ſmall addition to its velocity. If the diameter of the fly be doubled, the augmentation of rotation will be reduced to one-fourth. Thus, by giving a rapid motion to a ſmall quantity of matter, the great acceleration during the returning ſtroke of the piſton is prevented. This acceleration continues, however, during the whole of the returning ſtroke, and at the end of it the machine has acquired its greateſt velocity. Now the working ſtroke begins, and the overplus of power is at an end. The machine accelerates no more; but if the power is juſt in equilibrio with the reſiſtance, it keeps the velocity which it has acquired, and is ſtill more accelerated during the *next* returning ſtroke. But now, at the beginning of the ſubſequent working ſtroke, there is an overplus of reſiſtance, and a retardation begins, and continues during the whole rise of the piſton; but it is inconſiderable in compariſon of what it would have been without the fly; for the fly, retaining its acquired momentum, drags forward the reſt of the machine, aiding the impelling power of the wheel. It does this by all the communications taking into each other in the oppoſite direction. The teeth of the intervening wheels are heard to drop from their former contact on one ſide, to a contact on the other. By conſidering this proceſs with attention, we eaſily perceive that, in a few ſtrokes, the overplus of power during the returning ſtroke comes to be ſo adjuſted to the deficiency during the working ſtroke, that the accelerations and retardations exactly deſtroy each other, and every ſucceeding ſtroke is made with the ſame velocity, and an equal number of ſtrokes is made in every ſucceeding minute. Thus the machine acquires a general uniformity with periodical inequalities. It is plain, that by ſufficiently enlarging either the diameter or the weight

(N) The gudgeons of a water-wheel ſhould never reſt on the wall of the building. It ſhakes it; and if ſet up ſoon after the building has been erected, it prevents the mortar from taking firm bond; perhaps by ſhattering the calcareous cryſtals as they form. When the engineer is obliged to reſt the gudgeons in this way, they ſhould be ſupported by a block of oak laid a little hollow. This ſoftens all tremors, like the ſprings of a wheel carriage. This practice would be very ſerviceable in many other parts of the conſtruction.

weight of the fly, the irregularity of the motion may be rendered as small as we please. It is much better to enlarge the diameter. This preserves the friction more moderate, and the pivot wears less. For these reasons, a fly is in general a considerable improvement in machinery, by equalising many exertions that are naturally very irregular. Thus, a man working at a common windlass, exerts a very irregular pressure on the winch. In one of his positions in each turn he can exert a force of near 70 pounds without fatigue, but in another he cannot exert above 25; nor must he be loaded with much above this in general. But if a large fly be connected properly with the windlass, he will act with equal ease and speed against 30 pounds.

40 It is a powerful regulator.

This regulating power of the fly is without bounds, and may be used to render uniform a motion produced by the most desultory and irregular power. It is thus that the most regular motion is given to mills that are driven by a single stroke steam engine, where for two or even three seconds there is no force pressing round the mill. The communication is made through a massive fly of very great diameter, whirling with great rapidity. As soon as the impulse ceases, the fly, continuing its motion, urges round the whole machinery with almost unabated speed. At this instant all the teeth, and all the joints, between the fly and the first mover, are heard to catch in the opposite direction.

If any permanent change should happen in the impelling power, or in the resistance, the fly makes no obstacle to its producing its full effect on the machine; and it will be observed to accelerate or retard uniformly, till a new general speed is acquired exactly corresponding with this new power and resistance.

Many machines include in their construction movements which are equivalent with this intentional regulator. A flour mill, for example, cannot be better regulated than by its millstone; but in the Albion mills, a heavy fly was added with great propriety; for if the mills had been regulated by their millstones only, then at every change of stroke in the steam engine, the whole train of communications between the beam, which is the first mover, and the regulating millstone, which is the very last mover, would take in the opposite direction. Although each drop in the teeth and joints be but a trifle, the whole, added together, would make a considerable jolt. This is avoided by a regulator immediately adjoining to the beam. This continually presses the working machinery in one direction. So judiciously were the movements of that noble machine contrived, and so nicely were they executed, that not the least noise was heard, nor the slightest tremor felt in the building.

* See Pile Engine, Encycl.

Mr Valoué's beautiful pile engine employed at Westminster Bridge is another remarkable instance of the regulating power of a fly*. When the ram is dropped, and its follower disengaged immediately after it, the horses would instantly tumble down, because the load, against which they had been straining hard, is at once taken off; but the gin is connected with a very large fly, which checks any remarkable acceleration, allowing the horses to lean on it during the descent of the load; after which their draught recommences immediately. The spindles, cards, and bobbins, of a cotton mill, are also a sort of flies. Indeed all bulky machines of the rotative kind tend to preserve their motion with some degree of steadiness, and their great momentum of inertia is as useful in this respect as it is prejudicial to the acceleration or any reciprocation, when wanted.

41 A bad construction of a fly.

There is another kind of regulating fly, consisting of wings whirled briskly round till the resistance of the air prevents any great acceleration. This is a very bad one for a *working* machine, for it produces its effect by *really wasting* a part of the moving power. Frequently it employs a very great and unknown part of it, and robs the proprietor of much work. It should never be introduced into any machine employed in manufactures.

42 A conical pendulum is the most perfect regulator.

Some rare cases occur where a very different regulator is required; where a certain determined velocity is found necessary. In this case the machine is furnished, at its extreme mover, with a conical pendulum, consisting of two heavy balls hanging by rods, which move in very nice and steady joints at the top of a vertical axis. It is well known, that when this axis turns round, with an angular velocity suited to the length of those pendulums, the time of a revolution is determined. Thus, if the length of each pendulum be $39\frac{1}{4}$ inches, the axis will make a revolution in two seconds very nearly. If we attempt to force it more swiftly round, the balls will recede a little from the axis, but it employs as long time for a revolution as before; and we cannot make it turn swifter, unless the impelling power be increased beyond all probability; in which case the pendulum will fly out from the centre till the rods are horizontal, after which every increase of power will accelerate the machine very sensibly. W[illegible] this contrivance with great [illegible] gines, when they are empl[illegible] [illegible]ing machinery [illegible] manufactures which have a very [illegible]ingeable resist[illegible] and where a certain speed cannot be much departed from without great inconvenience. They have connected this recess of the balls from the axis (which gives immediate indication of an increase of power or a diminution of resistance) with the cock which admits the steam to the working cylinder. The balls flying out, cause the cock to close a little, and diminish the supply of steam. The impelling power diminishes the next moment, and the balls again approach the axis, and the rotation goes on as before, although there may have occurred a very great excess or deficiency of power. The same contrivance may be employed to raise or lower the feeding sluice of a water mill employed to drive machinery.

43 A fly sometimes collects power

A fly is sometimes employed for a very different purpose from that of a regulator of motion—it is employed as a *collector of power*. Suppose all resistance removed from the working point of a machine furnished with a very large or heavy fly immediately connected with the working point. When a small force is applied to the impelled point of this machine, motion will begin in the machine, and the fly begin to turn. Continue to press uniformly, and the machine will accelerate. This may be continued till the fly has acquired a very rapid motion. If at this moment a resisting body be applied to the working point, it will be acted on with very great force; for the fly has now accumulated in its circumference a very great momentum. If a body were exposed immediately to the action of this circumference, it would be violently struck. Much more will it be so, if the body be exposed to the action of the

working

working point, which perhaps makes one turn while the fly makes a hundred. It will exert a hundred times more force there (very nearly) than at its own circumference. All the motion which has been accumulated on the fly during the whole progress of its acceleration is exerted in an instant at the working point, multiplied by the momentum depending on the proportion of the parts of the machine. It is thus that the coining press performs its office; nay, it is thus that the blacksmith forges a bar of iron. Swinging the great sledge hammer round his head, and urging it with force the whole way, this accumulated motion is at once extinguished by impact on the iron. It is thus we drive a nail; and it is thus that by accumulating a very moderate force exerted during four or five turns of a fly, the whole of it is exerted on a punch set on a thick plate of iron, such as is employed for the boilers of steam engines. The plate is pierced as if it were a bit of cheese. This accumulating power of a fly has occasioned many who think themselves engineers to imagine, that a fly really adds power or mechanical force to an engine; and, not understanding on what its efficacy depends, they often place the fly in a situation where it only added a useless burden to the machine. It should always be made to move with rapidity. If intended for a mere regulator, it should be near the first mover. If it is intended to accumulate force in the working point, it should not be far separated from it. In a certain sense, a fly may be said to add power to a machine, because by accumulating into the exertion of one moment the exertions of many, we can sometimes overcome an obstacle that we never could have balanced by the same machine unaided by the fly.

It is this accumulation of force which gives such an appearance of power to some of our first movers. When a man is unfortunately catched by the teeth of a paltry country mill, he is crushed almost to mummy. The power of the stream is conceived to be prodigious; and yet we are certain, upon examination, that it amounts to the pressure of no more than fifty or sixty pounds. But it has been acting for some time; and there is a millstone of a ton weight whirling twice round in a second. This is the force that crushed the unfortunate man; and it required it all to do it, for the mill stopped. We saw a mill in the neighbourhood of Elbingroda in Hanover, where there was a contrivance which disengaged the millstone when any thing got entangled in the teeth of the wheels. It was tried in our sight with a head of cabbage. It crushed it indeed, but not violently, and would by no means have broken a man's arm.

44 plicity onstruc recom- ded.

It is hardly necessary to recommend simplicity in the construction of machines. This seems now sufficiently understood. Multiplicity of motions and communications increases frictions; increases the unavoidable losses by bending and yielding in every part; exposes to all the imperfections of workmanship; and has a great chance of being indistinctly conceived, and therefore constructed without science. We think the following construction of a capstan or crab a very good example of the advantages of simplicity. It is the invention of an untaught but very ingenious country tradesman.

3. EAB is the barrel of the capstan, standing vertically in a proper frame, as usual, and urged round by bars such as EF. The upper part A of the barrel is 17 inches in diameter, and the lower B is 16. C is a strong pulley 16 inches in diameter, having a hook D, which takes hold of a hawser attached to the load. The rope ACB is wound round the barrel A, passes over the pulley C, and is then wound round the barrel B in the opposite direction. No farther description is necessary, we think, to shew that, by heaving by the bar F, so as to wind more of the rope upon A, and unwind it from B, the pulley C must be brought nearer to the capstan by about three inches for each turn of the capstan; and that this simple capstan is equivalent to an ordinary capstan of the same length of bar EF, and diameter of barrel B, combined with a 16 fold tackle of pulleys; or, in short, that it is 16 times more powerful than the common capstan; free from the great loss by friction and bending of ropes, which would absorb a third of the power of a 16 fold tackle; and that whereas all other engines become weaker as they multiply the power to a greater degree (unless they are proportionally more bulky), this engine becomes really stronger in itself. Suppose we wanted to have it twice as powerful as at present; nothing is necessary but to cover the part B of the barrel with laths a quarter of an inch thick. In short, the nearer the two barrels are to equality, the more powerful does it become. We give it to the public as an excellent capstan, and as suggesting thoughts which an intelligent engineer may employ with great effect. By this contrivance, and using an iron wire instead of a catgut, we converted a common eight day clock into one which goes for two months.

45 Example of a very simple and powerful capstan.

We intended to conclude this article with some observations on the chief classes of powers which are employed to drive machinery; such as water, wind, atmospheric pressure, gunpowder, and the force of men and other animals, giving some notion of their absolute magnitudes, and the effect which may be expected from them. We should then have mentioned what has been discovered as to their variation by a variation of velocity. And we intended to conclude with an account of what knowledge has been acquired concerning friction, and the loss of power in machinery arising from this cause, and from the stiffness of ropes, and some other causes: But we have not yet been able to bring these matters into a connected form, which would suggest the methods and means of farther information thereon. We must endeavour to find another opportunity of communicating to the public what we may yet learn on those subjects.

We have now established the principles on which machines must be constructed, in order that they may produce the greatest effect; but it would be improper to dismiss the subject without stating to our readers Mr Bramah's new method of producing and applying a more considerable degree of power to all kinds of machinery requiring motion and force, than by any means at present practised for that purpose. This method, for which on the 31st of March 1796 he obtained a patent, consists in the application of water or other dense fluids to various engines, so as, in some instances, to

to cause them to act with immense force; in others, to communicate the motion and powers of one part of a machine to some other part of the same machine; and, lastly, to communicate the motion and force of one machine to another, where their local situations preclude the application of all other methods of connection.

The first and most material part of this invention will be clearly understood by an inspection of fig. 4. where "A is a cylinder of iron, or other materials, sufficiently strong, and bored perfectly smooth and cylindrical; into which is fitted the piston B, which must be made perfectly water-tight, by leather or other materials, as used in pump-making. The bottom of the cylinder must also be made sufficiently strong with the other part of the surface, to be capable of resisting the greatest force or strain that may at any time be required. In the bottom of the cylinder is inserted the end of the tube C; the aperture of which communicates with the inside of the cylinder, under the piston B, where it is shut with the small valve D, the same as the suction-pipe of a common pump. The other end of the tube C communicates with the small forcing pump or injector E, by means of which water or other dense fluids can be forced or injected into the cylinder A, under the piston B. Now, suppose the diameter of the cylinder A to be 12 inches, and the diameter of the piston of the small pump or injector E only one quarter of an inch, the proportion between the two surfaces or ends of the said pistons will be as 1 to 2304; and supposing the intermediate space between them to be filled with water or other dense fluid capable of sufficient resistance, the force of one piston will act on the other just in the above proportion, viz. as 1 is to 2304. Suppose the small piston in the injector to be forced down when in the act of pumping or injecting water into the cylinder A, with the power of 20 cwt. which could easily be done by the lever H; the piston B would then be moved up with a force equal to 20 cwt. multiplied by 2304. Thus is constructed a hydro-mechanical engine, whereby a weight amounting to 2304 tons can be raised by a simple lever, through equal space, in much less time than could be done by any apparatus constructed on the known principles of mechanics; and it may be proper to observe, that the effect of all other mechanical combinations is counteracted by an accumulated complication of parts, which renders them incapable of being usefully extended beyond a certain degree; but in machines acted upon or constructed on this principle, every difficulty of this kind is obviated, and their power subject to no finite restraint. To prove this, it will be only necessary to remark, that the force of any machine acting upon this principle can be increased *ad infinitum*, either by extending the proportion between the diameter of the injector and the cylinder A, or by applying greater power to the lever H.

"Fig 5. represents the section of an engine, by which very wonderful effects may be produced instantaneously by means of compressed air. AA is a cylinder, with the piston B fitting air-tight, in the same manner as described in fig. 4. C is a globular vessel made of copper, iron, or other strong materials, capable of resisting immense force, similar to those of air guns. D is a strong tube of small bore, in which is the stop-cock E. One of the ends of this tube communicates with the cylinder under the piston B, and the other with the globe C. Now, suppose the cylinder A to be the same diameter as that in fig. 4. and the tube D equal to one quarter of an inch diameter, which is the same as the injector fig. 4.: then, suppose that air is injected into the globe C (by the common method), till it presses against the cock E with a force equal to 20 cwt. which can easily be done; the consequence will be, that when the cock E is opened, the piston B will be moved in the cylinder AA with a power or force equal to 2304 tons; and it is obvious, as in the case fig. 4. that any other unlimited degree of force may be acquired by machines or engines thus constructed.

"Fig. 6. is a section, merely to shew how the power and motion of one machine may, by means of fluids, be transferred or communicated to another, let their distance and local situation be what they may. A and B are two small cylinders, smooth and cylindrical; in the inside of each of which is a piston, made water and air tight, as in figs 4. and 5. CC is a tube conveyed under ground, or otherwise, from the bottom of one cylinder to the other, to form a communication between them, notwithstanding their distance be ever so great; this tube being filled with water or other fluid, until it touch the bottom of each piston; then, by depressing the piston A, the piston B will be raised. The same effect will be produced *vice versa*: thus bells may be rung, wheels turned, or other machinery put invisibly in motion, by a power being applied to either.

"Fig. 7. is a section, shewing another instance of communicating the action and force of one machine to another; and how water may be raised out of wells of any depth, and at any distance from the place where the operating power is applied. A is a cylinder of any required dimensions, in which is the working piston B, as in the foregoing examples: into the bottom of this cylinder is inserted the tube C, which may be of less bore than the cylinder A. This tube is continued, in any required direction, down to the pump cylinder D, supposed to be fixed in the deep well EE, and forms a junction therewith above the piston F; which piston has a rod G, working through the stuffing-box, as is usual in a common pump. To this rod G is connected, over a pulley or otherwise, a weight H, sufficient to overbalance the weight of the water in the tube C, and to raise the piston F when the piston B is lifted: thus, suppose the piston B is drawn up by its rod, there will be a vacuum made in the pump cylinder D, below the piston F; this vacuum will be filled with water through the suction pipe, by the pressure of the atmosphere, as in all pumps fixed in air. The return of the piston B, by being pressed downwards in the cylinder A, will make a stroke of the piston in the pump cylinder D, which may be repeated in the usual way by the motion of the piston B, and the action of the water in the tube C. The rod G of the piston F, and the weight H, are not necessary in wells of a depth where the atmosphere will overbalance the water in the suction of the pump cylinder D, and that in the tube C. The small tube and cock in the cistern I, are for the purpose of charging the tube C."

That these contrivances are ingenious, and may occasionally prove useful, we are not inclined to controvert; but we must confess, that the advantages of them appear

appear not to us so great as to their author. Why they do not, we need not explain to any man who, with a sufficient degree of mechanical and mathematical knowledge, has perused this article with attention. *Mr John Luccock*, however, of Marley, near Leeds, thinks so very differently from us on this subject, that, on Mr Bramah's principle, he proposes to apply water or other dense fluids, so as to make them supply the place of steam in what is commonly called the *steam engine*. He calls his engine the *paradoxical machine*; and he got a patent for it on the 28th of February 1799, though it differs in nothing from Mr Bramah's machine, represented by fig. 4. except that the tube C in the paradoxical machine is supplied with water, not by means of a forcing pump, but from a cistern elevated to such a height as, that the water descending through the tube may produce its effect merely by its weight. Whether this variation, for it is no improvement, of Mr Bramah's machine intitled its author to a patent, it is not our business to inquire.

Macpherson.

MACPHERSON (James, Esq;), was born in the parish of Kingusie, and county of Inverness, in the year 1738. His father was a farmer of no great affluence; and young Macpherson received the earlier part of his education in one of the parish schools in the district called Badenoch. By an anonymous writer in the Edinburgh Magazine, he is said to have been educated in the grammar school of Inverness; and he may, for ought that we know to the contrary, have spent a year in that seminary; but we rather think that he went directly from a country school to the university of Aberdeen. At this our readers need not be surprised; for at the period to which we refer, some of the parochial schoolmasters in Scotland, and more especially in the Highlands, were men eminent for taste and classical literature.

It was in the end of October or the 1st of November 1752, that James Macpherson entered the King's College; where he displayed more genius than learning, entertaining the society of which he was a member, and even diverting the younger part of it from their studies, by his humorous and doggerel rhimes. About two years after his admission into the university, the King's College added two months to the length of its annual *session* or *term*; which induced Macpherson, with many other young men, to remove to the Marischal College, where the session continued short; and it is this circumstance which leads us to suppose that his father was not opulent.

Soon after he left college, and perhaps before he left it, he was schoolmaster of Ruthven, or Riven, of Badenoch; and we believe he afterwards delighted as little as his great antagonist Johnson in the recollection of that period when he was compelled, by the narrowness of his fortune, to teach boys in an obscure school. It was during this period, we think in 1758, that he published *The Highlander*, an heroic poem in six cantos, 12mo. Of this work, as we have never seen it, we can say nothing. By the anonymous writer already quoted, it is mentioned as a "tissue of fustian and absurdity;" whilst others, and they too men of learning and character, have assured us, that it indicated considerable genius in so young an author.

Soon after this publication, Mr Macpherson quitted his school, and was received by Mr Graham of Balgowan into his family as tutor to his sons; an employment of which he was not fond, and to which he was not long condemned. In the year 1760 he surprised the world by the publication of *Fragments of Ancient Poetry, collected in the Highlands of Scotland, and Translated from the Gaelic or Erse Language*, 8vo. These fragments, which were declared to be genuine remains of ancient Scottish poetry, at their first appearance delighted every reader; and some very good judges, and amongst the rest Mr Gray, were extremely warm in their praises. Macpherson had intended to bury them in a Scotch magazine, but was prevented from so injudicious a step by the advice of a friend. He published them therefore in a pamphlet by themselves, and thus laid the foundation of his future fortune.

Macpherson.

As other specimens were said to be recoverable, a subscription was set on foot by the Faculty of Advocates at Edinburgh, to enable our author to quit the family of Balgowan, perambulate the Highlands, and secure, if he could, the precious treasure. He engaged in the undertaking, and was successful; for all who possessed any of the long famed works, vied with each other in giving or sending them to a man who had shewn himself so capable of doing them justice.

With his collection of poems, and fragments of poems, he went to London; and tagging them together in the form which he thought best, he published, in 1762, *Fingal, an Ancient Epic Poem, in six books*, together with several other poems, composed by Ossian the son of Fingal, translated from the Gaelic language. 4to. The subject of this epic poem is an invasion of Ireland by Swaran king of Lochlin. Cuchullin, general of the Irish tribes during the minority of Cormac king of Ireland, upon intelligence of the invasion, assembled his forces near Tura, a castle on the coast of Ulster. The poem opens with the landing of Swaran; councils are held, battles fought, and Cuchullin is at last totally defeated. In the mean time, Fingal, king of the Highlands of Scotland, whose aid had been solicited before the enemy landed, arrived, and expelled them from the country. This war, which continued but six days and as many nights, is, including the episodes, the story of the Poem. The scene, the heath of Lena, near a mountain called Cromleach in Ulster. This poem also was received with equal applause as the preceding Fragments.

The next year he produced *Temora*, an ancient epic poem, in eight books; together with several other poems composed by Ossian son of Fingal, 4to, which, though well received, found the public somewhat less disposed to bestow the same measure of applause. Tho' these poems had been examined by Dr Blair and others, and their authenticity asserted, there were not wanting some of equal reputation for critical abilities, who either doubted or declared their disbelief of the genuineness of them.

Macpherson.

them. Into this question it would be superfluous to enter here particularly, as we have said enough on it elsewhere. See Ossian, *Encycl.*

That any man should suppose Macpherson, after his translation of Homer, the *author* of the poems which he ascribes to Ossian, appears to us very extraordinary; and it is little less extraordinary, that any one should, for a moment, believe in the existence of *manuscripts* of these poems of *very high* antiquity. Part of them he undoubtedly received in manuscript from Macdonald of Clanronald; but we can affirm, on the best authority, that the said manuscript was written at different times by the Macvuirichs, hereditary bards to that family. He may likewise have received short manuscripts elsewhere; but every Highland gentleman of learning and of candour (and none else have a right to decide on this question), declares, that by much the greater part of the poems had been preserved in fragments and popular songs from a very remote age by oral tradition. To these fragments Macpherson and his associates (A) gave form; and it was by uniting together fragments of different ages, that he inadvertently furnished Gibbon and others with the opportunity of objecting, that the poems are sometimes inconsistent with the truth of history. This, however, is no solid objection to their authenticity; for every West Highlander fifty years of age remembers to have heard, in his youth, great part of those poems repeated by old men; and is confident that, many centuries ago, the names of *Fion Mackuil* (Fingal), and of Ossian's other heroes and heroines, were as familiar to a Highland ear, as the names of Agamemnon, Hector, Helen, &c. were to a Grecian ear at the time when the poems of Homer were reduced into their present form. For the substance of the poems, this is such evidence as none will reject who does not prefer his own cobweb theories to the united testimony of a whole people.

With respect to authenticity, the poems of Ossian have indeed been compared with the poems of Rowley; but the comparison is absurd. The poems of the Celtic bard were not found in an old chest, and presented to a people who had never before heard either of them or of their author; they were the popular songs and traditions of ages collected together, and reduced into form, with additions occasionally made by the translator. It is ridiculous to ask how these songs and stories could be so long preserved among a rude and illiterate people; for it is only among such a people, whose objects of pursuit are too few to occupy all their attention, that the exploits of their ancestors can be handed down by tradition; and the most serious objection which we have ever met with to the translator's account of the origin of the poems, arises from his having pretended that he received the greater part of them in old manuscripts.

After the publication of Ossian's poems, by which we have reason to believe that he gained twelve hundred pounds, Mr Macpherson was called to an employment which withdrew him, for some time, both from the muses and from his country. Captain Johnstone was appointed governor of Pensacola, and Mr Macpherson accompanied him as his secretary, being at the same time made surveyor general of the Floridas. If our memory does not deceive us, some difference arose between the principal and his dependant, and they parted before their return to England. Having contributed his aid to the settlement of the civil government of that colony, he visited several of the West India islands, and some of the provinces of North America, and returned to England in the year 1766, where he retained for life his salary as surveyor, which we believe was L. 200 a year.

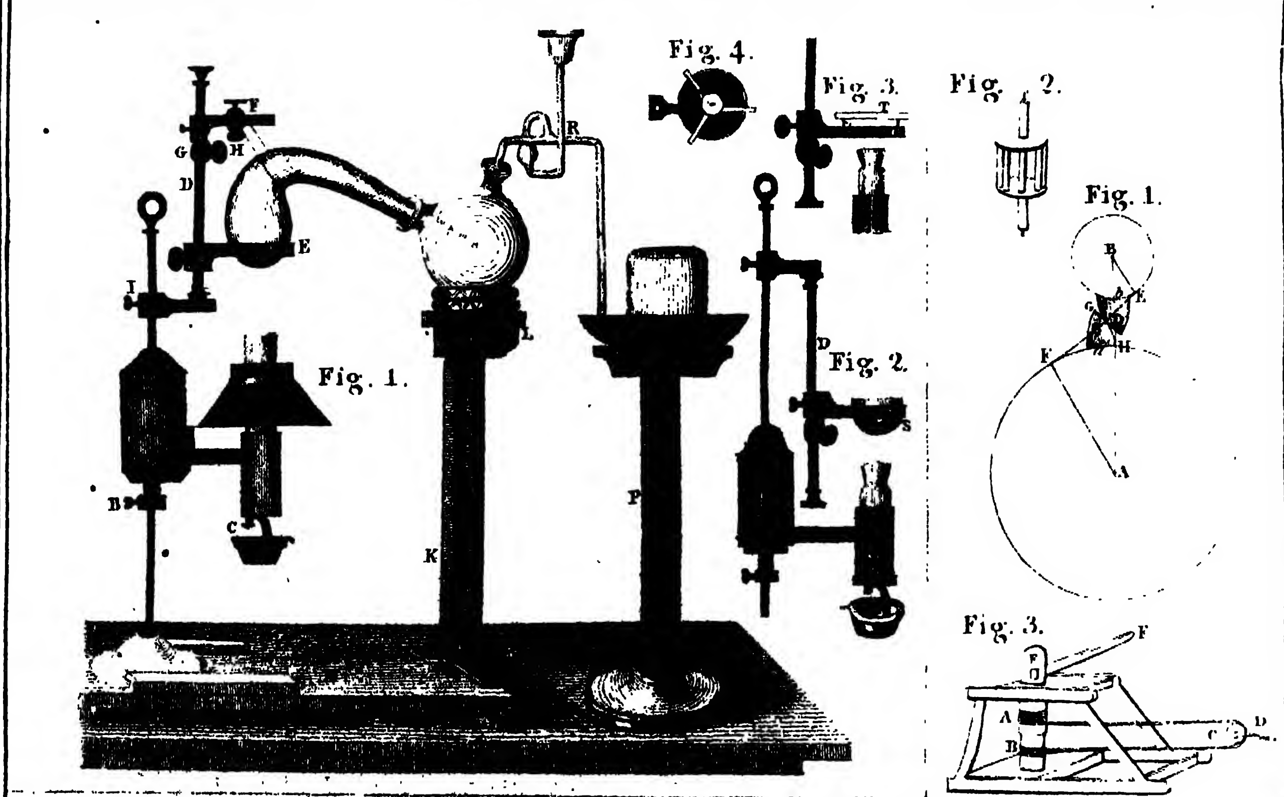
He soon returned to his studies, and in 1771 produced *An Introduction to the History of Great Britain and Ireland*, 4to; a work which he says, "without any of the ordinary incitements to literary labour, he was induced to proceed in by the sole motive of private amusement." The subject of this performance, it might reasonably be supposed, would not excite any violent controversial acrimony; yet neither it nor its author could escape from several most gross and bitter invectives, for some of which he perhaps gave too great occasion.

His next performance produced him neither reputation nor profit. In 1773 he published, *The Iliad of Homer*, translated in two volumes 4to; a work fraught with vanity and self-consequence, and which met with the most mortifying reception from the public. It was condemned by the critics, ridiculed by the wits, and neglected by the world. Some of his friends, and particularly Sir John Elliott, endeavoured to rescue it from contempt, and force it into notice. Their success was not equal to their efforts.

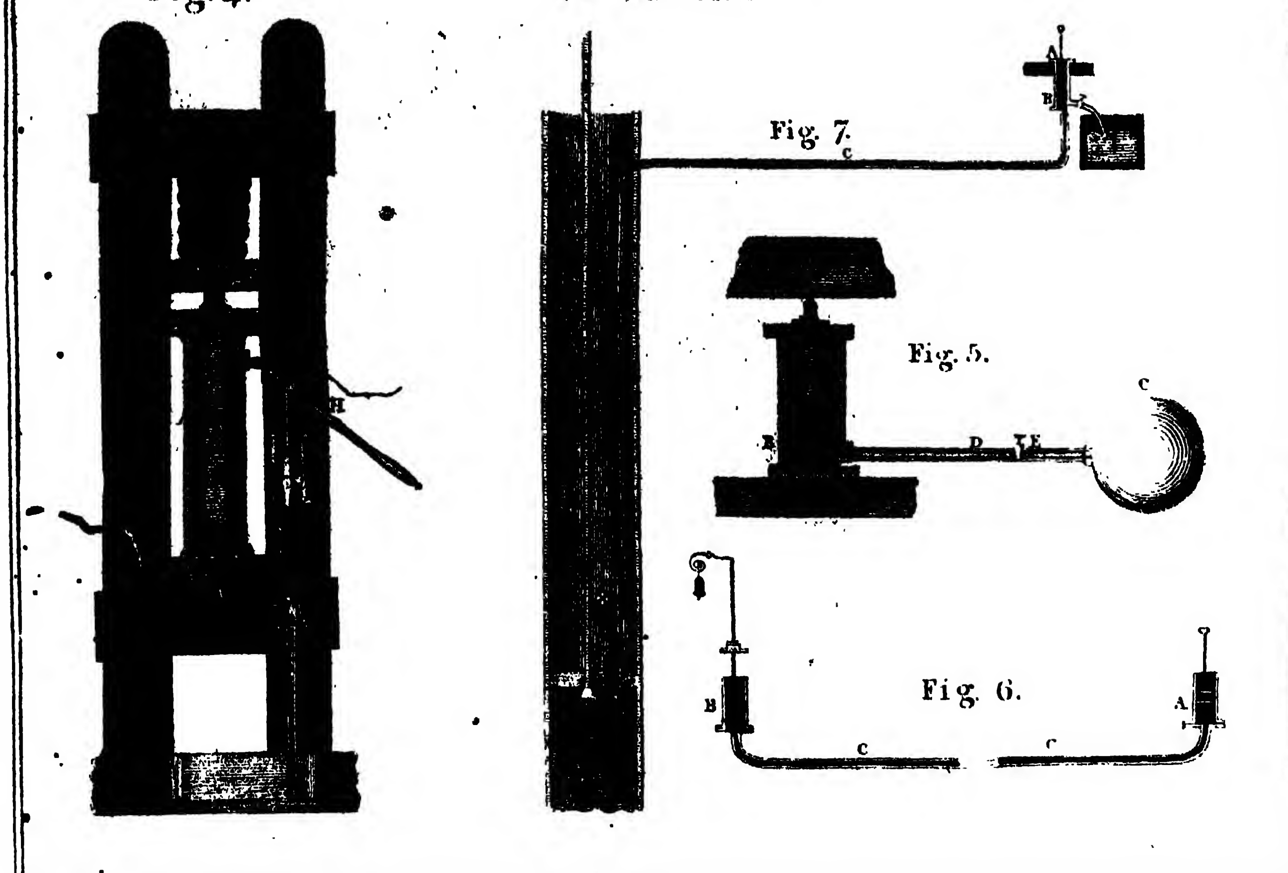
About this time seems to be the period of Mr Macpherson's literary mortifications. In 1773 Dr Johnson and Mr Boswell made their tour to the Hebrides, and in the course of it, the former took some pains to examine into the proofs of the authenticity of Ossian. The result of his inquiries he gave to the public in 1775, in his narrative of the tour; and his opinion was unfavourable. "I believe they (*i. e.* the poems, says he), never existed in any other form than that which we have seen. The editor or author never could shew the original; nor can it be shewn by any other. To revenge reasonable incredulity by refusing evidence, is a degree of insolence with which the world is not yet acquainted; and stubborn audacity is the last refuge of guilt. It would be easy to shew it if he had it. But whence could it be had? It is too long to be remembered, and the language had formerly nothing written. He has doubtless inserted names that circulate in popular stories, and may have translated some wandering ballads, if any can be found; and the names and some of the images being recollected, make an inaccurate auditor imagine that he has formerly heard the whole."

Again, he says, "I have yet supposed no imposture but in the publisher; yet I am far from certainty, that some translations have not been lately made, that may

(A) We have been assured that he had associates: and that for the description of Cuchullin's chariot in particular he was indebted to Mr Macpherson of *Stramasbi*. a man of native genius, and though not possessed of very extensive erudition, well acquainted with Gaelic poetry.



MACHINERY



may now be obtruded as parts of the original work.

"Credulity on the one part is a strong temptation to deceit on the other, especially to deceit of which no personal injury is the consequence, and which flatters the author with his own ingenuity. The Scots have something to plead for their easy reception of an improbable fiction: they are seduced by their fondness for their supposed ancestors. Neither ought the English to be much influenced by Scotch authority; for of the past and present state of the whole Erse nation, the Lowlanders are at least as ignorant as ourselves. To be ignorant is painful; but it is dangerous to quiet our uneasiness by the delusive opiate of hasty persuasion."

These reasonings, if reasonings they can be called, might have been easily answered, had not Macpherson pretended to the possession of at least one manuscript which certainly never existed. He did not, however, attempt to answer them; but adopted a mode of proceeding which tended only to convince the world that Johnson's opinion had some foundation, and that the editor of Ossian had more imagination than sound judgement. Prompted by his evil genius, he sent a menacing letter to his illustrious antagonist, which produced the following brief but spirited reply:

"Mr James Macpherson, No date.

"I received your foolish and impudent letter. Any violence that shall be offered to me, I will do my best to repel; and what I cannot do for myself, the law shall do for me; for I will not be hindered from exposing what I think a cheat, by the menaces of a ruffian. What! Would you have me retract? I thought your work an imposition: I think so still; and, for my opinion, I have given reasons, which I dare you to refute. Your abilities, since your *Homer*, are not so formidable; and what I hear of your morality, inclines me to believe rather what you shall prove than what you shall say."

Whether this letter shewed to Macpherson the imprudence of his conduct, or that he had been made sensible of his folly by the interposition of friends, we know not; but certain it is, we hear no more afterwards of this ridiculous affair, except that our author is supposed to have assisted Mr Macnicol in an answer to Dr Johnson's Tour, printed in 1779. This supposition we are inclined to consider as well founded, because we have been told by a gentleman of veracity, that Mr Macnicol affirms, that the scurrility of his book, which constitutes a great part of it, was inserted, unknown to him, after the manuscript was sent for publication to London.

In 1775 Mr Macpherson published *The History of Great Britain from the Restoration to the Accession of the House of Hanover*, in two volumes 4to; a work in our opinion of great merit, though by one party it has been industriously, and, we are sorry to add, too successfully, decried. As an historian, our author could not indeed boast the attic elegance of a Robertson, the splendour of a Gibbon, or the philosophical profundity of a Hume; but his *style*, though it has sometimes been the avowed, was not the real cause of the coldness with which his history was received. The writer of this sketch once saw a gentleman of rank, and of the Whig interest, turn over one of Macpherson's volumes, and heard him say, upon shutting the book, "I cannot bear that work." He was asked if he thought the narrative false? and he replied, "No! It is too true; but I cannot bear it, because it gives me a bad opinion of those great men to whom I have been accustomed to look back with reverence as to the saviours of my country."

That it has been abhorred by others on the same account, we have not a doubt; and yet language has no name too contemptuous for those who will not follow truth whithersoever she may lead them; or who, on the absurd pretence of having already made up their minds, will not study the evidence on both sides of a disputed question in our national history. A man needs not surely disapprove of the Revolution, or of the subsequent settlements, though he should find complete proofs that Danby and Sunderland were crooked politicians, that Marlborough was ungrateful, or even that King William himself was not that upright and disinterested character which from their infancy they have been taught to believe. It is no uncommon thing for Divine Providence to accomplish good ends by wicked instruments. Every Protestant surely considers the Reformation as one of the most blessed events that have taken place in the world since the first preaching of the gospel of Christ; yet he would be a hardy champion who should undertake to vindicate the motives which influenced the conduct of the first reformers—of Henry VIII. for instance, or even of Luther himself. And why may not the Revolution be considered as in the highest degree beneficial to the country, though the conduct of some of those who brought it about should be found to be such as Macpherson represents it?

That author certainly acted with great fairness; as together with the history he published the proofs upon which his facts were founded, in two quarto volumes, intitled, *Original Papers, containing the secret History of Great Britain, from the Restoration to the Accession of the House of Hanover; to which are prefixed, Extracts from the Life of James II. as written by himself.* These papers were chiefly collected by Mr Carte, but are not all of equal authority. They, however, clear up many obscurities, and set the characters of many persons in past times in a different light from that in which they have been usually viewed. On this account we have no hesitation to say, that he who is capable of sacrificing prejudice to truth, and wishes to understand the politics of the reigns of James, and William, and Anne, should study with care the volumes of Macpherson.

Soon after this period, the tide of fortune flowed very rapidly in Mr Macpherson's favour, and his talents and industry were amply sufficient to avail himself of every favourable circumstance which arose. The resistance of the Colonies called for the aid of a ready writer to combat the arguments of the Americans, and to give force to the reasons which influenced the conduct of government, and he was selected for the purpose. Among other things (of which we should be glad to receive a more particular account), he wrote a pamphlet, which was circulated with much industry, intitled, *The Rights of Great Britain asserted against the Claims of the Colonies; being an Answer to the Declaration of the General Congress*, 8vo, 1776, and of which many editions were published. He also was the author of *A Short History of Opposition during the last Session of Parliament*,

Macpherson. *Parliament*, 8vo, 1779; a pamphlet which, on account of its merit, was by many ascribed to Mr Gibbon.

But a more lucrative employment was conferred on him about this time. He was appointed agent to the nabob of Arcot, and in that capacity exerted his talents in several appeals to the public in behalf of his client. Among others, he published, *Letters from Mahommed Ali Chan, Nabob of Arcot, to the Court of Directors; to which is annexed, a State of Facts relative to Tanjore, with an Appendix of Original Papers*, 4to, 1777; and he was supposed to be the author of *The History and Management of the East India Company from its Origin in* 1600 *to the present Times*, vol. i. containing the affairs of the Carnatic, in which the rights of the nabob are explained, and the injustice of the Company proved, 4to, 1779.

In his capacity of agent to the nabob, it was probably thought requisite that he should have a seat in the British Parliament. He was accordingly in 1780 chosen member for Camelford; but we do not recollect that he ever attempted to speak in the House. He was also rechosen in 1784 and 1790.

He had purchased, we think before the year 1790, an estate in the parish in which he was born; and changing its name from *Retz* to *Belville*, built on it a large and elegant mansion, commanding a very romantic and picturesque view; and thither he retired, when his health began to fail, in expectation of receiving benefit from the change of air. He continued, however, to decline; and after lingering some time, died at his seat at Belville, in Inverness, on the 17th of February 1796.

He appears to have died in very opulent circumstances; and by his will, dated June 1793, gave various annuities and legacies to several persons to a great amount. He also bequeathed L. 1000 to John Mackenzie of Figtree Court, in the Temple, London, to defray the expence of printing and publishing Ossian in the original. He directed L. 300 to be laid out in erecting a monument to his memory in some conspicuous situation at Belville, and ordered that his body should be carried from Scotland, and interred in the Abbey Church of Westminster, the city in which he had passed the best part of his life. His remains were accordingly taken from the place where he died, and buried in the Poets Corner of Westminster church.

Macpherson, Magma.

MAGMA is properly the *refuse* of any substance which has been subjected to pressure; but, in chemistry, the term is sometimes used to denote a mixture of two or more bodies, reduced to the consistence of dough or paste.

MAGNETISM.

IN natural philosophy.—Our intention in the present article was principally to give a more distinct account of the theory of Mr Æpinus than is contained in the article MAGNETISM of the *Encyclopedia Britannica*, referring for proof and illustration to the many facts contained in that article: but, on more mature consideration, we concluded, that this method would fret and confuse the reader by continual references, and leave but a feeble impression at last. We have therefore preferred the putting the whole into the form of a short treatise on magnetism, similar to our supplementary article of ELECTRICITY. This, we hope, will be more perspicuous and satisfactory; still leaving to the reader the full use of all the information contained in the article MAGNETISM of the Dictionary.

1 Reasons why the ancients knew so little of natural philosophy.

The knowledge which the antient naturalists possessed of this subject was extremely imperfect, and affords, we think, the strongest proof of their ignorance of the true method of philosophising; for there can hardly be named any object of physical research that is more curious in itself, or more likely to engage attention, than the apparent life and activity of a piece of rude unorganised matter. This had attracted notice in very early times; for Thales attributed the characteristic phenomenon, the attraction of a piece of iron, to the agency of a mind or soul residing in the magnet. Philosophers, as they were called, seem to have been contented with this lazy notice of a slight suggestion, unbecoming an inquirer, and rather such as might be expected from the most incurious peasant. Even Aristotle, the most zealous and the most systematic student of Nature of whose labours we have any account, has collected no information that is of any importance. We know that the general imperfection of ancient physics has been ascribed to the little importance that was attached to the knowledge of the material world by the philosophers of Greece and Rome, who thought human nature, the active pursuits of men, and the science of public affairs, the only objects deserving their attention. Most of the great philosophers of antiquity were also great actors on the stage of human life, and despised acquisitions which did not tend to accomplish them for this dignified employment: but they have not given this reason themselves, though none was more likely to be uppermost in their mind. Socrates dissuades from the study of material nature, not because it was unworthy of the attention of his pupils, but because it was too difficult, and that certainty was not attainable in it. Nothing can more distinctly prove their ignorance of what is really attainable in science, namely, the knowledge of the *laws of nature*, and their ignorance of the only method of acquiring this knowledge, viz. observation and experiment. They had entertained the hopes of discovering the *causes* of things, and had formed their philosophical language, and their mode of research, in conformity with this hopeless project. Making little advances in the discovery of the causes of the phenomena of material nature, they deserted this study for the study of the conduct of man; not because the discovery of causes was more easy and frequent here, but because the study itself was more immediately interesting, and because any thing like superior knowledge in it puts the possessor in the desirable situation of an adviser, a man of superior wisdom; and as this study was closely connected with morals, because the fear of God is truly the beginning of wisdom, the character of the philosopher acquired an eminence and dignity which was highly flattering to human vanity. Their procedure in the moral and intellectual sciences is strongly marked with the same ignorance of the true method of philo-

philosophising; for we rarely find them forming general propositions on copious inductions of facts in the conduct of men. They always proceed in the synthetic method, as if they were fully conversant in the first principles of human nature, and had nothing to do but to make the application, according to the established forms of logic. While we admire, therefore, the sagacity, the penetration, the candid observation, and the happy illustration, to be found in the works of the ancient moralists and writers on jurisprudence and politics, we cannot but lament that such great men, frequently engaged in public affairs, and therefore having the finest opportunities for deducing general laws, have done so little in this way; and that their writings, however engaging and precious, cannot be considered as any thing more refined than the observations of judicious and worthy men, with all the diffuseness and repetition of ordinary conversation. All this has arisen from the want of a just notion of what is attainable in this department of science, namely, the laws of intellectual and moral nature; and of the only possible method of attaining this knowledge, viz. observation and experiment, and the formation of general laws by the induction of particular facts.

2 Dr Gilbert was the first experimental enquirer about magnetism.

We have been led into these reflections by the inattention of the ancients to the curious phenomena of magnetism; which must have occurred in considerable and entertaining variety to any person who had taken to the experimental method. And we have hazarded these free remarks, expecting the acquiescence of our readers, because the superior knowledge which we, in these later days, have acquired of the magnetical phenomena, were the first fruits of the true method of philosophising. This was pointed out to the learned world in 1590 by our celebrated countryman Chancellor Bacon, in his two great works, the *Novum Organum Scientiarum*, and *De Argumentis Scientiarum*. Dr Gilbert of Colchester, a philosopher of eminence in many respects, but chiefly because he had the same just views of philosophy with his noble countryman, published about the same time his *Physiologia Nova, seu Tractatus de Magnete et Corporibus magneticis*. In the introduction, he recounts all the knowledge of the antients on the subject, and their supine inattention to what was so entirely in their hands; and the impossibility of ever adding to the stock of useful knowledge, so long as men imagined themselves to be philosophising while they were only repeating a few cant words, and the unmeaning phrases of the Aristotelian school. It is curious to remark the almost perfect sameness of Dr Gilbert's sentiments and language with those of Lord Bacon. They both charge, in a peremptory manner, all those who pretend to inform others, to give over their dialectic labours, which are nothing but ringing changes on a few trite truths, and many unfounded conjectures, and immediately to betake themselves to experiment. He has pursued this method on the subject of magnetism with wonderful ardour, and with equal genius and success; for Dr Gilbert was possessed both of great ingenuity, and a mind fitted for general views of things. The work contains a prodigious number and variety of observations and experiments, collected with sagacity from the writings of others, and instituted by himself with considerable expence and labour. It would indeed be a miracle, if all Dr Gilbert's general inferences were just, or all his experiments accurate. It was untrodden ground. But, on the whole, this performance contains more real information than any writing of the age in which he lived, and is scarcely exceeded by any that has appeared since. We may hold it with justice as the first fruits of the Baconian or experimental philosophy.

This work of Dr Gilbert's relates chiefly to the loadstone, and what we call magnets, that is, pieces of steel which have acquired properties similar to those of the loadstone. But he extends the term *magnetism*, and the epithet *magnetic*, to all bodies which are affected by loadstones and magnets in a manner similar to that in which they affect each other. In the course of his investigation, indeed, he finds that these bodies are only such as contain iron in some state or other: and in proving this limitation he mentions a great variety of phenomena which have a considerable resemblance to those which he allows to be magnetical, namely, those which he called *electrical*, because they were produced in the same way that amber is made to attract and repel light bodies. He marks with care the distinctions between these and the characteristic phenomena of magnets. He seems to have known, that all bodies may be rendered electrical, while ferrugineous substances alone can be made magnetical.

It is not saying too much of this work of Dr Gilbert's to affirm, that it contains almost every thing that we know about magnetism. His unwearied diligence in searching every writing on the subject, and in getting information from navigators, and his incessant occupation in experiments, have left very few facts unknown to him. We meet with many things in the writings of posterior inquirers, some of them of high reputation, and of the present day, which are published and received as notable discoveries, but are contained in the rich collection of Dr Gilbert. We by no means ascribe all this to mean plagiarism, although we know traders in experimental knowledge who are not free from this charge. We ascribe it to the general indolence of mankind, who do not like the trouble of consulting originals, where things are mixed with others which they do not want, or treated in a way, and with a painful minuteness, which are no longer in fashion. Dr Gilbert's book, although one of those which does the highest honour to our country, is less known in Britain than on the continent. Indeed we know but of two British editions of it, which are both in Latin; and we have seen five editions published in Germany and Holland before 1628. We earnestly recommend it to the perusal of the curious reader. He will (besides the sound philosophy) find more facts in it than in the two large folios of Scarella.

After this most deserved eulogy on the parent of magnetical philosophy, it is time to enter on the subject.

4 [illegible] the

In mechanical philosophy, a phenomenon is not to be considered as explained, unless we can shew that it is the certain result of the laws of motion applied to matter. It is in this way that the general propositions in physical astronomy, in the theory of machines, in hydraulics, &c. are demonstrated. But the phenomena called *magnetical* have not as yet obtained such an explanation. We do not see their immediate cause, nor can we say with confidence that they are the effects of any

ary particular kind of matter, acting on the bodies either by impulsion or pressure.

All that can be done here is to class the phenomena in the most distinct manner, according to their generality. In this we obtain a two-fold advantage. We may take it for granted that the most general phenomenon is the nearest allied to the general cause. But, farther, we obtain by this method a true theory of all the subordinate phenomena. For a just theory is only the pointing out the general fact of which the phenomenon under consideration is a particular instance. Beginning therefore with the phenomenon which comprehends all the particular cases, we explain those cases in shewing *in what manner* they are included in the general phenomenon, and thus we shall be able to predict what will be the result of putting the body under consideration into any particular situation. And perhaps we may find, in them all, coincidences which will enable us to shew that they are all modifications of a fact still more general. If we gain this point, we shall have established a complete theory of them, having discovered the general fact in which they are all comprehended. Should we for ever remain ignorant of the cause of this general fact, we have nevertheless rendered this a complete branch of mechanical theory. Nay, we may perhaps discover such circumstances of resemblance between this general fact and others, with which we are better acquainted, that we shall, with great probability at least, be able to assign the cause of the general fact itself, by shewing the law of which it is a particular instance.

We shall attempt this method on the present occasion.

5
Leading facts.

The leading facts in magnetism are the two following:

[illegible]

1. If any oblong piece of iron, such as a bar, rod, or wire, be so fitted, that it can assume any direction, it will arrange itself in a certain determinate direction with respect to the axis of the earth. Thus, if, in any part of Britain, an iron or steel wire be thrust through a piece of cork, as represented in fig. 1. so as that the whole may swim level in water, and if it be laid in the water nearly north-west and south-east, it will slowly change its position, and finally settle in a direction, making an angle of about 25 degrees with the meridian.

Plate [illegible]XIV.

This experiment, which we owe to Dr Gilbert (see B. I. ch. 11.), is delicate, and requires attention to many circumstances. The force with which the iron tends toward this final position is extremely weak, and will be balanced by very minute and otherwise insensible resistances; but we have never found it fail when executed as here directed. An iron wire of the size of an ordinary quill, and about eight or ten inches long, is very fit for the purpose. It should be thrust through the cork at right angles to its axis; and so adjusted, by repeated trials, as to swim level or parallel to the horizon. The experiment must also be made at a great distance from all iron; therefore in a bason of some other metal or earthen ware. It may sometimes require a very long while before the motion begin; and if the wire has been placed at right angles to the direction which we have mentioned as final, it will never change its position: therefore we have directed it to be laid in a direction not too remote, yet very sensibly different from the final direction.

But this is not the true position [illegible] iron rod. If it be thrust through a pi[illegible] of wood or cork perfectly spherical, in such a manner that it passes thro' its centre, and if the centre of gravity coincide with this centre, and the whole be of such weight as to remain in any part of the water, without either ascending or descending, then it will finally settle in a plane inclined to the meridian about 25°, and the north end will be depressed about 73 below the horizon.

All this is equivalent with saying, that if any oblong piece of iron or steel be very nicely poised on its centre of gravity, and at perfect liberty to turn round that centre in every direction, it will finally take the position now mentioned.

We have farther to observe with regard to this experiment, that it is indifferent which end of the rod be placed toward the north in the beginning of the experiment. That end will finally settle toward the north; and if the experiment be repeated with the same rod, but with the other end north, it will finally settle in this new attitude. It is, however, not always that we find pieces of iron thus perfectly indifferent. Very frequently one end affects the northerly position, and we cannot make the other end assume its place: the causes of this difference will be clearly seen by and bye.

6
Magnetical position.

The position thus affected by a rod of iron is called by Dr Gilbert the MAGNETICAL POSITION OR DIRECTION. It is not the same, nor parallel, in all parts of the earth, as will be more particularly noticed afterwards.

7
Second fact.
Iron attracts and repels iron.

[illegible] a piece of iron, [illegible] or nearly so, and at [illegible] every direction, is ap-pr[illegible]iece of iron, held nearly in [illegible]y it; that is, the moveable [illegible] to the one that [illegible] at last come into contact with it, and may [illegible] be slowly drawn along by it.

This phenomenon, although not so delicate as the former, is still very nice, because the attraction is so weak that it is balanced by almost insensible obstructions. But the experiment will scarcely fail if conducted as follows: Let a strong iron wire be made to float on water by means of a piece of cork, in the manner already described, having one end under water. See fig. 1. B.

When it is nearly in the magnetical position, bring the end of a pretty big iron rod, such as the point of a new poker, within a quarter of an inch of its southern end (holding the poker in a position not very different from the magnetical position), and hold it there for some time, not exactly southward from it, but a little to one side. The floating iron will be observed to turn towards it with an accelerated motion; will touch it, and may then be drawn by it through the water in any direction. We shall have the same result by approaching the northern extremity of the floating iron with the upper end of the poker.

The same phenomenon may be observed by suspending the first piece of iron by its middle by a long and slender hair or thread. The suspension must be long, otherwise the stiffness of the hair or thread may be sufficient for balancing the very small force with which the pieces of iron tend toward each other. The phenomenon

non may also be observed in a piece of iron which turns freely on a fine point, like the needle of the mariner's compass.

In this, as in the former experiment, the ends of the pieces of iron are observed, in general, to be indifferent; that is, either end of the one will attract either end of the other. It often happens, however, that the ends are not thus indifferent, and that the end of the moveable piece of iron, instead of approaching the other, will be observed to recede from it, and appear to avoid it. We shall soon learn the cause of this difference in the states of iron.

This action mutual. It is scarcely necessary to remark, that we must infer from these experiments, that the action is mutual between the two pieces of iron. Either of them may be the moveable piece which approaches the other, manifesting the attraction of that other. This reciprocity of action will be abundantly verified and explained in its proper place.

9 Not peculiar to magnets or loadstone; These two facts were long thought to be peculiar to loadstones and artificial magnets, that is, pieces of iron which have acquired this property by certain treatment with loadstones; but they were discovered by Dr Gilbert to be inherent in all iron in its metallic state; and were thought by him to be necessary consequences of a general principle in the constitution of this globe. These phenomena are indeed much more conspicuous in loadstones and magnets; and it is therefore with such that experiments are best made for learning their various modifications.

10 ...at, in iron, indifferent, and ...omentary, and in loadstones, is fixed and determinate. But there is another circumstance, besides the degree of vivacity, in which the magnetism of common iron and steel remarkably differs from that of a loadstone or magnet. When a loadstone or magnet is so supported as to be at liberty to take any position, it arranges itself in the magnetical direction, and *one determined end* of it settles in the northern quarter; and if it be placed so that the other end is in that situation, it does not remain there, but gradually turns round, and, after a few oscillations, the *same end* ultimately settles in the north. This is distinctly seen in the needle of the mariner's compass, which is just a small magnet, prepared in the same way with all other magnets. The several ends of loadstones or magnets are thus permanently the north or the south ends; whereas we said that either end of a piece of common iron being turned to the northern quarter, it finally settles there.

It is this circumstance which has rendered magnetism so precious a discovery to mankind, by furnishing us with the compass, an instrument by which we learn the different quarters of the horizon, and which thus tells the direction of a ship's course through the pathless ocean (see COMPASS and VARIATION, *Encycl.*); and also shews us the directions of the veins and workings in the deepest mines. It was natural therefore to call those the north and south ends of the mariner's needle, or of a loadstone or magnet. Dr Gilbert called them the POLES of the loadstone or magnet. He had found it convenient for the proposed train of his experiments to form his loadstones into spheres, which he called TERRELLÆ, from their resemblance to this globe; in which case the north and south ends of his loadstones were the poles of the terrellæ. He therefore gave the name *pole* to that part of any loadstone or magnet which thus turned to the north or south. The denomination was adopted by all subsequent writers, and now makes a term in the language of magnetism.

Also, when we approach either end of a piece of iron A to either end of another B, these ends mutually attract; or if either end of a magnet A be brought near either end of a piece of common iron, they mutually attract each other. But if we bring that end of a magnet A which turns to the north near to the *similar* end of another magnet B, these ends will not attract each other, but, on the contrary, will repel. If the two magnets are made to float on pieces of wood, and have their north poles fronting each other, the magnets will retire from each other; and in doing so, they generally turn round their axes, till the north pole of one front the south pole of the other, and then they run together. This is a very notable distinction between the magnetism of magnets and that of common iron; and whenever we see a piece of iron shew this permanent distinction of its ends, we must consider it as a magnet, and conclude that it has met with some peculiar treatment.

It is not, however, strictly true, that the poles of loadstones or magnets are so fixed in particular parts of their substance, nor that the poles of the same name so constantly repel each other; for if a small or weak magnet A have its pole brought near the similar pole of a large or strong magnet B, they are often found to attract when almost touching, although at more considerable distances they repel each other. But this is not an exception to the general proposition; for when the north pole of A is thus attracted by the north pole of B, it will be found, by other trials, to have all the qualities of a south pole, while thus in the neighbourhood of the north pole of B.

The magnetic properties and phenomena are conveniently distinguished into those of FORCE and of POLARITY. Those of the first class only were known to the ancients, and even of them their knowledge was extremely scanty and imperfect. They may all be classed under the following general propositions.

1. The similar poles of two magnets repel each other with a force decreasing as the distances increase. Similar poles repel and dissimilar ... attract each other.

2. The dissimilar poles of two magnets attract each other with a force decreasing as the distances increase.

3. Magnets arrange themselves in a certain determinate position with respect to each other.

The first object of research in our farther examination of these properties is the relation which is observed to obtain between the distances of the acting poles and their force of action. This has accordingly occupied much attention of the philosophers, and numberless experiments have been made in order to ascertain the law of variation, both of the attraction and the repulsion. A great number of these have been narrated in the article MAGNETISM of the *Encycl.* from which it appears that it has been a matter of great difficulty, and had not been ascertained with certainty or precision when that article was published. It is obvious, from the nature of the thing, that the determination is very difficult, and the investigation very complicated. We can only observe the simultaneous motion of the whole magnet; yet we know that there are four separate actions coexisting and contributing in different directions, and with different forces, to the sensible effect. The force which we measure, in any way whatever, is compounded

pounded of four different forces, which we cannot separate and measure apart; for the north pole of A repels the north pole of B, and attracts its south pole, while the south pole of A exerts the opposite forces on the same poles of B. The attraction which we observe is the excess of two unequal attractions above two unequal repulsions. The same might be said of an observed repulsion. Nay, the matter is incomparably more complicated than this; because, for any thing that we know, *every* particle of A acts on *every* particle of B, and is acted on by it; and the intensity of those actions may be different at the same distances, and is certainly different when the distances are so. Thus there is a combination of an unknown number of actions, each of which is unknown individually, both in direction and intensity. The precise determination is therefore, in all probability, impossible. By precise determination, we mean the law of mutual action between two magnetic particles, or that precise function of the distance which defines the intensity of the force; so that measuring the distance of the acting particles on the axis of a curve, the ordinates of the curve may have the proportions of the attractions and repulsions.

It is almost needless to attempt any deduction of the law of variation from the numerous experiments which have been published by different philosophers. An ample collection of them may be seen in Scarella's treatise. Mr Muschenbroek has made a prodigious number; but all are so anomalous, and exhibit such different laws of diminution by an increase of distance, that we may be certain that the experiments have been injudicious. Attention has not been paid to the proper objects. Magnets of most improper shapes have been employed, and of most diffuse polarity. No notice has been taken of a circumstance which, one should think, ought to have occupied the chief attention; namely, the joint action of four poles, of which the experiment exhibits only the complex result. A very slight reflection might have made the enquirer perceive, that the attractions or repulsions are not the most proper phenomena for declaring the precise law of variation; because what we observe is only the excess of a small difference of attractions and repulsions above another small difference. Mr Hawksbee and Dr Brook Taylor employed a much better method, by observing the deviations from the meridian which a magnet occasioned in a compass needle at different distances. This is occasioned by the difference of the two sums of the same forces; and this difference may be made a hundred times greater than the other. But they employed magnets of most improper shapes.

We must except from this criticism the experiments of Mr Lambert, recorded in the Memoirs of the Academy of Berlin for 1756, published in 1758. This most sagacious philosopher (for he highly merits that name) placed a mariner's needle at various distances from a magnet, in the direction of its axis, and observed the declination from the magnetic meridian produced by the magnet, and the obliquity of the magnet to the axis of the needle. Thus, was the action of the magnet set in opposition and equilibrium with the natural polarity of the needle. But the difficulty was to discover in what proportion each of those forces was changed by their obliquity of action on this little lever. No man excelled Mr Lambert in address in devising methods of mathematical investigation. He observed, that when the obliquity of the magnet to the axis of the needle was 30°, it caused it to decline 15°. When the obliquity was 75°, the distance being the same, it declined 30°. Call the obliquity o, and the declination d, and let f be that function of the angle which is proportionable to the action. Also let p be the natural polarity of the needle, and m the force of the magnet. It is evident that

$$p \times f, 15 = m \times f, 30$$

And $p : m = f, 30 : f, 15$; for the same reason

$$p : m = f, 75 : f, 30$$

Therefore $f, 15 : f\, 30 = f, 30 : f, 75$.

But it is well known that

$$\text{Sine } 15 : \text{Sine } 30 = \text{Sine } 30 : \text{Sine } 75.$$

Hence Mr Lambert was led to conjecture, that the sine was that function of the angle which was proportional to the action of magnetism on a lever. But one experiment was insufficient for determining this point. He made a similar comparison of several other obliquities and declinations with the same distances of the magnet, and also with other distances; and he put it past all dispute, that his conjecture was just.

Had Mr Lambert's experiments terminated here, it must be granted that he has made a notable discovery in the theory of the intimate nature of magnetism. It completely refutes all the theories which pretend to explain the action of a magnet by the impulsion of a stream of fluid, or by pressure arising from the motion of such a stream; for in this case the pressure on the needle must have diminished in the duplicate ratio of the sine. The directive power with the angle 90 must be 4 times greater than with the angle 30°; whereas it was observed to be only twice as great. Magnetism does not act therefore by the impulsion or pressure of a stream of fluid, but in the manner of a simple incitement, as we conceive attraction or repulsion to act.

Having ascertained the effect of obliquity, Mr Lambert proceeded to examine the effect of distance; and, by a most ingenious analysis of his observations, he discovered, that if we represent the force of the magnet by f, and the distance of the nearest pole of the magnet from the centre of the needle by z, and if a be a constant quantity, nearly equal to two-thirds of the length of the needle, we have f proportional to $\overline{z-a}^2$.

Mr Lambert found this hold with very great exactness with magnets ten times larger, and needles twice as short. But he acknowledges, that it gives a very singular result, as if the action of a magnet were exerted from a centre beyond itself. He attributes this to its true cause, the still great complication of the result, arising from the action of the remote pole of the magnet. He therefore takes another method of examination, which we shall understand by and bye, when we consider the *directive* power of a magnet. (We have mentioned this imperfect attempt chiefly on account of the unquestionable manner in which he has ascertained the effect of obliquity, and the importance of this determination.

We have attempted this investigation in a very simple manner. We got some magnets made, consisting of two balls connected by a slender rod. By a very particular mode of impregnation, we gave them a pretty good magne-

magnetism; and the force of each pole seemed to reside almost in the centre of the ball. This was our object in giving them this shape. It reduced the examination both of the attractive and of the directive power to a very easy computation. The result was, that the force of each pole varied in the inverse duplicate ratio of the distance. The error of this hypothesis in no case amounted to $\frac{1}{1}$th of the whole. In computing for the phenomena of the directive power, the irregularities and deviations from this ratio were much smaller.

The previous knowledge of this function would greatly expedite and facilitate our farther investigation: but we must content ourselves with a very imperfect approximation, and with arriving at the desired determination by degrees, and by a very circuitous route.

16 mpt plain pheno- a with- a pre- know- e of law.

It is a matter of experience, that when two magnets are taken, each of which is as nearly equal as possible in the strength of both poles, then, if they are placed with their axes in one straight line, and the north pole of one fronting the south pole of the other, they attract each other with a force which diminishes as the distance increases; and this variation of force is regular, that is, without any sudden changes of intensity, till it becomes insensible. No instance has occurred of its breaking suddenly off when of any sensible force; but it appears to diminish continually like gravity. No instance occurs in which attraction is changed into repulsion.

But it is, moreover, to be particularly remarked, that, having made this observation with the north pole of A fronting the south pole of B, if the experiment be repeated with the south pole of A fronting the north pole of B, the results will be precisely the same. And, lastly, it is a matter of unexcepted experience, that the sensible action of A on B, measured by the force which is necessary for preventing the farther approach of B, is precisely equal to the action of B on A. This is the case, however unequal the force of the two magnets may be; that is, although A may support ten pounds of iron, and B only ten ounces.

Now, the simplest view we can take of this experiment is, by supposing the whole action of one end or pole of a magnet to be exerted at one point of it. This will give us four actions of A on B, accompanied by as many equal and opposite actions of B on A. It is plain that we may content ourselves with the investigation of one only of these sets of actions.

What we observe is the excess of the attractions of the poles of A for the dissimilar poles of B above the repulsions of the same poles of A for the similar poles of B. At all distances there is such an excess. The sum of the attractions exceeds the sum of the repulsions competent to every distance.

Now this will really happen, if we suppose that the poles of a magnet are of equal strength, and that, however these different magnets differ in strength, they have the same law of diminution by an increase of distance. The first circumstance is a very possible thing, and the last is demonstrated by the observed equality of action and reaction. Every thing will now appear very plain, by representing (as we did in ELECTRICITY, *Suppl.* nº 44, &c.) the intensities of attraction and repulsion by the ordinates of a curve, of which the abscissæ represent the distances of the acting poles.

Therefore let A and B (fig. 2.) represent the two magnets, placed with their four poles S, N, *s*, *n*, in a straight line. In the straight line O *q* take O *m*, O *p*, O *n*, O *q*, respectively equal to N *s*, N *n*, S *s*, S *n*; and let MPNQ be a curve line, having O *q* for its axis and assymptote; and let the curve, in every part, be convex towards its axis. Then draw the ordinates *m* M, *p* P, *n* N, *q* Q, to the curve. These ordinates will represent the intensities of the forces exerted between the poles of the magnets, in such a manner as to fulfil all the conditions that are really observed: For *m* M represents the attraction of the north pole N of the magnet, A for the south pole *s* of the magnet B; *p* P represents the repulsion of N for *n*; *n* N represents the repulsion of S for *s*; and *q* Q represents the attraction of S for *n*. The distance between *m* and *n*, or between *p* and *q*, is equal to the length of the magnet A, and *m p*, or *n q*, is equal to that of B. M *m*, P *p*, and N *n*, Q *q*, are pairs of equidistant ordinates. It surely requires only the inspection of the figure to see that, in whatever situation along the axis we place those pairs of equidistant ordinates, the sum of M *m* and Q *q* will always exceed the sum of P *p* and N *n*; that is, the sum of the attractions will always exceed that of the repulsions. This will not be the case if the curve, whose ordinates are proportional to the forces, have a point Z of contrary flexure, as is represented by the dotted curve PZQ. For this curve, having O *q* for its assymptote (in order to correspond with forces which diminish continually by an increase of distance, but do not abruptly cease) must have its convexity turned toward this assymptote in the remote parts. But there will be an arch MPZ between Z and O, which is concave toward the assymptote. In which case, it is possible that M *m* + Q *q* shall be less than P *p* + N *n*; and then the repulsions will exceed the attractions; which is contrary to the whole train of observation.

It may be thought, that if the repulsion exerted between two particles be always less than the attraction at the same distance, the phenomena will be accounted for, although the law of action be not represented by such a curve as has been assumed. Undoubtedly they will, while the dissimilar poles front each other. But the results of such a supposition will not agree with the phenomena while the similar poles front each other: For it is an uncontradicted fact, that when two fine hard magnets, whose poles are nearly or exactly of equal vigour, have their similar poles fronting each other, the repulsions fall very little short of the attractions at the same distances when their position is changed. When the distances are considerable, scarcely any difference can be observed in the beginning of the experiment. The differences, also, which are observed at smaller distances, are observed to augment by continuing the magnets in their places without changing their distances; and therefore seem to arise from some change produced by each on the magnetism of the other. And, accordingly, if we invert one of the magnets, we shall find that the attractions have been diminished as much as the repulsions. Now, the consequences of magnetic repulsion, being always weaker than attraction, would be the reverse of this. The differences would appear most remarkable in the greater distances, and magnets might be found which repel at small distances, and attract at greater distances; which is contrary to all observation.

From all this it follows, with sufficient evidence for our

our preſent purpoſe, that the function of the diſtance which expreſſes the law of magnetic action muſt be repreſented by the ordinates of a curve of the hyperbolic kind, referred to its aſſymptote as an axis; and therefore always convex toward this axis. We think it alſo ſufficiently clear, that the conſequences which we have deduced from the ſimple ſuppoſition of four acting points; inſtead of the combined action of every particle, may be adopted with ſafety. For they would be juſt, if there were only thoſe four particles; they would be juſt with reſpect to another four particles—therefore they would be juſt when theſe are joined; and ſo on of any number. Therefore the curve, whoſe ordinates expreſs the mean action of each pole, as if exerted by its centre of effort, will have the ſame general form: It will be convex toward its aſſymptotic axis.

It will greatly aid our conceptions of the combined actions of the four magnetic poles, if we notice ſome of the primary properties of a curve of this kind, limited by no other condition.

17 Unqueſtionable inferences from the phenomena.

Draw the chords MQ, PN, MP, NQ. Biſect them in B, D, E, F, and join EF. Draw the ordinates E e F f, and BD b (cutting EF in C). Draw P u parallel to the axis, cutting E e in r. Draw alſo Q i parallel to the axis, cutting F f in e. Alſo draw FHL parallel to the axis, and P o t parallel to QN; and draw PL l, and P e x, cutting M m in l and x.

Let each ordinate be repreſented by the letter at its interſection with the axis. Thus, the ordinates M m and Q q may be repreſented by m and q, &c.

Becauſe MP is biſected in E, M t is double of E r. M l is double of EL; M x is double of E e. Alſo, becauſe P t is parallel to QN, and P u to Q i, we have $t\,u =$ N i. From theſe premiſes, it is eaſy to perceive, that,

1. $B\,b = \dfrac{m+q}{2}$.
2. $D\,b = \dfrac{p+n}{2}$.
3. $BD = \dfrac{\overline{m+q}-\overline{p+n}}{2}$.
4. $M\,u = m-p$.
5. $u\,t = n-q$.
6. $M\,t = \overline{m-p}-\overline{n-q}$.
7. $E\,e = \dfrac{m+p}{2}$.
8. $F\,f = \dfrac{n+q}{2}$.
9. $M\,l = \overline{m+p}-\overline{n+q}$.
10. $EL = \dfrac{\overline{m+p}-\overline{n+q}}{2}$.
11. $CD = \dfrac{\overline{m+q}-\overline{p+n}}{4}$.
12. $CH = \dfrac{\overline{m+p}-\overline{n+q}}{4}$.

Theſe combinations will ſuggeſt to the attentive reader the explanation of many modifications of the combined action of the four poles of two magnets. They are all comprehended in one propoſition, which it will be convenient to render familiar to the thought; namely, if two pairs of equidiſtant ordinates be taken, the ſum of the two extremes exceeds that of the intermediate ones. $m+q$ is greater than $p+n$. Alſo, the difference between the pair neareſt to O exceeds the difference between the remote pair.

Now, conceiving theſe ordinates to repreſent the mutual actions of the magnetic poles, we ſee that their tendency to or from each other, or their ſenſible attractions or repulſions, are expreſſed by $\overline{m+q}-\overline{n+p}$; that is, by the exceſs of the ſum of the actions of the neareſt and moſt remote poles above the ſum of the actions of the intermediate diſtant poles. It will alſo be frequently convenient to conſider this tendency as repreſented by $\overline{m-p}-\overline{n-q}$; that is, by the exceſs of the difference of the actions of the neareſt pole of A on the two poles of B, above the difference of the actions of its remote pole on the ſame poles of B.

Let us now conſider ſome of the chief modifications of theſe actions.

1. Let the diſſimilar poles front each other. It is plain that $m+q$ repreſent attractions, and that $p+n$ repreſent repulſions. Alſo $m+q$ is greater than $p+n$. Therefore the magnets will attract each other. This attraction is alſo repreſented by $\overline{m-p}-\overline{n-q}$. 18 Explanation of the obſerved attraction of magnets,

Now $\overline{m+q}-\overline{p+n}$ is evidently equal to M t, or to twice E r, or to twice BD, or to four times CD.

This action will be increaſed,

1. By increaſing the ſtrength of either of the magnets. The action of the magnets is the combined action of each acting particle of the one on each acting particle of the other; and it is mutual. Therefore all the ordinates will increaſe in the ratio of the ſtrength of each magnet, and their ſums and differences will increaſe in the ſame ratio.

2. By diminiſhing the diſtance between the magnets. For this brings all the ordinates nearer to D, while their diſtances $m\,p$, $p\,n$, $n\,q$, remain as before. In this caſe it is plain, that M u, the difference of M m and P p, will increaſe faſter than $t\,u$ or N i, the difference between N n and Q q. Therefore M t will increaſe; that is, the attraction will increaſe.

3. By increaſing the length of A, while the diſtance between them remains the ſame. For O m remaining the ſame, as alſo $m\,p$ and $n\,q$, while $n\,q$ is only removed farther from $m\,p$; it is plain M u remains the ſame, and that N i and $t\,u$ are diminiſhed; therefore M t muſt increaſe, or the attraction muſt increaſe.

4. By increaſing the length of B, the diſtance between them remaining the ſame. For this increaſes $m\,p$ and $n\,q$; and conſequently increaſes M u and $t\,u$. But M u increaſes more than $t\,u$; and therefore M t is increaſed, and the attraction or tendency is increaſed.

All theſe conſequences of our original ſuppoſition, that the magnetic action may be repreſented by the ordinates of a curve every where convex to an aſſymptotic axis, are ſtrictly conformable to obſervation.

If we place the magnets with their ſimilar poles fronting each other, it is evident that the ordinates which expreſſed attractions in the former caſe, will now expreſs repulſions; and that the forces with which the magnets now repel each other, are equal to thoſe with which they attracted when at the ſame diſtances. When the experiments are made with good loadſtones, or very fine magnets, tempered extremely hard, and having the energy of their poles ſenſibly reſiding in a ſmall ſpace very near the extremities, the reſults are alſo very nearly 19 And their repulſions.

ly conformable to this mathematical theory; but there is generally a weaker action. The magnets seldom repel as strongly as they attract at the same distance; at least when these distances are small. If one or both of the magnets is soft, or if one of them be much more vigorous than the other, there are observed much greater deviations from this theory. The repulsions are considerably weaker than the attractions at the same distance, and the law of variation becomes extremely different. When placed at very considerable distances, they repel. As the magnet B is brought nearer to A, the repulsion increases, agreeably to the theory, but not so fast. Bringing them still nearer, the repulsion ceases to increase, then gradually diminishes, and frequently vanishes altogether, before the magnets are in contact; and when brought still nearer, it is changed into attraction.

22 ...ung ...prions ...ated. But more careful observation shews, that this anomaly does not invalidate the theory. It is found that the vigour of the magnets is permanently changed by this process. The magnets act on each other in such a way as to weaken each other's magnetism. Nay, it frequently happens, that the weaker or the softer of the two has had its magnetism changed, and that the pole nearest to the other has changed its nature. While they are lying in contact, or at such a distance that they attract, although their similar poles front each other, it is found that the pole of one of them is really changed; although it may sometimes recover its former species again, but never so vigorously as when the other magnet is removed. In short, it is observed, that the magnetism is diminished in all experiments in which the magnets repel each other, and that it is improved in all experiments in which they attract.

We have hitherto supposed the magnets placed with their axes in one straight line. If they are differently placed, we cannot ascertain, by this single circumstance of the law of magnetic action, whether they will attract or repel — we must know somewhat more of the variation of force by a change of distance.

...t ...ctive ...it exerted. If the magnet B be not at liberty to approach toward A, or recede from it, but be so supported at its centre B that it can turn round it, it is very plain that it will retain the position in which it is drawn in the figure. For its south pole s being more attracted by N than it is repelled by S, is, on the whole, attracted by the magnet A; and, by this attraction, it would vibrate like a pendulum that is supported at the centre B. In like manner, its north pole n is more repelled by N than it is attracted by S, and is, on the whole, repelled. The part Bn would therefore also vibrate like a pendulum round B. Thus each half of it is urged into the very position which it now has; and if this position be deranged a little, the attraction of sB toward A, and the repulsion of nB from it, would impel it toward the position sBn.

This will be very evident, if we put the magnet B into the position s'Bn', at right angles to the line AB. The pole s' and the pole n' are urged in opposite, and therefore conspiring, directions with equal forces, very nearly at right angles to $n's$, if the magnet B be small. In any oblique position, the forces will be somewhat unequal, and account must be had of the obliquity of the action, in order to know the precise rotative momentum of the actions.

Dr Gilbert has given to this modification of the action of A on B, the name of VIS DISPONENS; which we may translate by DIRECTIVE POWER OF FORCE. Also, that modification of the tendency of B to or from A is called by him the VERTICITAS of B. We might call it the VERTICITY of B; but we think that the name POLARITY is sufficiently expressive of the phenomenon; and as it has come into general use, we shall abide by it.

It is not so easy to give a general, and at the same time precise, measure of the directive power of A and polarity of B. The magnet B must be considered as a lever; and then the force tending to bring it into its ultimate position ns depends both on the distance of its poles from N and S, and also on the angle which the axis of B makes with the line AB. When the axis of B coincides with AB, the force acting on its poles, tending to keep them in that situation, is evidently $\overline{m+p-n+q}$, and therefore may be represented by Ml (in fig. 2.), or by twice EL, or by four times CH. If B has the position n'Bs', perpendicular to AB, let the ordinates Ee and Ff cut the curve on I and K; and draw KL parallel to the axis (our figure causes this line almost to coincide with QL, and in all important cases it will be nearly the same). In this case IL will express one half of this force. Either of these estimations of this modification of the mutual action of the magnets, will be sufficient for the objects we have in view. 22 Its measure.

The directive power of A, and the polarity of B, are increased, 23 How increased and diminished.

1. By increasing the strength of one or both of the magnets. This is evident,

2. By diminishing the distance of the magnets. For this, by increasing the sum of Mm and Pp more than the sum of Nn and Qq, must increase EL or Ml.

3. By increasing the length of A. For this, by removing n and q farther from m and p, must depress the points L and l, and increase EL, or IL, or Ml.

4. By diminishing the length of B, while the distance Ns between the magnets remains the same. For this, by bringing p and q nearer to m and n, must increase Mm + Pp more than Nn + Qq. Or, by bringing Ee and Ff nearer to Mm and Nn, it must increase EL and Ml.

If the distance Ns between the pole of A and the remote pole of B remain the same, the directive force of A, and polarity of B, are diminished by diminishing the length of B, as is easily seen from what has been just now said. It is also diminished, but in a very small degree, by diminishing the length of B, when the distance between the centres of A and B remain the same. For, in this case, the ordinates Ie and Kf retain their places; but the points m and p approach to e; and this brings the intersection E of the ordinate and chord nearer to I, and diminishes EL, because the point L is not so much depressed by the approach of F to K as E is depressed.

But in all cases, the *ratio* of the directive power of A to its attractive force, or of the polarity of B to its tendency to A, is increased by diminishing the length of B. For it is plain, that by diminishing mp and nq, while Ie and Kf keep their places, the point o is raised, the point L is depressed; and therefore the ratio of EL to Eo, or of Ml to Mt, is increased. We even see that, by diminishing the length of B continually Circumstances ...

and

and without end, the ratio of Ml to Mt may be made to exceed any ratio that can be aſſigned.

25
The polarity of a ſmall magnet may be great while the attraction is inſenſible.

Now, ſince diminiſhing the length of B increaſes the ratio of the directive power of A to its attractive power, while increaſing the length of A increaſes both, and alſo increaſes the ratio of EL to Eo (as is very eaſily ſeen), and ſince this increaſe may be as great as we pleaſe, it neceſſarily follows, that if the ſame very ſmall magnet B be placed at ſuch diſtances from a large and ſtrong magnet A, and from a ſmaller and leſs vigorous one C, as to have equal polarities to both, its tendency to A will be leſs than its tendency to C. It may even be leſs in any ratio we pleaſe, by ſufficiently diminiſhing the length of B.

Dr Gilbert obſerved this; and he expreſſes his obſervation by ſaying, that the directive power extends to greater diſtances than the attracting power. We muſt juſt conclude, that the laſt becomes *inſenſible* at ſmaller diſtances than the firſt. This will be found a very important obſervation. It may be of uſe to keep in mind, that the directive power of a magnet A on another magnet B, is the difference of the *ſums* of the actions of each pole of A on both poles of B; and the attractive power of A for another magnet B, is the difference of the *differences* of theſe actions.

It may be alſo remarked juſt now, that the directive force of A always exceeds its attractive force by the quantity $2\ (p-q)$. For their difference may be expreſſed by tl, which is equal to twice oL. Now ot is equal to Pp, or to p; and oL is equal to Pp — Ff, or to Pp—Qq —Ft, or to Pp—Qq—$o t$. Therefore $o\text{L} = \text{P}p - \text{Q}q$, and $tl = 2\ (\text{P}p - \text{Q}q)$, $= 2\ (p-q)$.

By inſpecting this figure with attention, we obtain indications of many intereſting particulars. If the lengths of the magnets A and B are the ſame, the point n in the axis of the curve will coincide with p. As the length of A increaſes, the part nq is removed farther from the part mp. The line Pt becomes leſs inclined to the axis, and is ultimately parallel to it, when o is infinitely remote. At this time L falls on e; ſo that the ultimate ratio of the attraction to the polarity is that of Ee to Ee, when the magnet A is infinitely long. It is then the ratio of the difference of the actions of the neareſt pole of A on the two poles of B to the ſum of theſe actions. Hence it follows, that when A is very great and B very ſmall, the polarity of B is vaſtly greater than its tendency to A. It may have a great polarity when its tendency is inſenſible.

The ratio of the polarity to the attraction alſo increaſes by increaſing the diſtance of the magnets while their dimenſions continue the ſame. This will appear, by remarking that the chords MP and NQ muſt interſect in ſome point w; and that when the four points m, p, n, and q, move off from O, keeping the ſame diſtances from each other, Eo will diminiſh faſter than EL, and the ratio of EL to EO will continually increaſe.

Therefore when a ſmall magnet B is placed at ſuch a diſtance from a great magnet A, and from a ſmaller one C, as to have equal polarity to both, its tendency to C will exceed its tendency to A. For the polarities being equal, it muſt be farther from the great magnet; in which caſe the ratio of its polarity to its attraction is increaſed.

And this will alſo obtain if the magnets differ alſo in ſtrength. For, to have equal polarities, B muſt be ſtill farther from the great and powerful magnet.

For all theſe reaſons, a large and powerful magnet may exert a ſtrong directive power, while its attractive power is inſenſible.

26
Peculiarities of oblique poſitions of two magnets.

We have hitherto ſuppoſed the magnet B to be placed in the direction of the axis of A, and only at liberty to turn round its centre B. But let its centre be placed on the centre of A, as in fig. 3. it muſt evidently take a poſition which may be called ſubcontrary to that of A, the north pole of B turning toward the ſouth pole of A, and its ſouth pole turning toward the north pole of A.

The ſame thing muſt happen when the centre of B is placed in B, any where in the line AE perpendicular to NS. S attracts n with a force nb, while N repels n with a force nc, ſomewhat ſmaller than nb. Theſe two compoſe the force nd. In like manner, the two forces se and sf, exerted by N and S on the pole s, compoſe the force sq. Now if the axis of the magnet B be parallel to NS, but the poles in a contrary poſition, and if each magnet be equally vigorous in both poles, the magnet B will retain this poſition; becauſe the forces nb and se are equal, as alſo the forces nc and sf. Theſe muſt compoſe two forces nd and sq, which are equal, and equally inclined to ns; and they will therefore be in equilibrio on this lever.

Let us now place the centre of the ſmall magnet in C, neither in the axis of the other, nor in the perpendicular AE. Let its north pole n point toward the centre of A. It cannot remain in this poſition; for N repels n with a force nc, while S attracts it with a force nb (ſmaller than nc, becauſe the diſtance is greater). Theſe two compoſe a force nd conſiderably different from the direction sn of its axis. In like manner, the ſouth pole s of the ſmall magnet is acted on by two forces se and sf, exerted by the two poles of A, which compoſe a force sq nearly equal and parallel to nd, but in a nearly oppoſite direction. It is plain that theſe forces muſt turn the ſmall magnet round its centre C, and that it cannot reſt but in a poſition nearly parallel to nd or sf. Its poſition is better repreſented by fig. 4. with its ſouth pole turned toward the north pole of the other magnet, and its north pole in the oppoſite direction.

What the preciſe poſition will be, depends on that function of the diſtance which is always proportional to the intenſity of the action; on the force of each of the poles of A, and on the length of the magnet B. Nay, even when we know this function, the problem is ſtill very intricate.

27
Means of acquiring a near meaſure of the law of action.

There are methods by which we may approximate to the function with ſucceſs. If the magnet B be indefinitely ſmall, ſo that we may conſider the actions on its two poles as equal, the inveſtigation is greatly ſimplified. For, in this caſe, each pole of the ſmall magnet B (fig. 5.) may be conceived as coinciding with its centre. Then, drawing NB, SB, and taking Bb toward N, to repreſent the force with which N attracts the ſouth pole of B, and taking Bc, in SB produced, to repreſent the force with which S repels the ſame pole, the compound force acting on this pole is Bd; the diagonal of a parallelogram Bb, dc. In like manner, we muſt take Be, in Nb produced, and equal to Bb,

to

to represent the repulsion of N for the north pole of B, and B f equal to B c, to represent the attraction of S for this pole. The compound force will be B g, equal and opposite to B d. It follows evidently from this investigation, that the small magnet will not rest in any position but $d g$. In this supposition, therefore, of extreme minuteness of the magnet B, one of the parallelograms is sufficient. We may farther remark, that we have this approximation secure against any error arising from the supposition that all the action of each pole of B is exerted by one point. Although we suppose it diffused over a considerable portion of the magnet, still the extreme minuteness of the whole makes the action, even on its extreme points, very nearly equal.

28 Hence may be derived a construction for ascertaining the position of the needle, when the function m of the distance is given, or for discovering this function by observation of the position of the needle.

Let NS (fig. 5. n° 2.) meet the direction of the needle in K. Make BG = BN, and draw NF, GE, SH, perpendicular to BK. It is evident that B b is to B c, or b d, as the sine of the angle HBS to the sine of KBN. Therefore, because BG and BN are equal, we have B b : B c = GE : NF.

Therefore GE : NF = BS^m : BN^m

But SH : GE = BS : BN

Therefore SH : NF = BS^{m+1} : BN^{m+1}

And SK : NK = BS^{m+1} : BN^{m+1}

If magnetic action be inversely as the distance, we have SK : NK = BS^2 : BN^2, and B is in the circumference of a circle which passes through S and N, and has BK for a tangent, as is plain by elementary geometry. If the action be inversely as the square of the distance, we have SK : NK = BS^3 : BN^3, and B is in the circumference of a curve of more difficult investigation. But, as in the circle, the sum of the angles BSN and BNS is a constant angle, so, in this curve, the sum of the cosines of those angles is a constant quantity. This suggests a very simple construction of the curve. Let it pass through the point T of the line AT, drawn from the centre of the magnet, perpendicular to its axis. Describe the semicircle SPQN, cutting ST and NT in P and Q. Then, in order to find the point where any line SB cuts the curve, let it cut the semicircle in p, and apply the line N q = SP + NQ — S p, and produce it till it meet the line SB in B, which is a point in the curve; for it is evident that S p and N q are the cosines of BSN and BNS. We hope to give, by the help of a learned friend, the complete construction of curves for every value of m, in an Appendix to this article. It will form a new and curious class, arranged by the functions of the angles at N and S.

But, in the mean time, we have determined the position of an indefinitely small needle, in respect of a magnet of which we may conceive the polar activity concentrated in two points; and we may, on the other hand, make use of the observed positions of such a needle and magnet for discovering the value of m. For, since $\frac{SK}{NK}=\frac{SB^{m+1}}{NB^{m+1}}$, it is plain that $m=\frac{\text{Log. SK : NK}}{\text{Log. SB : NB}}-1$. Thus, in an observation which the writer of this article made on a very small needle, and a magnet having globular poles, and $8\frac{1}{3}$ inches between their centres, he found SB = $5\frac{1}{3}$, NB = $\frac{1}{4}$, SK = 11,49, and NK = 3,37. This gives m = 1,97, which differs from 2 only $\frac{1}{33}$th part. Finding it so very near the inverse duplicate ratio of the distance, a circle VUZ was described, the circumference of which is the locus of SB : BN = 8 : 5,333. When the centre of the needle was placed anywhere in the circumference of this circle, it scarcely deviated from the point K, except when so far removed from the magnet that its natural polarity prevailed over the directive power of the magnet, or so near its middle that the action of the cylindrical part became very sensible.

It is plain that the length of the needle must occasion some deviation from the magnetic direction, by destroying the perfect equality of action on its two poles. He therefore employed three needles of $\frac{1}{4}$, $\frac{1}{7}$, and $\frac{1}{2}$ of an inch in length; and by noticing the differences of direction, he inferred what would be the direction, if the forces on each pole were precisely equal. He had the pleasure of seeing that the deviation from the inverse duplicate ratio of the distances was scarcely perceptible.

Mr Lambert's experiments on the directive power of the magnet, narrated in his second dissertation in the 22d volume of the Memoirs of the Academy of Berlin, are the most valuable of all that are on record; and the ingenious address with which they are conducted, and the inferences are drawn, would have done credit to Newton himself. We earnestly recommend the careful perusal of that Essay, as the most instructive of any that we have read. The writer of this found himself obliged to repeat all his former experiments, mentioned above, in Mr Lambert's manner, and with his precaution of keeping the needle in its natural position; a circumstance to which he had not sufficiently attended before. The new results were still more conformable to his conjecture as to the law of variation. Mr Lambert closes his dissertation with an hypothesis, "that the force of each transverse element of a magnet is as its distance from the centre, and its action on a particle of another magnet is inversely as the square of the distance." On this supposition, he calculates the position of a very small needle, and draws three of the curves to which it should be the tangent. These are very exactly coincident with some that he observed. We tried this with several magnetic bars, and found it very conformable to observation in some magnets; but deviating so far in the case of other magnets, that we are convinced that there is no rule for the force of each transverse element of a magnet, and that the magnetism is differently disposed in different magnets. It was chiefly this which induced us to form the magnets employed in this research of two balls united by a slender rod. Lichtenberg, in his notes on Erxleben's Natural Philosophy, says, that there is a MS. of the celebrated Tobias Mayer in the library of the Academy of Gottingen, in which he assumes the hypothesis above-mentioned, and gives a construction of the magnetic curves founded on it, making them a kind of catenaria. The interior curves do indeed resemble the catenaria, but the exterior are totally unlike. But there is no occasion for much argument to convince us, that the first part of this hypothesis is not only gratuitous, but unwarranted by any general phenomena. We know that a magnetical bar may have its magnetism very differently disposed; for it may have more than two poles, and the intermediate poles *cannot* have this disposition of the magnetism.

netism. Such a disposition is perhaps possible; but is by no means general, or even frequent. We are disposed to think, that permanent magnetism must have its intensity diminishing in the very extremity of the bar. The reader may guess at our reasons from what is said in ELECTRICITY, *Suppl.* n° 222.

The following very curious and instructive phenomenon was the first thing which greatly excited the curiosity of the writer of this article, and long puzzled him to explain it. Indeed it was his endeavours to explain it which gradually opened up to him the theory of the mutual action of magnets contained in these paragraphs, and first gave him occasion to admire the sagacity of Dr Gilbert, and to see the connecting principle of the vast variety of observations and experiments which that philosopher had made. It seems owing to the want of this connecting principle, that a book so rich in facts should be so little read, and that so many of Dr Gilbert's observations have been published by others as new discoveries.

Amusing himself in the summer 1758 with magnetic experiments, two large and strong magnets A and B (fig. 6), were placed with their dissimilar poles fronting each other, and about three inches apart. A small needle, supported on a point, was placed between them at D, and it arranged itself in the same manner as the great magnets. Happening to set it off to a good distance on the table, as at F, he was surprised to see it immediately turn round on its pivot, and arrange itself nearly in the opposite direction. Bringing it back to D restored it to its former position. Carrying it gradually out along DF, perpendicular to NS, he observed it to become sensibly more feeble, vibrating more slowly; and when in a certain point E, it had no polarity whatever towards A and B, but retained any position that was given it. Carrying it farther out, it again acquired polarity to A and B, but in the opposite direction; for it now arranged itself in a position that was parallel to NS, but its north pole was next to N, and its south pole to S.

This singular appearance naturally excited his attention. The line on which the magnets A and B were placed had been marked on the table, as also the line DF perpendicular to the former. The point E was now marked as an important one. The experiments were interrupted by a friend coming in, to whom such things were no entertainment. Next day, wishing to repeat them to some friends, the magnets A and B were again laid on the line on which they had been placed the day before, and the needle was placed at E, expecting it to be neutral. But it was found to have a considerable verticity, turning its north pole toward the magnet B; and it required to be taken farther out, toward F, before it became neutral. While standing there, something chanced to joggle the magnets A and B, and they instantly rushed together. At the same instant, the little magnet or needle turned itself briskly, and arranged itself, as it had done the day before, at F, quivering very briskly, and thus shewing great verticity. This naturally surprised the beholders; and we now found that, by gradually withdrawing the magnets A and B from each other, the needle became weaker—then became neutral—and then turned round on its pivot, and took the contrary position. It was very amusing to observe how the simply separating the magnets A and B, or bringing them together, made the needle assume such a variety of positions and degrees of vivacity in each.

The needle was now put in various situations, in respect to the two great magnets; namely, off at a side, and not in the perpendicular DF. In these situations, it took an inconceivable variety of positions, which could not be reduced to any rule; and in most of them, it required only a motion of one of the great magnets for an inch or two, to make the needle turn briskly round on its pivot, and assume a position nearly opposite to what it had before.

But all this was very puzzling, and it was not till after several months, that the writer of this article, having conceived the notion of the magnetic curves, was in a condition to explain the phenomena. With this assistance, however, they are very clear, and very instructive.

Nothing hinders us from supposing the magnets A and B perfectly equal in every respect. Let NHM, NEL, be two magnetic curves belonging to A; that is, such that the needle arranges itself along the tangent of the curve. Then the magnet B has two curves SGK, SEI, perfectly equal, and similar to the other two. Let the curves NHM and SGK intersect in C and F. Let the curves NEL and SEI touch each other in E.

The needle being placed at C, would arrange itself in the tangent of the curve KGS, by the action of B alone, having its north pole turned toward the south pole S of B. But, by the action of A alone, it would be a tangent to the curve NHM, having its north pole turned away from N. Therefore, by the combined action of both magnets, it will take neither of these positions, but an intermediate one, nearly bisecting the angle formed by the two curves, having its north pole turned toward B.

But remove the needle to F. Then, by the action of the magnet A, it would be a tangent to the curve FM, having its north pole toward M. By the action of B, it would be a tangent to the curve KFG, having its north pole in the angle MFG, or turned toward A. By their joint action, it takes a position nearly bisecting the angle GFM, with its north pole toward A.

Let the needle be placed in E. Then, by the action of the magnet A, it would be a tangent to the curve NEL, with its north pole pointing to F. But, by the action of B, it will be a tangent to SEI, with its north pole pointing to D. These actions being supposed equal and opposite, it will have no verticity, or will be neutral, and retain any position that is given to it.

The curve SEI intersects the curve NHM in P and Q. The same reasoning shews, that when the needle is placed at P, it will arrange itself with its north pole on the angle SPH: but, when taken to Q, it will stand with its north pole in the angle EQM.

From these facts and reasonings we must infer, that, for every distance of the magnets A and B, there will be a series of curves, to which the indefinitely short needle will always be a tangent. They will rise from the adjoining poles on both sides, crossing diagonally the lozenges formed by the PRIMARY or SIMPLE curves, as in fig. 6. These may be called COMPOUND or SECONDARY magnetic curves. Moreover, these secondary

condary curves will be of two kinds, according as they pass through the first or second intersections of the primary curves and the needle will have opposite positions when placed on them. These two sets of curves will be separated by a curve GEH, in the circumference of which the needle will be neutral. This curve passes through the points where the primary curves touch each other. We may call this the *line of neutrality* or inactivity.

We now see distinctly the effect of bringing the magnets A and B nearer together, or separating them farther from each other. By bringing them nearer to each other, the point E, which is now a point of neutrality, may be found in the *second* intersection (such as F) of two magnetic curves, and the needle will take a subcontrary position. By drawing them farther from each other, E may be in the *first* intersection of two magnetic curves, and the needle will take a position similar to that of C.

If the magnets A and B are not placed so as to form a straight line with their four poles, but have their axes making an angle with each other, the contacts and intersections of their attending curves may be very different from those now represented; and the positions of the needle will differ accordingly. But it is plain, from what has been said, that if we knew the law of action, and consequently the form of the primary curves, we should always be able to say what will be the position of the needle. Indeed, the consideration of the simple curves, although it was the mean of suggesting to the writer of this article the explanation of those more complicated phenomena, is by no means necessary for this purpose. Having the law of magnetic action, we must know each of the eight forces by which the needle is affected, both in respect of direction and intensity; and are therefore able to ascertain the single force arising from their composition.

ondary
es of
ulsion.

When the similar poles of A and B are opposed to each other, it is easy to see, that the position of the needle must be extremely different from what we have been describing. When placed anywhere in the line DF, between two magnets, whose north poles front each other in N and S, its north pole will always point away from the middle point D. There will be no neutral point E. If the needle be placed at P or Q, its north pole will be within the angle EPH, or FQI. This position of the magnets gives another set of secondary curves, which also cross the primary curves, passing diagonally through the lozenges formed by their intersection. But it is the other diagonal of each lozenge which is a chord to those secondary curves. They will, therefore, have a form totally different from the former species.

The consideration of this compounded magnetism is important in the science, both for explaining complex phenomena, and for advancing our knowledge of the great desideratum, the law of magnetic action. It serves this purpose remarkably. By employing a very small needle, the points of neutrality ascertain very nearly where the magnetic curves have a common tangent, and shews the position of this tangent. By placing the two magnets so as to form various angles with each other, we can, by means of these neutral points, know the position of the tangent in every point of the curve, and thus can ascertain the form of the curve, and the law of action, with considerable accuracy. The writer of this article took this method; and the result confirmed him in the opinion, that it was in the inverse duplicate ratio of the distances. The chief (perhaps the only) ground of error seemed to be the difficulty of procuring large magnets, having the action of each pole very much concentrated. Large magnets must be employed. He attempted to make such, consisting of two spherical balls, joined by a slender rod. But he could not give a strong magnetism to magnets of this form, and was forced to make use of common bars, the poles of which are considerably diffused. This diffusion of the pole renders it very difficult to select with propriety the points from which the distances are to be estimated, in the investigation of the relation between the forces and distances.

He tried another method for ascertaining this so much desired law, which had also the same result. Having made a needle consisting of two balls joined by a slender rod, and having touched it with great care, so that the whole strength of its poles seemed very little removed from the centres of the balls, he counted the number of horizontal vibrations which it made in a given time by the force of terrestrial magnetism. He then placed it on the middle of a very fine and large magnet, placed with its poles in the magnetic meridian, the north pole pointing south. In this situation he counted the vibrations made in a given time. He then raised it up above the centre of the large magnet, till the distance of its poles from those of the great magnet were changed in a certain proportion. In this situation its vibrations were again counted. It was tried in the same way in a third situation, considerably more remote from the great magnet. Then, having made the proper reduction of the forces corresponding to the obliquity of their action, the force of the poles of the great magnet was computed from the number of vibrations. To state here the circumstances of the experiment, the necessary reductions, and the whole computations, would occupy several pages, and to an intelligent reader would answer little purpose. Mr Lambert's excellent dissertation in the 22d vol. of the *Mem. de l'Acad. de Berlin*, will shew the prolixity and intricacy of this investigation. Suffice it to say, that these experiments were the most consistent with each other of any made by the writer of this article, with the view of ascertaining the law of magnetic action; and it is chiefly from their result that he thinks himself authorised to say, with some confidence, that it is inversely as the square of the distance. These experiments were first made in a rough way in 1769 and 1772. In 1775, observing that Mr Æpinus seemed to think the action inversely as the distance (see his *Tentam. Theor. Electr. et Magn.* § 301. &c.), they were repeated with very great care; and to these were added another set of experiments, made with the same magnet and the same needle, placed not above the magnet, but at one side (but always in the line through the centre, perpendicular to the axis, so that the actions of the two poles might be equal). This disposition evidently simplifies the process exceedingly. The result of the whole was still more satisfactory. This conclusion is also confirmed by the experiments of Mr Coulomb in the Memoirs of the Academy of Sciences at Paris for 1786 and 1787. It would seem therefore to be pretty well established. Another method, which seems susceptible of

 considerable

confiderable accuracy, ftill remains to be tried. It will be mentioned in due time.

Such then are the general laws obferved in the mutual action of magnets. We think it fcarcely neceffary to enter into a farther detail of their confequences, correfponding to the innumerable varieties of pofitions in which they may be placed with refpect to each other. We are confident, that the fenfible actions will always be found agreeable to the legitimate confequences of the general propofitions which we have eftablifhed in the preceding paragraphs. We proceed therefore to confider fome phyfical facts not yet taken notice of, which have great influence on the phenomena, and greatly affift us in our endeavours to underftand fomething of their remote caufe.

31 ...netifm ...mpora... pe- Magnetifm, in all its modifications of attraction, repulfion, and direction, is, in general, of a temporary or perifhing nature. The beft loadftones and magnets, unlefs kept with care, and with attention to certain circumftances, are obferved to diminifh in their power. Natural loadftones, and magnets made of fteel, tempered as hard as poffible, retain their virtue with greateft obftinacy, and feldom lofe it altogether, unlefs in fituations which our knowledge of magnetifm teaches us to be unfavourable to its durability. Magnets of tempered fteel, fuch as is ufed for watch-fprings, are much fooner weakened, part with a greater proportion of their force by fimple keeping, and finally retain little or none. Soft fteel and iron lofe their magnetifm almoft as foon as its producing caufe is removed, and cannot be made to retain any fenfible portion of it, unlefs their metallic ftate fuffer fome change.

1. Nothing tends fo much to impair the power of a magnet as the keeping it in an improper pofition. If its axis be placed in the magnetic direction, but in a contrary pofition, that is, with the north pole of it where the fouth pole tends to fettle, it will grow weaker from day to day; and unlefs it be a natural loadftone, or be of hard tempered fteel, it will, after no very long time, lofe its power altogether.

2. This diffipation of a ftrong magnetic power is greatly promoted by heat. Even the heat of boiling water affects it fenfibly; and if it be made red hot, it is entirely deftroyed. This laft fact has long been known. Dr Gilbert tried it with many degrees of violent heat, and found the confequences as now ftated; but having no thermometers in that dawn of fcience, he could not fay any thing precife. He only obferves, that it is deftroyed by a heat not fufficient to make it vifible in a dark room. Mr Canton found even boiling water to weaken it; but on cooling again the greateft part was recovered.

3. What is more remarkable, magnetifm is impaired by any rough ufage. Dr Gilbert found, that a magnet which he had impregnated very ftrongly, was very much impaired by a fingle fall on the floor; and it has been obferved fince his time, that falling on ftones, or receiving any concuffion which caufes the magnet to ring or found, hurts it much more than beating it with any thing foft and yielding. Grinding a natural loadftone with coarfe powders, to bring it into fhape, weakens it much; and loadftones fhould therefore be reduced into a fhape as little different from their natural form as poffible; and this fhould be done brifkly, cutting them with the thin difks of the lapidary's wheel, cutting off only what is neceffary for leaving their moft active parts or poles as near their extremities as we can.

All thefe caufes of the diminution of magnetifm are more operative if the magnet be all the while in an improper pofition.

4. Laftly, magnetifm is impaired and deftroyed by placing the magnet near another magnet, with their fimilar poles fronting each other. We have had occafion to remark this already, when mentioning the experiments made with magnets in this pofition, for afcertaining the general laws or variations of their repulfion. We there obferved, that magnets fo fituated always weakened each other, and that a powerful magnet often changed the fpecies of the neareft pole of one lefs powerful. This change is recovered, in part at leaft, when it has taken place in a loadftone or a magnet of hard fteel; but in fpring tempered fteel the change is generally permanent; and almoft to the full extent of its condition while the magnets are together. It is to be remarked, that this change is gradual; and is expedited by any of the other caufes, particularly by heat or by knocking. 4. By other magnets.

32 Magnetifm may be acquired,

On the other hand, magnetifm is acquired by the fame means, when fome other circumftances are attended to:

1. By magnetical pofition; 1. A bar of iron, which has long ftood in the magnetic direction, or nearly fo, will gradually acquire magnetifm, and the ends will acquire the polarity correfponding to their fituation. In this country, and the north of Europe, the old fpindles of torret vanes, old bars of windows, &c. acquire a fenfible magnetifm; their lower extremity becoming a north pole, and the other end a fouth pole. Gilbert fays, that this was firft obferved in Mantua, in the vane fpindle of the Auguftine church—"*Venia flexa* (fays he) *de prompta, et apothecario cuidam conceffa, attrahebat ferrea ramenta, vel perquam infignis.*" The upper bar of a hand rail to a ftair on the north fide of the higheft part of the fteeple of St Giles's church in Edinburgh is very magnetical; and the upper end of it, where it is lodged in the ftone, is a vigorous fouth pole. It is worth notice, that the parts of fuch old bars acquire the ftrongeft magnetifm when their metallic ftate is changed by expofure to the air, becoming foliated and friable. It would be worth while to try, whether the æthiops martialis, produced by fteam in the experiments for decompofing water, will acquire magnetifm during its production. The pipe and the wires, which are converted into the fhining æthiops, fhould be placed in the magnetic direction.

2. By hammering; 2. If a bar of fteel be long hammered while lying in the magnetic direction, it acquires a fenfible magnetifm (See Dr Gibert's plate, reprefenting a blackfmith hammering a bar of iron in the magnetic direction). The points of drills, efpecially the great ones, which are urged by very great preffure; and broaches, worked by a long lever, fo as to cut the iron very faft, acquire a ftrong magnetifm, and the lower end always becomes the north pole (*Phil. Tranf.* xx 417.) Even driving a hard fteel punch into a piece of iron, gives it magnetifm by a fingle blow. In fhort, any very violent fqueeze given to a piece of tempered fteel renders it magnetic, and its polarity correfponds with its pofition during the experiment. We can fcarcely take up a cutting or boring tool in a fmith's fhop that is not magnetical. Even

fofs

soft steel and iron acquire permanent magnetism in this way. Iron also acquires it by twisting and breaking. It is therefore difficult to procure pieces of iron or steel totally void of determinate and permanent magnetism; and this frequently mars the experiments mentioned in the first paragraphs of this article. The way therefore to ensure success in these experiments is to deprive the rods of their accidental magnetism, by some of the methods mentioned a little ago. Let them be heated red hot, and allowed to cool while lying in a direction perpendicular to the magnetic direction (nearly E. N. E. and W. S. W. in this country).

y heat. 3. As heat is observed to destroy magnetism, so it may also be employed to induce it on substances that are susceptible of magnetism. Dr Gilbert makes this observation in many parts of his work. He says, that the ores of iron which are in that particular metallic state which he considers as most susceptible of magnetism, will acquire it by long continuance in a red heat, if laid in the magnetic direction, and that their polarity is conformable to their position, that end of the mass which is next the north becoming the north pole. He also made many experiments on iron and steel bars exposed to strong heats in the magnetical direction. Such experiments have been made since Gilbert's time in great number. Dr Hooke, in 1684, made experiments on rods of iron and steel one fifth of an inch in diameter, and seven inches long. He found them to acquire permanent magnetism by exposure to strong heat in the magnetic direction, and if allowed to cool in that direction. But the magnetism thus acquired by steel rods was much stronger, and more permanent, if they were suddenly quenched with cold water, so as to temper them very hard. He found, that the end which was next to the north, or the lower end of a vertical bar, was always its permanent north pole. Even quenching the upper end, while the rest was suffered to cool gradually, became a very sensible south pole. No magnetism was acquired if this operation was performed on a rod lying at right angles to the magnetical direction.

In these trials the polarity was always estimated by the action on a mariner's needle, and the intensity of the magnetism was estimated by the deviation caused in this needle from its natural position. Dr Gilbert made a very remarkable observation, which has since been repeated by Mr Cavallo, and published in the Philosophical Transactions as a remarkable discovery. Dr Gilbert says, p. 69. "*Bacillum ferreum, valide ignitum appone versorio excito; stat versorium, nec ad tale ferrum convertitur: sed statim ut primum de candore aliquantulum remiserit, confluit illico.*" In several other parts of his treatise he repeats the same thing with different circumstances. It appears, therefore, that while iron is red hot, it is not susceptible of magnetism, and that it is during the cooling in the magnetic direction that it acquires it. Gilbert endeavoured to mark the degree of heat most favourable for this purpose; but being unprovided with thermometers, he could not determine any thing with precision. He says, that the versorium, or mariner's needle, was most deranged from its natural position a little while after the bar of iron ceased to shine in day-light, but was still pretty bright in a dark room. But there are other experiments which we have made, and which will be mentioned by and bye; by which it appears, that although a bright red or a white heat makes iron unsusceptible of magnetism while in that state, it predisposes it for becoming magnetical. When a bar of steel was made to acquire magnetism by tempering it in the magnetical direction, we found that the acquired magnetism was much stronger when the bar was made first of all very hot, even although allowed to come to its most magnetical state before quenching, than if it had been heated only to that degree; nay, we always found it stronger when it was quenched when red hot. We offer no explanation at present; our sole business just now being to state facts, and to generalize them, in the hopes of finding some fact which shall contain all the others.

4. The most distinct acquisitions and changes of magnetism are by juxtaposition to other magnets and to iron. 4. As the magnetism of a loadstone or magnet is weakened by bringing its pole near the similar pole of another magnet, it is improved by bringing it near the other pole; and it is always improved by bringing it near any piece of iron or soft steel.

But this action, and the mutual relation of magnets and common iron, being the most general, and the most curious and instructive of all the phenomena of magnetism, they merit a very particular consideration.

Of the communication of Magnetism.

The whole may be comprehended in one proposition, which may be said to contain a complete theory of magnetism. 33 Communication of magnetism.

Fundamental proposition.

Any piece of iron, when in the neighbourhood of a magnet, is a magnet, and its polarity is so disposed that the magnet and it mutually attract each other.

The phenomena which result from this fundamental principle are infinitely various, and we must content ourselves with describing a simple case or two, which will sufficiently enable the reader to explain every other.

Take a large and strong magnet NAS (fig. 7.), of which N is the north, and S the south pole. Let it be properly supported in a horizontal position, with its poles free, and at a distance from iron or other bodies. 34 Operative powers illustrated. Take any small piece of common iron, not exceeding two or three inches in length, such as a small key. Take also another piece of iron, such as another smaller key, or a bit of wire about the thickness of an ordinary quill.

1. Hold the key horizontally, near one of the poles, (as shewn at n° 1.), taking care not to touch the pole with it; and then bring the other piece of iron to the other end of the key (it is indifferent which pole is thus approached with the key, and which end of the key is held near the pole). The wire will hang by the key, and will continue to hang by it, when we gradually withdraw the key horizontally from the magnet, till, at a certain distance, the wire will drop from the key, because the magnetism imparted from this distance is too weak. That this is the sole reason of its dropping, will appear by taking a shorter, or rather a slenderer, bit of wire, and touch the remote end of the key with it: it will be supported, even though we remove the key still farther from the magnet.

2. Hold the key *below* one of the poles, as at n° 2. or 3. and touch its remote end with the wire. It will be suspended in like manner, till we remove the key too far from the magnet.

3. Hold

3. Hold the key *above* the poles, as at nº 4. or 5. and touch its adjacent end with the wire (taking care that the wire do not alſo touch the magnet). The wire will ſtill be ſupported by the key, till both are removed too far from the magnet.

Thus it appears, that in all theſe ſituations the key has ſhewn the characteriſtic phenomenon of magnetiſm, namely, attraction for iron. In the experiment with the key held above the pole, the wire is in the ſame ſituation in reſpect to magnetiſm as the key is when held below the pole; but the actions are mutual. As the key attracts the wire, ſo the wire attracts the key.

If the magnet be ſupported in a vertical poſition, as in fig. 8. the phenomena will be the ſame; and when the key is held directly above or directly below the pole, it will carry rather a heavier wire than in the horizontal poſition of the magnet and key.

Inſtead of approaching the magnet with the key and wire, we may bring the magnet toward them, and the phenomena will be ſtill more palpable. Thus, if the bit of wire be lying on the table, and we touch one end of it with the key, they will ſhew no connection whatever. While we hold the key very near one end of the wire, bring down the pole of a magnet toward the key, and we ſhall then ſee the end of the wire riſe up and ſtick to the key, which will now ſupport it. In like manner, if we lay a quantity of iron filings on the table, and touch them with the key, in the abſence of the magnet, we find the key totally inactive. But, on bringing the magnet anyhow near the key, it immediately attracts the iron filings, and gathers up a heap of them.

In the next place, this vicinity of a magnet to a piece of iron gives it a directive power. Let NAS (fig. 9.) be a magnet, and BC (nº 1.) a key held near the north pole, and in the direction of the axis. Bring a very ſmall mariner's needle, ſupported on a ſharp point, near the end C of the key which is fartheſt from N. We ſhall ſee this needle immediately turn its ſouth pole towards C, and its north pole away from C. This poſition of the needle is indicated at *c*, by marking its north pole with a dart, and its ſouth with a croſs. Thus it appears that the key has got a directive power like a magnet, and that the end C is performing the office of a north pole, attracting the ſouth pole of the needle, and repelling its north pole. It may indeed be ſaid, that the needle at *c* arranges itſelf in this manner by the directive power of the magnet; for it would take the ſame poſition although the key were away. But if we place the needle at *b*, it will arrange itſelf as there repreſented, ſhewing that it is influenced by the key, and not (wholly at leaſt) by the magnet. In like manner, if we place the needle at *a*, we ſhall ſee it turn its north pole toward B, notwithſtanding the action of the magnet on it. This action evidently tends to turn its north pole quite another way; but it is influenced by B, and B is performing the office of a ſouth pole.

In like manner, it we place the key as at nº 2. we ſhall obſerve the end B attract the ſouth pole of the needle placed at *a*, and the end C attract the north pole of a needle placed in *b*. In this ſituation of the key, we ſee that B performs the office of a north pole, and C performs the office of a ſouth pole.

Thus it appears that the key in both ſituations has become a magnet, poſſeſſed of both an attractive and a directive power. It has acquired two poles.

Laſtly, the magnetiſm of the key is ſo diſpoſed, that the two magnets NAS and BC muſt mutually attract each other; for their diſſimilar poles front each other. Now, it is a matter of uniform and uncontradicted obſervation, that when a piece of iron is thus placed near a magnet, and the diſpoſition of its magnetiſm is thus examined by means of a mariner's needle, the diſpoſition is ſuch that two permanent magnets with their poles ſo diſpoſed muſt attract each other. The piece of iron, therefore, having the ſame magnetic relation to the magnet that a ſimilar and ſimilarly diſpoſed magnet has, muſt be affected in the ſame manner. We cannot, by any knowledge yet contained in this article, give any preciſe intimation in what way the polarity of the piece of iron will be diſpoſed. This depends on its ſhape as much as on its poſition. By deſcribing two or three examples, a notion is obviouſly enough ſuggeſted, which, although extremely gratuitous, and perhaps erroneous, is of ſervice, becauſe it has a general analogy with the obſerved appearances.

The attraction of iron is owing to the diſpoſition of its own temporary magnetiſm.

If one end of a ſlender rod or wire be held near the north pole of the magnet, while the rod is held in the direction of the axis (like the key in fig. 7. nº 1.), the near end becomes a ſouth, and the remote end a north pole. Keeping this ſouth pole in its place, and turning the rod in any direction from thence, as from a centre, the remote end is always a north pole. And, in general, the end of any oblong piece of iron which is neareſt to the pole of a magnet becomes a pole of the oppoſite name, while the remote end becomes a pole of the ſame name with that of the magnet.

If the iron rod be held perpendicularly to the axis, with its middle very near the north pole of the magnet, the two extremities of the iron become north poles, and the middle is a ſouth pole.

If the north pole of a magnet be held perpendicular to the centre of a round iron plate, and very near it, this plate will have a ſouth pole in its centre, and every part of its circumference will have the virtue of a north pole.

If the plate be ſhaped with points like a ſtar, each of theſe points will be a very diſtinct and vigorous north pole.

Something like this will be obſerved in a piece of iron of any irregular ſhape. The part immediately adjoining to the north pole of the magnet will have the virtue of a ſouth pole, and all the remote protuberances will be north poles.

The notion naturally ſuggeſted by theſe appearances is, that the virtue of a north pole ſeems to reſide in ſomething that is moveable, and that is protruded by the north pole of the magnet toward the remote parts of the iron; and is thus conſtipated in all the remote edges, points, and protuberances, much in the ſame manner as electricity is obſerved to be protruded to the remote parts and protuberances of a conducting body by the preſence of an overcharged body. This notion will greatly aſſiſt the imagination; and its conſequences very much reſemble what we obſerve.

As a farther mark of the complete communication of every magnetic power by mere vicinity to a magnet, we may here obſerve, that the wire D, of fig. 7. nº 2. and 3. will ſupport another wire, and this another; and ſo on,

on, to a number depending on the ſtrength of the magnet. The key has therefore become a true magnet in every reſpect; for it induces complete magnetiſm on the appended wire. That this is not the ſame operation of the great magnet (at leaſt not wholly ſo), appears by examining the magnetiſm of D with the needle, which will be ſeen to be more influenced by D than by A. This fact has been long known. The ancients ſpeak of it: They obſerve, that a loadſtone cauſes an iron ring to carry another ring, and that a third; and ſo on, till the ſtring of rings appears like a chain.

37 ception plained.

What has now been ſaid will explain a ſeeming exception to the univerſality of the propoſition. If the key be held in the ſituation and poſition repreſented by fig. 10. the bit of wire will not be attracted by it; and we may imagine that it has acquired no magnetiſm: But if we bring a mariner's needle, or a bit of wire, near to its remote end B, it will be ſtrongly attracted, and ſhew B to be a north pole. The needle held near to C will alſo ſhew C to be a ſouth pole. Alſo, if held near to D, it will ſhew D to be a north pole. Now the ends C, both of the key and of the wire, being ſouth poles, they cannot attract each other, but, on the contrary, they will repel; and therefore the wire will not adhere to the key. And if the key of fig. 17. n° 4. with the wire hanging to it, be gradually carried outward, beyond the north pole of the magnet, and then brought down till its lower end be level with the pole, the wire will drop off.

There is, however, one exception to the propoſition. If the key in fig. 7. with its appending wire D, be gradually carried from any of the ſituations 3, 4, or 5, toward the middle of the magnet, the wire will drop off whenever it arrives very near the middle. If we ſuppoſe a plane to paſs through the magnetic centre A, perpendicular to the axis (which plane is very properly called the magnetic equatorial plane by Gilbert), a ſlender piece of iron, held any where in this plane, acquires no ſenſible magnetiſm. It gives no indication of any polarity, *and it is not attracted by the magnet*. It is well known, that the activity of a loadſtone or magnet reſides chiefly in two parts of it, which have been called its poles; and that thoſe are the beſt magnets or loadſtones in which this activity is leaſt diffuſed; and that a certain circumference of every loadſtone or magnet is wholly inactive. When a loadſtone or magnet of any ſhape is laid among iron filings, it collects them on two parts only of its ſurface, and between theſe there is a ſpace all round, to which no filings attach themſelves.

We preſume that the reader already explains this appearance to himſelf. Many things ſhew a contrariety of action of the two poles of a magnet. We have already obſerved, that the north pole of a ſtrong magnet will produce a ſtrong northern polarity in the remote end of a ſmall ſteel bar; and, if it be then applied near to that end in the oppoſite direction, it will deſtroy this polarity, and produce a ſouthern polarity. In whatever theſe actions may conſiſt, there is ſomething not only different but oppoſite. They do not blend their effects, as the yellow and blue making rays do in producing green. They oppoſe each other, like mechanical preſſures or impulſions. We have every mark of mechanical action; we have local motion, though unſeen, except in the gradual progreſſion of the magnetical faculties along the bar; but we have it diſtinctly in the ultimate effect, the approach or receſs of the magnets: and in theſe phenomena we ſee plainly, that the forces, in producing their effects, act in oppoſite directions. Whatever the internal inviſible motions may be, they are compoſed of motions whoſe equivalents are the ſame with the equivalents of the ultimate, external, ſenſible motions; therefore the internal motions are oppoſite and equal if the ſenſible motions are ſo, and converſely.

Adopting this principle, therefore, that the actions of the two poles are not only different but oppoſite, it follows, that if they are alſo equal and act ſimilarly, each muſt *prevent* the action of the other; and that there will be a mechanical equilibrium—it may even be called a magnetical equilibrium. Therefore if every part of a ſlender rod, or of a thin plate of iron, lie in the plane of the magnetic equator, the magnetic ſtate (in whatever it may conſiſt) cannot be produced in it. It will exhibit no magnetiſm; have no polar faculties; and we can ſee no reaſon why it ſhould be attracted by the magnet, or ſhould attract iron. We muſt not forget to obſerve in this place, that iron in a ſtate of incandeſcence acquires no magnetiſm by juxtapoſition. We have already remarked, that iron in this ſtate does not affect the magnet. If a bar of red hot iron be ſet near a mariner's needle, it does not affect it in the ſmalleſt degree till it almoſt ceaſes to appear red hot in day light, as has been obſerved by Dr Gilbert. All actions that we know are accompanied by equal and oppoſite re-actions; and we ſhould expect, what really happens in the preſent caſe, namely, that red hot iron ſhould not be rendered magnetical and attractable.

There is a very remarkable circumſtance which accompanies the whole of this communication of magnetiſm to a piece of iron. It does not impair the power of the magnet; but, on the contrary, improves it. This fact was obſerved, and particularly attended to, by Dr Gilbert. He remarks, that a magnet, in the hands of a judicious philoſopher, may be made to impart more magnetiſm than it poſſeſſes to each of ten thouſand bars of ſteel, and that it will be more vigorous than when the operations began. A magnet (ſays he) may be ſpoiled by injudicious treatment with other magnets, but never can touch a piece of common iron without being improved by it. He gives a more direct proof. Let a magnet carry as heavy a lump of iron as poſſible by its lower pole. Bring a great lump of iron cloſe to its upper pole, and it will now carry more. Let it be loaded with as much as it can carry while the lump of iron touches its upper pole. Remove this lump, and the load will inſtantly drop off. But the following experiment ſhews this truth in the moſt convincing manner:

Let NAS (fig. 11.) be a magnet, not very large, nor of extreme hardneſs. Let CD be a ſtrong iron wire, hanging perpendicularly from a hook by a ſhort thread or loop. The magnet, by its action on CD, renders D a north pole and C a ſouth pole, and the polarity of D's magnetiſm fits it for being attracted. Let it aſſume the poſition C *e*, and let this be very carefully marked. Now bring a great bar of iron *s* B near to the other end of the magnet. We ſhall inſtantly perceive the wire C *e* approach to the ſouth pole of the magnet, taking a poſition C *f*. Withdraw the bar of iron, and C *f* will fall back into the poſition C *e*. As we bring the iron bar gradually nearer to the magnet, the

the wire will deviate farther from the perpendicular, and when the bar B touches the magnet CD, will start a great way forward. It is also farther to be observed, that the larger the bar of iron is, the more will CD deviate from the perpendicular.

Now this must be ascribed to the action of the bar on the magnet. For if the magnet be removed, the bar alone will make no sensible change on the position of the wire. We know that the bar of iron becomes magnetical by the vicinity of the magnet. If we doubt this, we need only examine it by means of a piece of iron or a mariner's needle. This will shew us that *s* has become a south, and *n* a north pole. Here then are two magnets with their dissimilar poles fronting each other. In conformity with the whole train of magnetical phenomena, we must conclude that they attract each other, and must improve each other's magnetism.

This is a most important circumstance in the theory of magnetism. For it shews us, that, in rendering a piece of iron magnetic, there is no material communication. There is no indication of the transference of any substance residing in the magnet into the piece of iron; nor is there even any transference of a power or quality. Were this the case, or if the substance or quality which was in A be now transferred to B, it can no longer be in A; and therefore the pheonomena resulting from its presence and agency must be diminished. We must say that the magnet has excited powers inherent, but dormant, in the iron; or is, at least, the occasion of this excitement, by disturbing, in some adequate manner, the primitive condition of the iron. We must also say, that the competency of the magnet and of the iron to produce the phenomena, is owing to the same circumstances in both; because we see nothing in the phenomena which authorises us to make any distinction between them. Whatever therefore causes one magnet to attract another, is also the reason why a piece of iron in the neighbourhood of a magnet attracts another piece of iron; and we must say that the cause of polarity, or the origin of the directive power, is the same in both. Now we understand perfectly the directive power of a magnet, as exerted on another magnet. We see that it arises from a combination and mechanical composition of attractions and repulsions. It must be the same in this magnetism now inherent in the iron. The piece of iron directs a mariner's needle, as a magnet would direct it; therefore, as there is something in a piece of iron which *now* attracts something in another piece of iron, so there is something in the first which repels something in the last.

It may indeed be said that it is not a piece of iron, but a mariner's needle, or magnet, that is thus directed by our iron magnetised by vicinity to a magnet. This objection is completely removed by the most curious of all the facts which occur in this manner of producing magnetism. Take a piece of common iron, fashion it, and fit it up precisely like a mariner's needle, and carefully avoid every treatment that can make it magnetical. Set it on its pivot, and bring it near the north pole of a magnet, placing the end, made like the south pole of the needle, next to the north pole of the magnet. In short, place it by hand exactly as a real mariner's needle would arrange itself. It will retain that position. Now carry it round the magnet, along the circumference of a magnetic curve, or in any regular and continuous route. This piece of iron will, in every situation, assume the very same position or attitude which the real magnetical needle would assume if in the same place, and it will oscillate precisely in the same way.

Here then it is plain, that there is no distinction of power between the magnetism of the iron and of the real needle. To complete the proof: Instead of approaching the magnet with this iron needle, bring it into the vicinity of a piece of iron, which is itself magnetical only by vicinity to a magnet, it will arrange itself just as the real needle would do, with the sole difference, that it does not indicate the *kind* of polarity existing in the extremities of the iron, because either end of it will be attracted by them. And this circumstance leads us to the consideration of the only distinction between the magnetism of a loadstone or magnet and that of common iron.

41 Magnetism of iron is transitory and indifferent; but that of magnets is durable and determinate.

The magnetism of common iron is momentary, and therefore indifferent; whereas that of a magnet is permanent and determinate. When iron becomes magnetic in the way now mentioned, it remains so only while the magnet remains in its place; and when that is removed, the iron exhibits no signs of magnetism. Therefore when the north pole of a magnet has produced a south pole in the nearest end of an iron wire, and a north pole at the remote end, if we turn the magnet, and present its south pole, the nearest end of the wire instantly becomes a north pole, and the other a south pole; and this change may be made as often, and as rapidly, as we please. This is the reason which made us direct the experimenter on the iron needle to begin his operation by placing the end marked for a south pole next to the north pole of the magnet. It becomes a real south pole in situation, and acts as such during its peregrination round the magnet. But in any one of its situations, if we turn it half round with the finger, the end which formerly turned away from a pole of the magnet, will now turn as vigorously toward it. Therefore, in carrying the iron needle round the magnet, we directed the progress to be made in a continuous line, to avoid all chance of mistaking the polarities.

Magnetism of Induction.

For all the reasons now adduced, we think ourselves obliged to say, that the magnetism produced on common iron by mere juxtaposition to a magnet, is generated *without* any *communication* of substance or faculty. The power of producing magnetical phenomena is not *shared* between the magnet and the iron. We shall call it INDUCED MAGNETISM; MAGNETISM BY INDUCTION.

We have said that induced magnetism of common iron is quite momentary. This must be understood with careful limitations. It is strictly true only in the case of the finest and purest soft iron, free of all knots and hard veins, and therefore in its most metallic state. Iron is rarely found in a state so very pure and metallic; and even this iron will acquire permanent and determinate magnetism by induction, if it has been twisted or hammered violently, although not in the magnetic direction; also the changes produced (we imagine) on the purest iron by the action of the atmosphere make it susceptible of fixed magnetism. But the magnetism thus inducible on good iron is scarcely sensible, and of no duration, unless it has lain in the neighbourhood of a magnet for a very long while.

What has now been said of common iron, is also true of it when in the state of soft steel.

But

43 [T]empered [st]eel ac[q]uires du[ra]ble mag[ne]tism.

But any degree of temper that is given to steel makes a very important change in this respect. In the first place, it acquires magnetism more slowly by induction than an equal and similar piece of common iron, and finally acquires less. These differences are easily examined by the deviations which it causes in the mariner's needle from the magnetic meridian, and by its attraction.

When the inducing magnet is removed, some magnetism remains in the steel bar, which retains the polarity which it had in the neighbourhood of the magnet.

Steel tempered to the degree fit for watch springs acquires a strong magnetism, which it exhibits immediately on the removal of the magnet. But it dissipates very fast; and, in a very few minutes, it is reduced to less than one-half of its intensity while in contact with the magnet, and not two thirds of what it was immediately on removal from it. It continues to dissipate for some days, though the bar be kept with care; but the dissipation diminishes fast, and it retains at least one-third of its greatest power for any length of time, unless carelessly kept or injudiciously treated.

Steel tempered for strong cutting tools, such as chisels, punches, and drills for metal, acquires magnetism still more slowly by induction, and [illegible] less of it while in contact with the magnet [illegible] more firmly, and finally [illegible] of what it had acquired.

Steel made as hard as possible is much longer in acquiring all the magnetism which simple juxtaposition can give to it. It acquires less than the former; but it retains it with great firmness, and finally retains a much greater proportion.

Such ores of iron as are [illegible] of magnetism are nearly like hard steel in [illegible], that is in the time necessary for their [illegible], and in the durability of the acquired magnetism. They differ exceedingly [illegible] the degree of power which they can [illegible] by [illegible] juxtaposition, and the varieties seem to depend on [illegible]. We must observe, that [illegible] of magnetism in their natural state. The ordinary ores, consisting of the metal in the state of an oxyd, and combined with sulphur, are not magneticable while remaining in that state. Most ores require roasting, and a sort of cementation, in contact with inflammable substances. This matter is not well understood; but it would seem that complete metallization is far from being the most favourable condition, and that a certain degree of oxydation, and perhaps some other composition, yet unknown, make the best loadstones. But all this is extremely obscure. The late Dr Gowin Knight made a composition which acquired a very strong and permanent magnetism, but the secret died with him. Dr Gilbert speaks of similar compositions, in which ferrugineous clays were ingredients; but we know nothing of the state of the metal in them, nor their mode of acquiring magnetism.

44 [In]duction [of m]agne[tism] is gra[du]al and [pro]gressive.

It is of peculiar importance to remark that the acquisition of magnetism is gradual and progressive, and that the gradation is the more perceptible in proportion as the steel is of a harder temper. When a magnet is brought to one end of a bar of common iron, its remote extremity, unless exceedingly long, acquires its utmost magnetism immediately. But when the north pole of a magnet is applied to one end of a bar of hard steel, the part in contact immediately becomes a south pole, and the far end is not yet affected. We observe a north pole formed at some distance from the contact, and beyond this a faint south pole. These gradually advance along the bar. The remote extremity becomes first a faint south pole, and it is not till after a very long while (if ever) that it becomes a simple, vigorous, north pole. More frequently it remains a diffused and feeble north pole; nay, if the bar be very long, it often happens that we have a succession of north and south poles, which never make their way to the far end of the bar. This phenomenon was first observed (we think) by Dr Brook Taylor, who gives an account of his observations in the *Philosophical Transactions*, nº 344.

From the account we have given of these phenomena of induced magnetism, it appears that the temporary magnetism is always so disposed that the sum of the mutual attractions of the dissimilar poles exceeds the sum of the repulsions between the similar poles, and that therefore the two magnets tend to each other. This is evidently equivalent to saying, that a piece of unmagnetic iron is always attracted by a magnet. No exception has ever been observed to this fact; for Pliny's story of a Theamedes, or loadstone, which repels iron, is allowed by all to have been a fable. Iron is attracted only because it becomes magnetical.

We think ourselves authorised to say that this attraction of the loadstone for iron, or this tendency of iron to the loadstone, is a secondary phenomenon, and is the *consequence* of the proper disposition of the induced magnetism. The proofs already given of the compound nature of this phenomenon, namely, that it arises from the excess of two attractions above two repulsions, need (we imagine) no addition. But the following considerations place the matter beyond doubt:

1. The magnetism of the two poles is evidently of an opposite nature; the one repelling what the other attracts. If the one attracts iron, therefore, the other should repel it. But each pole, by inducing a magnetism opposite to its own, on the nearest end of the iron, and the same with its own on the remote end, and its action diminishing with an increase of distance, there must always be an excess of attraction, and the iron must be attracted.

2. Each of the magnets A and B, in either of the positions represented in fig. 12. would alone attract the piece of common iron C. But when placed together, the south pole of A tends to render the upper end of C a north pole; while the north pole of B tends to make it a south pole. If their actions be nearly equal, the weight of C cannot be supported by the magnetism induced by any difference of action that may remain. While C is hanging by B alone, let A be gradually brought near; it gradually destroys the action of the north pole of B, so that C gradually loses its magnetism and polarity, and its weight prevails.

3. In all those cases where the induction of magnetism is slow, the attraction is weak in proportion. This is particularly remarked by Dr Gilbert. If we take pieces of common iron, and of steel of different tempers, but all of the same size and form, we shall find that the iron is much more strongly attracted than any of the rest, and that the attraction for each of them is weaker in proportion as they are harder. This diversity is so accurately observed, that when the piece is thoroughly

susceptible of magnetism. we can tell, with considerable precision, what degree will be ultimately acquired, and how much will be finally retained. Also, the attraction of the magnet for any of those pieces of steel increases exactly in proportion as their acquired magnetism increases.

4. An ore of iron incapable of acquiring magnetism is not attracted by a magnet. But we know that, by cementation with charcoal dust, they may be rendered susceptible of magnetism. In this state they are attracted. It is an universal fact, that any substance that is attracted by a magnet may be rendered magnetical, and that none else can. We have already observed that red hot iron is not attracted; nor does it acquire any directive power while in that state. From all this we must conclude, that the previous induction of magnetism is the mean of the observed attraction of magnets for iron, and that this is not a primary fact in magnetism.

These observations also complete the proof that magnetic attraction and repulsion are equal at the same distance, and follow the same law. Dr Gilbert seems to think, that the repulsion is always weaker than the attraction; and this is almost the only mistake in conception into which that excellent philosopher has fallen. But it only requires a fair comparison of facts to convince a good logician, that since, *in every case*, and at every distance, either pole of a magnet attracts either end of a piece of common iron, it is impossible that one of these forces can exceed the other. It might be so, were it not that induced magnetism is durable in proper substances. And if we take magnets which have been made such by induction, and present them to each other with their similar poles fronting each other, they never fail to repel each other at considerable distances, and even at very small distances for a few moments; and this is the case whichever poles are next each other. This cannot be on any other supposition. Cases would occur of polarity without attraction, or of attraction without polarity. Such have never been seen, any more than the Theamedes, always repelling iron.

16 Some... of iron ...ls and ...s. Let a great number of small oblong pieces of iron be lying very near each other on the surface of quicksilver. Bring a strong magnet into the midst of them. It immediately renders them all magnetical by induction. The one nearest the north pole of the magnet immediately turns one end toward it, and the other end away from it. The same effect is produced on the one that is just beyond this nearest one. Thus the remote end of the first becomes a north pole, and the nearest end of the second becomes a south pole. These, being very near each other, must mutually attract. The same thing may be said of a third, a fourth; and so on. And thus it appears, that not only is magnetism induced on them all, but also, that the magnetism of each is so disposed, that both ends of it are in a state of attraction for the ends of some of its neighbours; and that they will therefore arrange themselves by coalescence in some particular manner. Should a parcel of them chance to be standing with their centres in a magnetic curve, with their heads and points turned in any ways whatever, the moment that the magnet is brought among them, and set in the axis of that magnetic curve, the whole pieces of this row will instantly turn towards each other, and their ends will adhere together, if they are near enough; otherwise they will only point toward each other, forming a set of tangents to the magnetic curve, reaching from one pole of the magnet to the other.

Or, suppose a vast number of small bits of iron, each shaped like a grain of barley, a little oblong. Let them be scattered over the surface of a table, so near each other as just to have room to turn round. Let a magnet be placed in the midst of them. They will all have magnetism induced on them in an instant; and such as are not already touching others, will turn round (because they rest on the table by one point only), and each will turn its ends to the ends of its neighbours; and thus they will arrange themselves in curves, which will not differ greatly from true magnetic curves (because each grain is very short), issuing from one pole of the magnet, and terminating in the other.

Does not this suggest to the reflecting reader an explanation of that curious arrangement of iron filings round a magnet, which has so long entertained and puzzled both the philosophers and the unlearned, and which has given rise to the Cartesian and other theories of magnetism? The particles of iron filings are little rags of soft iron torn off by the file, and generally a little oblong. These *must* have magnetism induced on them by a magnet; and, while falling through the air from the hand that strews them about the magnet, they are at perfect liberty to arrange themselves magnetically; and *must* therefore arrange themselves, forming on the table curves, which differ very little indeed from the true magnetic curves. Suppose them scattered about the table before the magnet is laid on it. If we pat the table a little, so as to throw it into tremors, this will allow the particles to dance, and turn round on their points of support, till they coalesce by their ends in the manner already described.

All this is the genuine and inevitable consequence of what Dr Gilbert has taught us of induced magnetism. It must be so; and cannot be otherwise. This curious arrangement of iron filings round a magnet is therefore not a primary fact, and a foundation for a theory, but the result of principles much more general.

Most of our readers know that this disposition of iron filings has given rise to the chief mechanical theories which have been proposed by ingenious men for the explanation of all the phenomena of magnetism. An invisible fluid has been supposed to circulate through the pores of a magnet, running along its axis, issuing from one pole, streaming round the magnet, and entering again by the other pole. This is thought to be indicated by those lines formed by the filings. The stream, running also through *them*, or around them, arranges them in the direction of its motion, just as we observe a stream of water arrange the flote grass and weeds. It would require a volume to detail the different manners in which those mechanicians attempt to account for the attraction, repulsion, and polarity of magnetic bodies, by the mechanical impulsion of this fluid. Let it suffice to say, that almost every step of their theories is in contradiction to the acknowledged laws of impulsion. Nay, the whole attempt is against the first rule of all philosophical discussion, never to admit for an explanation of phenomena the agency of any cause which we do not know to exist, and to operate in the very phenomenon. We know of no such fluid; and we can demonstrate, that the genuine effects of its impulsion would be totally unlike the phe-

47 Remarks on the theories by impulsion.

nomenon

nomena of magnetifm. But the proper refutation of thefe theories would fill volumes. Let it fuffice (and to every logician it will abundantly fuffice) to remark, that this phenomenon is but a fecondary fact, depending on, and refulting from, principles much more general, viz. the induction of magnetifm, and the attraction of diffimilar, and repulfion of fimilar, poles.

The above explanation of the curious difpofition of iron filings round a magnet, occurred to the writer of this article while ftudying natural philofophy, on feeing the Profeffor exhibit Mr Henfhaw's beautiful experiment in proof of terreftrial magnetifm *. He at that time imagined himfelf the author, and promifed himfelf fome credit for the thought. But having feen the *Phyfiologia Nova de Magnete* by Dr Gilbert, he found that it had not efcaped the notice of that fagacious philofopher; as will appear paft difpute from the following paffage, as well as fome others, lefs pointed, in that work: "Magnetica frufta (that is, fubftances fufceptible of magnetifm) bene et convenienter intra vires pofita, mutuo cohærent. Ferramenta, præfente magnete (etiamfi magnetem non attingant), concurrunt, folicité fe mutuo quærunt, et amplexantur, et, conjuncta, quafi ferruminantur. Scobs ferrea, vel in pulverem redacta, fiftulis impofita chartaceis—fupra lapidem meridionaliter locata, vel propius tantum [illegible] corpus; et fubito tam multæ partes [illegible] conjunguntur, ferrumque aliud affectat conjunctorum turma et attrahit, ac fi unum tantum et integrum effet ferri bacillum; dirigiturque fupra lapidem in feptentriones et meridiem. Sed cum longius a magnete removeantur (tanquam foluta rurfus) feparantur, et diffluunt fingula corpufcula." B. ii. c. 23.

See VARIATION Cycl. 621.

Mr Æpinus alfo had taken the fame view of the fubject *. It is alfo very clearly conceived and expreffed by the celebrated David Gregory, Savilian Profeffor of aftronomy in the Univerfity of Oxford, in a MS. volume of notes and commentaries, written by him in 1693, on Newton's *Principia*, and ufed by Newton in improving the fecond edition. The MS. is now in the library of the univerfity of Edinburgh. Gregory's words are as follow: "Mihi femper dubium vifum eft num magnetica virtus mechanicé, *i. e.* per impulfum, producatur. Mirum eft, effluvia, quæ ferrum agitare valent, bracteas aureas *interpofitas* ne vel minimum a loco movere. Lucretii et Cartefii theoriam, de fugato intermedio aëre, refutat experimentum infra aquam inftitutum. *Sulci in limatura ferri, magneti in plano cujufvis meridiani circumpofita, non fiunt ab effluviis fecundum ejus canales motis, fed ex inde, quod ipfa ramenta, magnetice excitata, fefe fecundum longitudinem et fecundum polos difponunt.* Ex altera vero parte exinde quod vis magnetica, interveniente flamma aut calore, interrumpatur, quod virga ferrea, vel diuturno fitu perpendiculari, vel in eo fitu frigefcendo, virtutem magneticam a tellure acquirat. ut nos docet perfpicaciffimus Gilbertus. Quod mallei fuper incudem ictu forti ad alterum extremum, virtutem acquirat magneticam; quod ictu forti vel faltem fortiori ad alterum extremum poli permutantur, ut qui prius feptemtriones refpiciebat nunc auftrum refpicit; quod ictu forti ad medium, virtutem illam prorfus amittat. Hæc inquam, et fimilia, mechanicam ejus qualitates ortum arguunt. Hugenius, præter gravitatem, etiam magneticam, et electricam virtutem, aliafque plures experimento novit vires naturales, ut mihi ipfi narravit hac eftate anni 1693. Qualis ut hæc forfitan quod cymba papyracea, prope labia vafis aquam, cui innatet, continentis, pofita, labrum viciniffimum continuo. et cum impetu petat (A)." *Nat. MS. in Prop.* 23. ii. *Prin.*

See § 306.

48 Filings are weakly attracted.

Not only the mere arrangement of the filings in curve lines follows of neceffity from the properties of induced magnetifm, but all the fubordinate circumftances of this phenomenon are included in the fame explanation. By continuing to tap the table, and throw it into tremors, the filings are obferved to approach gradually, but very flowly, to the poles of the magnet. Each particle is a very fmall temporary magnet. The attractive power of the great magnet, $\overline{m-p}-\overline{n-q}$, is therefore extremely fmall in proportion to its directive power, $\overline{m+p}-\overline{n+q}$. And we obferve that the accumulation of the filings round the poles of the magnet is fo much the flower as the filings are finer.

49 Curious fact.

If a paper be laid above the magnet, and the filings be fprinkled on it, we obferve them to conftipate along its edges, while none remain immediately above its fubftance; they are all beyond, or on the outfide of its outline, and they are obferved not to be lying flat on the paper, but to be ftanding obliquely on one point. They move off from the paper immediately above the magnet, becaufe they repel each other. They ftand obliquely from the edges, becaufe that is the direction of a magnetic meridian at its parting from the pole. If the magnet be at fome diftance below the paper, then tapping the paper will caufe the filings to move away from the magnet laterally. This fingular and unexpected appearance is owing to the combination of gravity with the magnetic action. A particle, fuch as *n s* (fig. . .), refts on the paper by the point *n*, which is a temporary north pole (S being fuppofed the fouth pole of the magnet). The particle takes a pofition *n s* nearer to the horizon than the pofition *n o*, which it would take if its centre of gravity *b* were fupported. The pofition is fuch, that its weight, acting vertically at *b*, is in equilibrio with the magnetic repulfion *s d*, exerted between S and *s*. When the paper is tapped, it is beaten down, or withdrawn from *n*, and the particle of iron is left for a moment in the air. It therefore turns quickly round *b*, in order to affume a pofition parallel to *n o*, and it meets the paper, as that rifes again after the ftroke, in a point farther removed from the magnet, and again defcends by its weight (turning round the newly fupported point *n*), till it again takes a pofition parallel to *n s*, but farther off, as reprefented by the dotted line. Thus it travels gradually outwards from the magnet, appearing to be repelled, although it is really attracted by it. If the magnet be held above the paper, at a little diftance, the filings, when we repeatedly pat the paper, gradually collect into a heap under it. This will appear very plainly to one who confiders the fituation of a particle in the manner now explained.

(A) Perhaps it may be proper to obferve, that Dr Gregory expreffes his differing in his opinion from Newton about magnetifm. Newton, in this propofition, thinks, that the law of magnetic action approaches to the inverfe triplicate ratio of the diftance. Dr Gregory invalidates the argument ufed by Newton.

The curve lines formed by very fine filings approach very nearly to the form of the primary curve which indicates the law of magnetic action in the way already explained. If the magnet be placed under water, and if filings be sprinkled copiously on the surface of it from a gauze searce, held at some distance above it, the resistance to their motion through the water gives them time to arrange themselves magnetically before they reach the bottom, and the lines become more accurate. But they were so much deranged by any method that we could take for removing the water, and measuring them, that we were disappointed in our expectations of obtaining a very near approximation to the law of action.

We took notice of some very singular phenomena of a compass needle in the neighbourhood of two magnets, and we observed that, in this case also, the needle was always a tangent to a curve of another kind, and which we called *secondary* and *compound magnetic curves*. These are produced in the same way, by strewing iron filings round the magnets. Many representations have been given of these curves by different authors, particularly by Muschenbroek, in his *Essais de Physique*; and by Fuss in the *Comment. Petropolit.* Great use has been made of these arrangements of filings by two magnets in the theories of magnetism proposed by those who insist on explaining all motion by impulse. When the dissimilar poles of two magnets A and B (fig. 14.) face each other, the curves formed by the filings considerably resemble those which surround a single magnet, and give the whole somewhat of the appearance of a magnet with very diffused poles. The arranging fluid, which streams from one pole of a magnet, is supposed to meet with no obstruction to its entry into the adjoining pole of the other magnet, but, on the contrary, to be impelled into it; and therefore (say the proposers) it circulates round both as one magnet, and by its vortex brings the magnets together; which phenomenon we call the attraction of the magnets. But when the similar poles front each other; for example, the poles from which the arranging fluid issues, then the two streams meet, obstruct each other, accumulate, and, by this accumulation, cause the magnets to recede from each other; which we call the repulsion of the magnets. This is the only explanation of this kind that can make any pretensions to probability, or indeed that can be conceived. For how the free circulation in the former case can bring the two magnets together, no person can form to himself any conception. We see nothing like this produced by any vortex that we are acquainted with. All such vortices cause bodies to separate. But even this explanation of magnetic repulsion is inadmissible. It will not apply to the repulsion of the receiving poles; and the phenomena of the filings are inconsistent with the notion of accumulation. The filings indeed accumulate, and they look not unlike two streams which oppose each other, and deflect to the sides (See fig. 15.): But, unfortunately, by tapping the paper gently, the filings do not move off from the magnets, but approach them much faster than in any other experiment. The phenomenon receives a complete and palpable explanation from the principles we have established. Both magnets concur in giving the same polarity to every particle of the filings. Thus, if the fronting poles are north poles, each particle has its nearest end made a vigorous south pole, and its remote end a north pole; and it is *therefore* strongly attracted towards both magnets while it is arranged in the tangent to the secondary curve of that class, which crosses the others nearly at right angles.

Since it is found, that the magnetism, even of natural loadstones and hard steel, and still more those of softer tempered steel, are continually tending to decay; and since we find that it may be induced by mere approach to a magnet; and since we know that magnets may oppose each other in producing it—it is reasonable to suppose, that when a piece of iron has acquired a slight, though permanent magnetism, by the vicinity of a magnet, a magnet applied in the opposite direction will destroy it, and afterwards produce the opposite magnetism. 52 Magnets must affect each other

Accordingly, we may change the poles of soft magnets at pleasure.

Farther; since we find that loadstones and hard tempered steel bars are distinguished from soft ones only by the *degree* of obstinacy with which they retain their present condition, we should also expect that hard magnets will even affect each other. It must therefore happen, that a powerful magnet applied to a weak one, so that their similar poles are in contact, shall weaken, destroy, and even change the magnetism of the weaker. Dr Knight's famous magazine of magnets enabled him to change the poles of the greatest and the strongest natural loadstone, or artificial magnet, that could be given him, in the space of one minute.

We now see clearly the reason why magnetic repulsion is weaker than attraction at the same distance. 53 Attraction must appear to exceed repulsion. When magnets are placed with their similar poles fronting each other, in order to make trials of their repulsion, they really do weaken each other, and are not in the same magnetical condition as before. For similar reasons, we see how experiments with magnets attracting each other rather improve them, and make their attractive powers appear greater than they are. All these effects must be most remarkable in soft magnets, especially when long.

We also see, that the observed law of attraction and repulsion between two magnets must be different from the real law of magnetic action. 54 The observed law differs from the true. For, in the experiments made on attraction at different distances, beginning with the greatest distance, the magnetism is continually increasing, and the attraction will appear to increase in a higher rate than the just one: the contrary may happen, if we begin with the smaller distances. The results of experiments on repulsion must be still more erroneous; because it is easier to diminish any accumulation which required an exertion to produce it, than to push it still farther.

We have now a complete explanation of the remarkable fact, that the induction of magnetism does not weaken the magnet employed; but, on the contrary, improves it. 55 Magnetism improves by inducing it on iron. The magnetism induced on the iron causes it to act on the magnet employed in the very same manner that a permanent magnet of the same shape, size, and strength, would do. Nay, it will have even a greater effect; for as it improves the magnet, its own induced magnetism will improve; and will therefore still farther improve the magnet.

Hence it is, that, in whatever manner a magnet touches a piece of iron, it improves by it. 56. It may be hurt by a magnet in an improper position; but it always puts common iron into a state which increases its own magnetism.

magnetism. This has been known as long as magnetism itself; and the ancients conceived the notion, that the magnet somehow fed upon the iron (B).

We think that these observations authorise us to say, that in reducing a loadstone into a convenient shape, as much as possible of the operation should be performed by grinding them with emery, in cavities made in large blocks of *hammered* iron. The magnetism induced on the iron must be favourable to the conservation of that in the loadstone; which, we are persuaded, is rapidly dissipated by the tremors into which this very elastic substance is thrown by the grinding with coarse powders in any mould but iron. We imagine, that the cutting off slices by the lapidaries wheel has the same bad effect.

Not only will a magnet lift a greater lump of iron by its north pole, when another lump is applied to its south pole, but it will lift a greater piece of iron from an anvil than from a wooden table; for the magnet induces the properly disposed polarity, not only in the iron which it lifts, but also in the anvil, or any piece of iron immediately beyond it. This is so disposed as to increase the magnetism of the piece of iron between them; and therefore to increase their attraction. The magnetism induced on the anvil is also in part, and perhaps chiefly, induced by the intervening iron. These experiments are extremely variable in their results.—Sometimes a small magnet will pull an iron wire from a large and strong one. Sometimes this will be done even by a piece of unmagnetic iron; and the results appear quite capricious. But they are accurately fixed, depending on the induced compound magnetism. Mr Æpinus has stated some of the more simple cases, in which we can tell which magnet shall prevail. But the unfolding even of these cases would take a great deal of room, and must be omitted here. Besides, we are too imperfectly acquainted with the degree of magnetism induced on the various parts of an iron rod, and the degree of magnetism inherent in the various parts of the magnets, to be able to say, with certainty, even in those simple cases, on which side the superiority of attraction will remain.

58 ting of icial nets.

We may now proceed to deduce from this theory (for so it may justly be called, since all is reduced to one fact) the process for communicating magnetism to bodies fitted for receiving and retaining it; that is, the method of making artificial magnets. We shall not employ much time on this, because the most approved methods have been delivered at length in the article MAGNETISM of the *Encyclopædia Britannica*; and therefore we shall just make such observations on them as serve to confirm, or to perfect them by the theory. We acknowledge, that we do not know the internal process by which magnetism is induced, nor even in what this magnetism consists. All that we know is, that the bringing the pole of a magnet near to any magnetisable matter, produces a magnetism of the kind opposite to that of the pole employed. We know that this is the case with both poles, and that it obtains at all the distances where magnetism is observed. We know that the action of one pole is contrary to that of the other; that is, it counteracts the other, prevents it from producing its effect, and destroys it when already produced: and we know, that the production of these effects resembles in its result the protrusion of something fluid through the pores of the body, constipating it in all remote parts; as if the virtue of a pole resided in this moveable matter. This is nearly all that we know of it; and by these facts and notions we must judge of the propriety and effect of all the processes for magnetising bodies.

The most simple method of magnetising a steel bar, is to apply the north pole of a magnet to that end which we wish to render a south pole. Attention to the effects of this application is very instructive. Have in readiness a very small compass needle, turning on its pivot. It should not exceed half an inch in length, and should be as hard tempered as possible, and strongly impregnated. Immediately after the application of the magnet, carry the needle along the side of the bar. If the bar be long, and very hard, we shall observe a south polarity at the place of contact; a north polarity at a small distance from it; beyond this a weak south polarity; then a weak and diffused north polarity, &c.; toward the remote end the polarity will be found very uncertain. The same thing may be discovered by laying a stiff paper on the bar, and sprinkling iron filings over it, and then gently tapping the paper, to make them arrange themselves in curve lines; which will point out the various poles, and shew whether they are diffused or constipated. It is very amusing and instructive to observe the progress of this impregnation. In a few minutes after the first application of the magnet, we shall perceive the state of magnetism very sensibly changed. The north pole will be farther from the magnet, and will be more distinct; the southern polarity will also be protruded, and may appear for a moment at the remote extremity. The change advances; but the progress is more slow, and at last is insensible. When the bar is not harder than the temper of a cutting tool, the process is soon over; and if the bar is but six or eight inches long, the remote end shews the north polarity in a very few minutes. When the bar is very hard, the progress of impregnation is greatly expedited by striking it so as to make it sound. If it be suspended by a string in a vertical position, and the magnet applied to its lower end, the striking it with a key will make it ring; and in this way make the progress of magnetization very quick: but it does not allow it to acquire all the magnetism that can be given it by a very strong magnet.

But this is a bad way of impregnation. It is seldom that uniform magnetism, with only two poles, and those

(B) So Claudian.——" Nam ferro nutrunt vitam, ferrique vigore
Vescitur, hoc dulces epulas, hoc pabula novit
Hinc proprias renovat vires, hinc fusa per artus
Aspera secretum servant alimenta vigorem
Hoc absente perit, tristi morientia torpent
Membra fame, venasque sitis consumit apertas."

Pliny says, " Sola hæc materia (ferrum) vires ab eo lapide, accipit retinetque longo tempore, aliud apprehendens ferrum, ut annulorum catena spectetur interdum, quod imperitum vulgus ferrum appellat vivum.

of equal ſtrength, can be given. Even when there are but two, the remote pole is generally diffuſed, and therefore feeble. It is much improved by employing two magnets, one at each end. And if the bar is not more than ſix or eight inches long, and good magnets are employed, the magnetiſm is abundantly regular. This, accordingly, is practiſed for the impregnation of dipping needles, which muſt not be touched, leſt we diſturb the centre of gravity of the needle. But in all caſes, this method is tedious, and does not give ſtrong magnetiſm.

The method which was uſually practiſed before we had obtained a pretty clear knowledge of magnetiſm, was to apply the pole of a magnet to one end of the bar, and paſs it along to the other end, preſſing moderately. This was repeated ſeveral times on both ſides of the bar, always beginning the ſtroke at the ſame end as at firſt, and, in bringing the magnet back to that end, keeping it at a diſtance from the bar. The effect of this operation was to leave the end at which we began the ſtroke poſſeſſed of the polarity of the pole employed.

A general notion of the proceſs may be given as follows, obſerving, however, that there occur very many great and capricious anomalies. When the north pole N (fig. 16.) of the magnet A is ſet on the end C of the bar CBD, a ſouth pole is produced at C, and a north pole at D, when the length of the bar is moderate. As the magnet advances ſlowly along the bar, the ſouthern polarity at C firſt increaſes, then diminiſhes, and vaniſhes entirely when N has arrived at a certain point *a*; after which, a northern polarity appears at C, and increaſes during the whole progreſs of the magnet. In the mean time, the northern polarity firſt produced at D increaſes till the magnet reaches a certain point *e*, then diminiſhes, vaniſhes when the magnet reaches a certain point *f*; after which, a ſouthern polarity appears at D, which increaſes till the magnet reaches D. Mr Brugmann, who firſt attended minutely to theſe particulars (for Gilbert ſpeaks of them pointedly), calls *a* and *f points of indifference*, and *e* the *culminating point* of the pole D, and *i* the culminating point of the pole C. Hardly can any general rule be given for the ſituation of theſe points, nor even for the order in which they ſtand; ſo great and capricious are the anomalies in an amazing ſeries of experiments narrated by Brugmann and by Van Swinden. Repeating the operation, and beginning at C, the northern polarity there is weakened (ſometimes deſtroyed), then reſtored, and continually increaſed during the reſt of the ſtroke. The ſouthern polarity at D is alſo firſt weakened, and ſometimes deſtroyed; then reſtored, and finally augmented. The points *i*, *a*, *e*, *f*, change their ſituations, and frequently their order.

Van Swinden has attempted to deduce ſome general laws from his immenſe liſt of experiments, avoiding every conſideration of a hypotheſis, or the leaſt conjecture by what means theſe faculties are excited. But though we have peruſed his inveſtigation with care and candor, we muſt acknowledge, that we have not derived any knowledge which can help us to predict the reſult of particular modes of treatment with any greater preciſion than is ſuggeſted by a ſort of common ſenſe, aided (or perhaps perverted) by a vague notion, that theſe energies reſide in ſomething, which avoids the pole of the ſame name, carrying along with it this diſtinctive energy or polarity. This conception tallies perfectly with theſe obſervations of Brugmann and Van Swinden; and admits of all the anomalies in the ſituation of Bergmann's indifferent and culminating points, if we only ſuppoſe that this motion is obſtructed by the particles of the body. We muſt leave this to the reflection of the reader, who will *gueſs* how, when the magnet is between C and *i*, this ſubſtance, avoiding the pole N of the magnet, eſcapes below it, and goes toward the farther end. As the magnet advances, it drives ſome of this back again, &c. &c. This is gratuitous; but it aids the fancy, which, without ſome conception of this kind, has no object of ſteady contemplation. We have no thought when we ſpeak of the generating at C, or *a*, or *e*, a faculty of ſome kind, by the exertion of the ſame faculty in N. The conception is too abſtracted, and much too complex. We muſt content ourſelves with knowing, that N produces a ſouth pole immediately under it, and a north pole everywhere elſe, or endeavours to do ſo. It is unneceſſary to inſiſt longer on this method: Common ſenſe ſhews it to be a very injudicious one.

This method was greatly improved by beginning the friction at the centre. Apply the north pole at the centre or middle of the bar, and draw it over the end intended for the ſouth pole. Having done this ſeveral times on one end on both ſides, turn the magnet, applying its ſouth pole to the middle of the bar, and drawing it ſeveral times over the end intended for the north pole.

It was ſtill more improved by employing two magnets at once, placed as in fig. 17. on the middle B of the bar, and drawing them away from each other, over the ends of it, as ſhewn by the directing darts, and repeating this operation. It is plain that, as far as we underſtand any thing of this matter, this proceſs muſt be much preferable to either of the former two. The magnets A and E certainly concur in producing a properly diſpoſed magnetiſm on all that lies between them; and therefore on the whole bar at the end of each ſtroke. The end C muſt become a north, and D a ſouth pole. Still, however, as the ſtroke goes on to the point of indifference, each magnet tends to weaken the polarity of the parts ſituated beyond it.

This method continued to be practiſed till about the year 1750. Mr Canton, availing himſelf of the experiments of Mr Mitchell of Cambridge, publiſhed his method by the DOUBLE TOUCH as it is called. See *Monthly Review* for 1785.

We need not repeat what has been detailed in the *Encyclopædia*, MAGNETISM, p. 440, &c., and ſhall only make ſome obſervations on the peculiar advantages of this proceſs, as preſcribed by Mitchell, Canton, and improved by Mr Antheaume, in his memoir *ſur les Aimans artificiels* 1766, which was crowned by the Academy of Sciences. (See alſo diſſertations on the ſubject by *Le Maire and Du Hamel*, 1745). 59 Method of double touch.

There is an evident propriety in the arrangement invented by Mr Mitchell, repreſented in fig. 18. The magnetiſm induced on the two pieces of ſoft iron AD and BC is an excellent method for *ſecuring* every acceſſion of magnetiſm to either of the bars. A good deal depends on the proper ſize and length of theſe pieces; and our ignorance of the interior proceſs obliges us to have recourſe to experiment alone for aſcertaining this. Whatever circumſtances induce the ſtrongeſt magnetiſm

on those pieces of iron, will cause them to produce the greatest effect on the steel bars; and this will be indicated by a greater attraction. Therefore that distance will be the best which enables two bars AB and DC to lift the greatest weight hung on the piece AD or BC. When we impregnated bars whose breadth was about one tenth of their length, and their thickness about one-half of their breadth, we found, that if AD was about one fourth, or nearly one third, of AB, they carried more than if it was either much longer or much shorter. Mr Antheaume's addition of the two great bars of iron E and F makes a sensible improvement of the *beginning* of the impregnation, when very weak magnets are employed; but did not seem to us to be of any farther service on the table. This is agreeable to any theory which can be established by what we have said hitherto.

The method of employing the magnets A and E (fig. 19.), prescribed by Mitchell and Canton, is extremely judicious. The meeting of the dissimilar poles at top increases the magnetism of each. The two dissimilar poles F and G, certainly tend to give a regular and proper magnetism to the part FG of the bar which lies between them; and this is the case on whatever part of the bar they are placed. But each pole tends to destroy the present magnetism of what lies between it and the pole of the bar on that side. But when they tend to produce the desired magnetism on what lies between them with the sum of their forces, while each tends to destroy the magnetism of the part without it by the *difference* only of their forces. Therefore, on the whole, as they are moved to and fro along the bar, and the foremost one even made to pass over the end of it a little way, they always add to the magnetism already acquired. This consideration seems to enjoin setting F and G extremely near each other; for this seems to increase the sum, and to diminish the difference of their action. But it may be a question, Whether we gain more by strongly magnetising a very small part during the very short while that the magnets pass over it, or by acting on more of the bar at once, and continuing a weaker action for a longer while on this larger portion. Mr Æpinus adds another consideration depending on his notion of the internal process; but we defer this to another opportunity. The safest direction seems to be, to place them at the distance which enables them to lift the greatest weight. They are then undoubtedly acting with the greatest effect.

Mr Antheaume directs to place the touching magnets as in fig. 20. for a reason to be mentioned afterwards. Mr Æpinus also recommends it for reasons founded on his own hypothesis. We must say, that, in our trials, we have found this method very sensibly superior, especially in the latter parts of the operation, when the resistance to farther impregnation becomes nearly a balance for the accumulating power of the magnets; and we consider this as no inconsiderable argument for the justice of Mr Æpinus's hypothesis.

The great advantage of this method is the regularity of the magnetism which it produces. We never find more than two poles; and when the bars are hard, and of uniform texture, the polarity is very little diffused, and seemingly confined to a very small space at the very extremities of the bar. This is indeed a prodigious advantage in point of strength. It is no less so in order to fit the magnets for experiments on the law of magnetic action; for the latitude which the diffused condition of the poles gives in the selection of the points from which the distances are to be computed, has hitherto hindered us from pronouncing on the law of magnetic action with the precision of which we think it fully susceptible. This method also is the only one by which we have been able to impregnate two bars joined end to end, considering them as one bar. We have sometimes (though very rarely) succeeded in this; so that when filings were strewed over them, the appearance could not be distinguished from a single bar.—*N. B.* Yet even in this case, in one experiment with two bars of six inches long, treated as one, when it could not be distinguished, either by the appearance of the filings, or by going round it very near with a compass needle, a very small compass needle discovered a neutral point, and a reversion of polarity similar to fig. 14. at F, shewing that it was really acting as two bars. Perhaps it must always be so; and this question is of considerable importance in the establishment of any theory of the internal process.

It deserves remark, that, in order to succeed in this attempt, a very considerable pressure is necessary. We were obliged to clean the ends of the bars very carefully, and to force the frame of bars and soft pieces of iron strongly together by wedges, in the manner of a form of types. We thought that wetting the ends of the bars with pure water aided the experiment; and we are *very certain* that oil not only greatly obstructed it, but even sensibly impeded the common process. We had put a single drop of oil on a pair of bars which we were touching in the common Cantonian method, that the magnets might be more easily drawn along them; but we were surprised at finding that we could not give a strong impregnation. The oil undoubtedly prevents the close contact. We found the finest gold leaf produce the same effect in a great degree; as also talc, of which a square inch weighed $\frac{1}{13}$th of a grain. We do not infer any thing like obstruction to the passage of something material, but rather ascribe it to mere distance; although we are of opinion, that in the impregnation of two contiguous bars, so that the magnetism (whatever it is) is disposed *precisely* as in one bar, there *is* a material transference. But we shall speak of this in its due place.

It is not unworthy of remark, that we found bars to acquire more powerful magnetism when pretty well polished than when rough. But we also found, that bars considerably rough acquired the first degrees of it much more expeditiously than those which are smooth; although we never could bring them to that high degree of magnetism that the same bars acquired after they had been polished. We think it probable, that the tremors, occasioned by the rough and harsh surfaces of the hard steel, are the causes of this phenomenon.

Some more observations on this method of the double touch will be made afterwards, when we consider the hypothesis of Mr Æpinus: and we conclude the present subject, by attempting to explain some puzzling appearances which frequently occur in making artificial magnets.

A bar touched by a very strong magnet has been said by Muschenbroek to be impaired by going over it with a weaker magnet. If it had been made as strong

Difficulties explained.

as possible, the weaker magnet, when passed over it in the way practised by Muschenbrock, must *first* destroy part of this magnetism; and having done so, it is unable to raise it anew to the same degree of vigour.

Yet (says Muschenbrock with surprise) a large bar of common iron has greatly improved the magnet. A very large piece of iron *must* do this (especially if shaped like a horseshoe, and applied with both heels), if the bar be not already at its maximum.

It was thought wonderful, that, in the method of double touch, not only was the magnetism of the magnets employed not impaired, but, beginning with two magnets, whose power is almost insensible, and repeating the operations in the precise manner described by Mitchell or Canton, not only the bars intended to be made magnetical, but also the magnets employed, may be brought to their highest possible state of magnetism. This is in evident conformity to the general facts of induced magnetism, and affords the strongest proof that nothing is communicated in this operation, but that powers residing in the bars are excited, or brought into action. The manipulation merely *gives occasion* to this action, as a spark of fire kindles a city.

There still remain some circumstances of this method, as practised by Savery, Canton, and Antheaume, which are extremely curious and important.

Mr Savery had observed a small bit of steel acquire very sensible magnetism by lying long in contact with the lower end of a great window bar. Telling this to a friend, he was, for the first time, informed, that this had been long observed, and that Dr Gilbert had made some curious inferences from it. Mr Savery wanted some magnets, and was at a distance from town. Reflecting, like a philosopher, on what he had heard, and observed, he saw here a source of magnetism which he could increase, in the manner commonly practised in making magnets. He placed the bar AB (fig. 21.) to be magnetised between two great bars of common iron C and D, placing all the three in the magnetical direction. He took another bar EF, and put two little pieces of iron, like the armour of a loadstone, on its ends; and with those ends he rubbed the bar AB, rubbing the upper half of it with the end F, and the lower with the end E. The result of this was a very brisk magnetism in a few minutes, which, by various well devised alternations, he brought to its highest degree. His numerous experiments published in the Philosophical Transactions in 1746, contain much curious information, highly deserving the attention of the philosophers. Mr Canton, proceeding on the same principle, that bars of iron, which have been long in a vertical position, acquire an efficient magnetism, begins his operations by placing his steel bar on the head of a kitchen poker, and rubs it with the lower end of a pair of kitchen tongs. Mr Antheaume adheres more strictly to the inferences from the principle of terrestrial magnetism, and repeats precisely the previous disposition of things practised by Mr Savery, placing his little steel bar AB (fig. 22.) between two great bars C and D of common iron, and arranging the whole in the magnetic direction. Then, proceeding most judiciously on the same principle, he greatly improves the process, by employing two bars EF and GH for the touch, holding them about an inch apart, inclined about 15° to the bar AB. It is plain, that the lower end of each of these five bars is a north pole, and the upper end a south pole. Therefore the poles F and G concur in giving the proper magnetism to the portion FG of the steel bar which is between them; and by rubbing it with these poles up and down, overpassing each extremity about half an inch, he must soon give to the bar AB a regular magnetism; weak, perhaps, but to be afterwards increased in the Cantonian method, on a horizontal table. In this manner did Mr Antheaume make magnets of very great strength in 1766. See his *Dissertation* already quoted.

These observations naturally bring us to the PHYSIOLOGIA NOVA DE MAGNETE ET CORPORIBUS MAGNETICIS of Dr Gilbert; a discovery which the sagacious Kepler classes among the greatest in the annals of science. 62 Gilbert terrestl magnet

It could not be that a phenomenon so general, and so interesting and important as the natural polarity of magnetic bodies, would be long known without exciting curiosity about its cause. Accordingly the philosophers of the 16th century speculated much about it, and entertained a variety of opinion, if that can be called an opinion which can hardly be said to express a thought. We have in *Marsigli Ficino* a short notice of many of these opinions. Some maintained that the needle was directed by a certain point in the heavens, as if that were saying more than that it always pointed one way. Others, with more appearance of reasoning, ascribed the direction to vast magnetic rocks. But all this was without giving themselves the trouble of trying to ascertain what situation of such rocks would produce the direction that is observed. Fracastori was, if we mistake not, the first who thought this trouble at all necessary; and he observes very sensibly, that if those rocks are supposed to be in any place yet visited by navigators, and if they act as loadstones do (a circumstance which he says must be admitted, if we attempt to explain), the direction of the needle will be very different from what we know it to be. He therefore places them in the inaccessible polar regions, but not in the very pole. Norman, the discoverer of the dip of the mariner's needle, or of the true magnetic direction, was naturally led by his discovery to conceive the directing cause as placed in the earth; because the north point of the needle, in every part of Europe, points very far below the horizon. But although he calls the treatise in which he announces his discovery the *New Attractive*, he does not express himself as supposing the needle to be attracted by any point within the earth, but only that it is always directed to that point.

It is to Dr Gilbert of Colchester that we owe the opinion now universally admitted, that magnetic polarity is a part of the constitution of this globe. Norman had, not long before, discovered, that if a steel needle be very exactly balanced on a horizontal axis, like the beam of a common balance, so that it would retain any position given it, and if it be then touched with a magnet, and placed on its axis in the magnetic meridian, it is no longer in equilibrio, but (at London) the north point of it will dip 72 or 73 degrees below the horizon. He did not, however, publish his discovery till he had obtained information how it stood in other parts of the world. The differences in the variation in different places naturally suggested the necessity of this to him. Being a maker of mariners compasses,

passes, and teacher of navigation in London, he had the fairest opportunities that could be desired, by furnishing dipping needles to such of the navigators, his scholars, as he knew most able to give him good information. And the accounts which he received made his discovery, when announced to the world, a very complete thing; for the commanders of ships engaged in long voyages, and particularly to China, informed him that, in the vicinity of the equator, his dipping needles remained parallel to the horizon, but that in coming toward the north pole, the north end of the needle was depressed, and that the south end dipped in like manner at the Cape of Good Hope, and in the Indian Ocean; that the needle gradually approached the horizontal position as the ship approached the equator, but that in coming to the north of it at Batavia, the north point again dipped, and at Canton was several degrees below the horizon.

On these authorities, Norman boldly said that, in the equatoreal regions, the needle was horizontal, and that either end dipped regularly as it approached either pole; and that in the poles of the earth, the needle was perpendicular to the horizon. He therefore announced this as a discovery, not only singularly curious, but also of immense importance; for by means of a dipping needle the latitude of a ship at sea may be found without seeing the sun or stars.

Dr Gilbert, comparing this position of the compass needle with the positions which he had observed small needles assume in his numerous experiments in relation to a magnet, as we have described at great length, was naturally led to the notion of the earth's being a great loadstone, or as containing one, and that this arranged the dipping, or, in general, the mariner's needle in the same manner as he observed a great magnet arrange a small needle poised on its pivot. He therefore composed his *Physiologia Nova de Magnete, et de Tellure magno Magnete*; in which he notices so many points of resemblance to the directive power of a magnet, that the point seems no longer to admit of any doubt. Dr Gilbert's theory may be thus expressed:

All the phenomena of natural magnetism are analogous to what we should observe, if the earth were a great magnet, having its poles near the poles of the earth's equator, the north pole not far from Baffin's Bay, and the south pole nearly in the opposite part of the globe. A dipping needle, under the influence of this great magnet, must arrange itself in a plane which passes through the poles of the magnet, the position of which plane is indicated (at least nearly) by the ordinary compass needle; and it will be inclined to the horizon so much the more as we recede from the equator of the great magnet.

This opinion of Dr Gilbert was not less ingenious than important; and if firmly established, it furnishes a complete theory of all the phenomena of magnetism. But observations were neither sufficiently numerous in the time of Dr Gilbert, nor sufficiently accurate, to enable that great genius to assign the position of this great magnet, nor the laws of its action. The theory was chiefly founded on the phenomena of the dipping needle; phenomena which might have been unknown for ages, had the first notice of them fallen into any other hands than Norman's. They are not, like those of variation, which might be made by any sailor. They require for their exhibition a dipping needle, and the attention to circumstances which can occur only to a mathematician. A dipping needle is to this day, notwithstanding all our improvements in the arts, one of the most delicate and difficult tasks that an instrument maker can take in hand, and a good one cannot be had for less than twenty guineas. We are confident that such as even Norman could make were far inferior to what are now made, and quite unfit for use at sea while the ship is under sail, although they may be tolerably exact for an observation of the dip in any port; and we presume that it was such observations only that Norman confided in. Our readers will readily conceive the difficulty of poising a needle with such a perfect coincidence of its centre of gravity and axis of motion, and perfect roundness of this axis, that it shall remain in any position that is given it. Add to this, that a grain of dust, invisible to the nicest eye, getting under one side of this axis, may be sufficient for making it assume another position. It must also be a difficult matter to preserve this delicate thing, so as that no change can happen to it. Besides, all this must be performed on a piece of tempered steel which we are certain has no magnetism. Where can this be got, or what can insure us against magnetism? Nor is there less difficulty in making the observations without great risk of error. If the needle, moveable only in a vertical plane, be not set in the plane of a magnetic meridian, it will always dip too much. At London, where the magnetic direction is inclined 73° to the horizon, if it be in a plane 20° from the magnetic meridian, it will stand almost perpendicular; for it is easy to see, by the mechanical resolution of forces, that it will take the position which brings it nearest to the true magnetic direction. This, we think, is confirmed by several of Norman's and other old observations of dip. They are much greater than they have been since found in the same places.

Mr Daniel Bernoulli has given a very ingenious principle, by which we can make a dipping needle which will give a very accurate observation on shore; and being so easily executed, it deserves to be generally known. Let a dipping needle be made in the best manner that can be done by a workman of the place, and balanced with some care before impregnation, so that we may be certain that when touched it will take nearly the true dip. Touch it, and observe the dip. Destroy its magnetism, and then alter its balance in such a manner that, without any magnetism, it will arrange itself in the inclination of the observed dip. Now touch it again, giving it the same poles as before. It is plain that it will now approach exceedingly near indeed to the true dip, because its want of *perfect* equilibrium deranged it but a few degrees from the proper direction. If this second observation of the dip should differ several degrees from the first, by the inaccurate first formation of the needle, it will be proper to repeat the operation. Very rarely indeed will the third observation of the dip vary from the truth half a degree. Daniel Bernoulli's dipping needle.

Mr Bernoulli makes this simple contrivance answer the purpose of an universal instrument in the following ingenious manner. A very light brass graduated circle EFG (fig. 23.) is fixed to one side of the needle, concentric with its axis, and the whole is balanced as nicely as possible before impregnation. A very light index

CD is then fitted on the axis, ſo as to turn rather ſtiffly on it. This will deſtroy the equilibrium of the needle. If the needle has been made with perfect accuracy, and perfectly balanced, the addition of this index would cauſe it always to ſettle with the index perpendicular to the horizon, whatever degree of the circle it may chance to point at. But as this is ſcarcely to be expected, ſet the index at various degrees of the circle, and note what inclination the unmagnetic needle takes for each place of the index, and record them all in a table. Suppoſe, for example, that when the index is at 50, the needle inclines 46° from the horizon. If in any place we obſerve that the needle (rendered magnetic by lying between two ſtrong magnets), having the index at 50, inclines 46°, we may be certain that this is the dip at that place; for the needle is not deranged by the magnetiſm from the poſition which gravity alone would give it. As we generally know ſomething of the dip that is to be expected in any place, we muſt ſet the index accordingly. If the needle does not ſhew the expected dip, alter the poſition of the index, and again obſerve the dip. See whether this ſecond poſition of the index and this dip form a pair which is in the table. If they do, we have got the true dip. If not, we muſt try another poſition of the index. Noticing whether the agreement of this laſt pair be greater or leſs than that of the former pair, we learn whether to change the poſition of the index in the ſame direction as before, or in the oppoſite. The writer of this article has a dipping needle of this kind, made by a perſon totally unacquainted with the making of philoſophical inſtruments. It has been uſed at Leith, at Cronſtadt in Ruſſia, at Scarborough, and at New York, and the dip indicated by it did not in any ſingle trial differ 1½ degrees from other trials, or from the dip obſerved by the fineſt inſtruments. He tried it himſelf in Leith Roads, in a rough ſea; and does not think it inferior, either in certainty or diſpatch, to a needle of the moſt elaborate conſtruction. It is worthy of its moſt ingenious author, and of the public notice, becauſe it can be made for a moderate expence, and therefore may be the means of multiplying the obſervations of the dip, which are of immenſe conſequence in the theory of magnetiſm, and for giving us an accurate knowledge of the magnetical conſtitution of this globe.

Opinion reſpecting the great magnet contained in this globe.

This knowledge is ſtill very imperfect, owing to the want of a very numerous collection of obſervations of the dip. They are of more importance than thoſe of the horizontal deviations from the meridian. All that we can ſay is, that the earth acts on the mariner's needle as a great loadſtone would do. But we do not think that the appearances reſemble the effects of what we would call a good loadſtone, having the regular magnetiſm of two vigorous poles. The dips of the needle in various parts of the earth ſeem to be ſuch as would reſult from the action of an extremely irregular loadſtone, having its poles exceedingly diffuſed. The increaſe of the dip, as we recede from thoſe places where the needle is horizontal, is too rapid to agree with the ſuppoſition of two poles of conſtipated magnetiſm, whether we ſuppoſe the magnetic action in the inverſe ſimple or duplicate ratio of the diſtances, unleſs the great terreſtrial magnet be of much ſmaller dimenſions than what ſome other appearances oblige us to ſuppoſe. If there be four poles, as Dr Halley imagined, it will be next to impoſſible to aſcertain the poſitions of the dipping needle. It will be a tangent to one of the ſecondary magnetic curves, and theſe will be of a species. We cannot but conſider the diſcovery of the magnetic conſtitution of this globe as a point of very great importance, both to the philoſopher and to ſociety. We have conſidered it with ſome care; but hitherto we have not been able to form a ſyſtematic view of the appearances which gives us any ſatiſfaction. The well informed reader is ſenſible, that the attempt by means of the horizontal or variation needle is extremely tedious in its application, and is very unlikely to ſucceed; at the ſame time it muſt be well underſtood. The two diſſertations by Euler, in the 13th and 22d volumes of the Memoirs of the Royal Academy at Berlin, are moſt excellent performances, and give a true notion of the difficulty of the ſubject. Yet, even in theſe, a circumſtance is overlooked, which, for any thing we know to the contrary, may have a very great effect. If the magnetic axis be far removed from the axis of revolution, as far, for example, as Mr Churchman places it, the magnetic meridians will be (generally) much inclined to the horizon; and we ſhall err very far, if we ſuppoſe (as in Euler's calculus) that the dipping needle will arrange itſelf in the vertical plane, paſſing through the direction of the horizontal or variation needle; or if we imagine that the poles of the great magnet are in that plane. We even preſume to think that Mr Euler's aſſumption of the place of his fictitious poles (namely, where the needle is vertical), in order to obtain a manageable calculus, is erroneous. The introduction of this circumſtance of inclination of the magnetic meridians to the horizon, complicates the calculation to ſuch a degree as to make it almoſt unmanageable, except in ſome ſelected ſituations. Fortunately, they are important ones for aſcertaining the places of the poles. But the inveſtigation by the poſitions of the dipping needle is incomparably more ſimple, and more likely to give us a knowledge of a multiplicity of poles. The conſideration of the magnetic curves (in the ſenſe uſed in the preſent article), teaches us that we are not to imagine the poles immediately under thoſe parts of the ſurface where the needle ſtands perpendicular to the horizon, nor the magnetic equator to be in thoſe places where the needle is horizontal; a notion commonly and plauſibly entertained. Unfortunately our moſt numerous obſervations of the dip are not in places where they are the moſt inſtructive. A ſeries ſhould be obtained, extending from New Zealand northward, acroſs the Pacific Ocean to Cape Fairweather on the weſt coaſt of North America, and continued through that part of the continent. Another ſeries ſhould extend from the Cape of Good Hope, up along the weſt coaſt of Africa to the tropic of Capricorn; from thence acroſs the interior of Africa (where it would be of great importance to mark the place of its horizontality) through Sicily, Italy, Dalmatia, the eaſt of Germany, the Gulph of Bothnia, Lapland, and the weſt point of Greenland. This would be nearly a plane paſſing through the probable ſituations of the poles. Another ſeries ſhould be made at right angles to this, forming a ſmall circle, croſſing the other near Cape Fairweather. This would paſs near Japan, through Borneo, and the weſt end of New Holland; alſo near Mexico, and a few degrees weſt of Eaſter Iſland. In this place, and at Borneo, the

See VARIATION, Encycl.

the inclination of the magnetic plane to the horizon would be conſiderable, but we cannot find this out. It may, however, be diſcovered in other points of this circle, where the dip is conſiderable. We have not room in this ſhort account to illuſtrate the advantages derived from theſe ſeries; but the reflecting reader will be very ſenſible of them, if he only ſuppoſes the great magnet to be accompanied by its magnetic curves, to which the needle is always a tangent. He will then ſee that the firſt ſeries from New Zealand to Cape Fairweather, and the ſecond from Cape Fairweather round the other ſide of the globe, being in one plane, and at very different diſtances from the magnetic axis, muſt contain very inſtructive poſitions of the needle. But we ſtill confeſs, that when we compare the dips already known with the variations, they appear ſo irreconcileable with the reſults of an uniform regular magnetiſm, that we deſpair of ſucceſs. Every thing ſeems to indicate a multiplicity of poles, or, what is ſtill more adverſe to all calculation, an irregular magnetiſm with very diffuſed polarity.

Much inſtruction may ſurely be expected from the obſervations of the Ruſſian academicians and their eleves, who are employed in ſurveying that vaſt empire; yet we do not meet with a ſingle obſervation of the dip of the needle in all the bygone publications of that academy, nor indeed are there many of the variation.

65 ...d concerning the ...ation of poles. For want of ſuch information, philoſophers are extremely divided in their opinions of the ſituation of the magnetic poles of this globe. Profeſſor Krafft, in the 17th volume of the Peterſburgh Commentaries, places the north pole in lat. 79° N. and long. 23° W. from London; and the ſouth pole in lat. 50° S. and long. 92° E.

Wilcke of Stockholm, in his indication chart (*Swed. Mem.* tom. xxx. p. 218.), places the north pole in N. Lat. 75°, near Baffin's Bay, in the longitude of California. The ſouth pole is in the Pacific Ocean, in lat. 70° S.

Churchman places the north pole in lat. 59° N. and long. 135° W. a little way inland from Cape Fairweather; and the ſouth pole in lat. 59° S. Long. 165° E. due ſouth from New Zealand.

A planiſphere by the Academy of Sciences at Paris for 1786, places the magnetic equator ſo as to interſect the earth's equator in long. 75°, and 155° from Ferro Canary Iſland, with an inclination of 12 degrees nearly, making it a great circle very nearly. But we are not informed on what authority this is done; and it does not accord with many obſervations of the dip which we have collected from the voyages of ſeveral Britiſh navigators, and from ſome voyages between Stockholm and Canton. Mr Churchman has given a ſketch of a planiſphere with lines, which may be called parallels of the dip. Thoſe parts of each parallel that have been aſcertained by obſervation are marked by dots, ſo that we can judge of his authority for the whole conſtruction. It is but a ſketch, but gives more ſynoptical information than any thing yet publiſhed. The magnetic equator cuts the earth's equator in long. 15°, and 195° E. from Greenwich, in an angle of nearly 17 degrees. The circles of magnetic inclination are not parallel, being conſiderably nearer to each other on the ſhort meridian than on its oppoſite. This circumſtance, being founded on obſervation, is one of the ſtrongeſt arguments for the exiſtence of a magnet of tolerable regularity, as the cauſe of all the poſition of the compaſs needle; for ſuch *muſt* be the poſitions of the circles of equal dip, if the axis of this magnet is far removed from the axis of rotation, and does not interſect it.

Now, if the ſituation of the poles be any thing near the average or medium of theſe determinations, and if we form all our notions by analogy, comparing the poſitions of the compaſs needle in relation to the great terreſtrial magnet, with the poſitions aſſumed by a ſmall needle in the neighbourhood of a magnet, we muſt conclude, that the magnetical conſtitution of this globe has little or no reference to its regular external form. The axis of the magnet is very far removed from that of the globe (at leaſt 1500 miles), and is not nearly parallel to it, nor in the ſame plane. It required the ſagacity and the ſkill of a Euler to ſubject ſuch anomalous magnetiſm to any rules of computation; and every perſon qualified to judge of the ſubject muſt allow his diſſertation in the 13th volume of the Berlin Memoirs to be a work of wonderful reſearch. It is a very agreeable thing to ſee ſuch a conformity between the lines which expreſs the regular magnetiſm of Euler's diſſertation, and the lines drawn by Dr Halley from obſervation, and which appeared to himſelf ſo capricious, that he deſpaired (notwithſtanding his conſummate ſkill in geometry) of their ever being reduced to a mathematical and preciſe ſyſtem. 66.

Without detracting from the merit of Dr Gilbert, we may preſume to ſay that his notion of the earth's being a great magnet was not, in his mind, more than a ſagacious conjecture, formed from a very general and even vague compariſon. Yet the compariſon was ſufficiently good to give him great confidence in his opinion that the action of this great magnet, in perfect conformity to what we obſerve in our experiments with magnets, is the ſource of all the magnetiſm that we obſerve. If there was nothing elſe in proof of the juſtneſs of his theory, it is abundantly proved by the beautiful experiment of Mr Henſhaw, mentioned in the article VARIATION, *Encycl.* p. 621. col. 2. An iron bar held nearly upright, attracts the ſouth end of a compaſs needle with its lower end; and if that end of the bar be kept in its place, and the bar turned round till it becomes the upper end, the ſouth point of the needle immediately turns away from it, and the north end is now attracted. This experiment may be perfectly imitated with artificial magnetiſm. 67 Confirmations of Dr Gilbert's phyſiology.

Having ſupported a large magnet SAN (fig. 24.), ſo that its ends are detached from ſurrounding bodies, place a ſmall needle B (poiſed on its pivot) about three inches below the north pole N of the magnet, and in ſuch a ſituation that its polarity to the magnet may be very weak. Take now a ſmall piece of common iron, and hold it in the poſition repreſented at C. Its lower end becomes a north pole, attracting the ſouth pole of the needle. Keeping this in its place, turn round the piece of iron into the poſition D; the ſouth pole of B will now avoid it, and the north pole will be attracted. We directed the needle to be ſo placed, that its polarity, in relation to the magnet, may be weak. If it be ſtrong, it may act on the end of C or D like a magnet, and counteract the magnetiſm induced on C or D by vicinity to A.

An anonymous writer in the Philosophical Transactions, No 177. Vol. XV. relates several observations made during a voyage to the East Indies, which are quite conformable to this. A few leagues northwest from the island Ascension, the south point of the compass needle hardly shewed any tendency to or from the lower end of an iron bar. It seemed rather to avoid the upper end; it was not in the least affected by the middle of the bar; but when the bar was laid horizontal, in the magnetic direction, its two ends affected the dissimilar ends of the compass needle very strongly; but when horizontal, and lying at right angles to the magnetic direction, its polarity was altogether indifferent.

As the other phenomena of induced artificial magnetism have the same resemblance to the phenomena of natural magnetism, a bar which has remained long in the vicinity of a magnet acquires magnetism (permanent) in the same way, and modified by the same circumstances, as in natural magnetism. Hammering a bit of common iron in the immediate vicinity of a magnet, gives it very good magnetism. Exposing a red hot bar to cool in the neighbourhood of a magnet has the same effect. Also quenching it suddenly has the same effect. Quenching a small red hot steel bar between two magnets, was found by us to communicate a much stronger magnetism than we could give it by any other method. Its form indeed was very unfavourable for the ordinary method of touching; for it consisted of two little spheres connected by a slender rod, and could scarcely be impregnated in any other way than by placing it for a very long while between magnets. In all these experiments, the polarity acquired is precisely similar to that acquired by the same treatment in relation to this supposed great terrestrial magnet. In short, in whatever manner we pursue this analogy in our experiments, we find the resemblance most perfect in the phenomena.

We cannot but think, therefore, that this new physiology of the magnet by Dr Gilbert is well established; and we think ourselves authorised to assume it as a proposition fully demonstrated, that the earth is a great magnet, or contains a great magnet, the agency of which produces the direction of the magnetic needle, and all the magnetism which iron acquires by long continuance in a proper position. It is this which made us say, in the beginning of this article, that attraction and polarity were not confined to magnets, but were properties belonging to all iron in its metallic state. We now see the reason why any piece of iron brought very near to another piece will attract it—both become magnetical, in consequence of the agency of the great magnet; and their magnetism is so disposed, that their mutual attractions exceed their repulsions. Also, why an iron rod, placed nearly in the magnetical direction, will finally arrange itself in that direction. Also, why the terrestrial polarity of common iron is indifferent, and either end of the rod will settle in the north, if it have nearly that position at first. The magnetism induced by mere momentary position is so feeble as to yield to any artificial magnetism. As a moment was sufficient for imparting it, a moment suffices for destroying it; and another moment will impart the opposite magnetism. But artificial magnetism requires more force for its production, and some of it remains when the producing cause is removed, and it does not yield at once to the contrary magnetism. That there is no farther difference appears from this, that long continued position gives determined and permanent magnetism, and that it is destroyed by an equally long continuance in the contrary position. It seems to be very generally true, that a magnet will carry more by its north than by its south pole. It should be so in this part of the world, because the terrestrial magnetism induced on the iron conspires with the magnetism induced by the north pole of a magnet, but counteracts the magnetism induced by the south pole.

The propriety of Mr Savery's, Mr Canton's, and Mr Antheaume's processes for beginning the impregnation of hard steel bars is now plain, and the superior effect of the two great bars of common iron in the proposed method of Mr Antheaume. We cannot but take this opportunity of paying the proper tribute of praise to the ingenuity of Mr Savery. Every circumstance of his process was selected in consequence of an accurate conception of magnetism, and the combination of this science with Dr Gilbert's theory. His process is the same with Antheaume's in every respect, except the circumstance of the double touch borrowed from Mitchell and Canton. These observations do not detract from the discernment of Mitchell and Canton, who saw in those experiments what had escaped the attention of hundreds of readers.

68 Seeming objection deduced from the want of sensible attraction.

But there occurs an objection to this theory of Dr Gilbert, which was urged against it with great force. We observe no tendency in the magnet or compass needle toward this supposed magnet. An iron or steel bar is not found to increase its tendency downwards, that is, is not sensibly heavier, when its south pole is uppermost in this part of the world. A needle set afloat on a piece of cork arranges itself quickly in the proper direction; but if continued ever so long afloat, it has never been observed to approach the north side of the vessel. This is quite unlike, what we observe in the mutual actions of magnets, or the action of magnets on iron. This objection appears to have given Dr Gilbert some concern; and he mentions many experiments which have been tried on purpose to discover some magnetical tendency. He gets rid of it as well as he can, by saying, that the directive power of a magnet extends much farther than its attractive power. He confirms this by several experiments. But Dr Gilbert had not studied the simultaneous actions of the four poles, nor explained, by the principles of compound motion, how these produced all the possible positions of the needle. Indeed, the composition of mechanical forces was by no means familiar with philosophers at the end of the 16th century. We see it now very distinctly. The polarity of the needle, or the force with which it turns itself into the magnetical position, depends on the difference between the *sums* of the actions of each pole of the magnet on both the poles of the needle; whereas its tendency towards the magnet depends on the difference of the *differences* of those actions (see n° 22, 25.) The first may thus be very great when the other is almost insensible. We see, that coarse iron filings heap about the magnet very fast, and that very fine filings approach it very slowly. Now, the largest magnet that we can employ, when compared with the great magnet in the earth, is but as a particle of the finest filings that can be conceived. This surely diminishes exceedingly, if it does not entirely annihilate the objection: but as we

have

have heard it urged by many as an improbable thing, that a long magnet, kept afloat for many months (which has been done) shall not shew the *smallest* tendency towards the pole of the terrestrial magnet, we think it deserves to be considered with accuracy, and the question decided in a way which will admit of no doubt.

69 This completely answered. Let the very small magnet C (fig. 25.) be placed near a great magnet A, and then near a smaller magnet B, in such a manner that its polarity to both shall be the same; and then let us determine the proportion between the attractions of A and B for the small magnet C.

This will evidently depend on the law of magnetic action. For greater simplicity of investigation, we shall content ourselves with supposing the action to be inversely as the distance.

Let AN, = AS, $= a$; BN $= b$; C$n = c$, AC $= d$, BC $= \delta$; and let the absolute force of A be to that of B at the same distance as m to 1.

The magnetic action being supposed proportional to $\frac{1}{d}$, we have,

1. Action of AN on C$s = \frac{m}{d-a-c}$.

2. ——— AN on C$n = -\frac{m}{d-a+c}$.

3. ——— AS on C$s = -\frac{m}{d+a-c}$.

4. ——— AS on C$n = \frac{m}{d+a+c}$.

5. The whole action $= \frac{8macd}{\overline{d^2-\overline{a+c}|^2} \times \overline{d^2-\overline{a-c}|^2}}$.

6. If c be very small in comparison with a or b, the whole action of A is very nearly $= \frac{8macd}{\overline{d^2-a^2}|^2}$.

7. And the tendency of C to B is, in like manner, $= \frac{8bc\delta}{\overline{\delta^2-b^2}|^2}$.

The directive powers of A and B are at their maximum state when C is placed with its axis at right angles to the lines AC or BC. In which case we have,

8. The directive power of A $= \frac{4ma}{d^2-a^2}$.

9. The directive power of B $= \frac{4b}{\delta^2-b^2}$.

When these directive powers are made equal, by placing C at the proper distances from A and B, we have,

10. $4ma : 4b$, or $ma : b = d^2-a^2 : \delta^2-b^2$
And $ma\delta^2 - mab^2 = bd^2 - ba^2$
$ma\delta^2 = b(d^2-a^2) + mab^2$.

11. $\delta^2 = \frac{b}{ma}(d^2-a^2) + b^2$.

12. $\delta = \sqrt{\frac{b}{ma}(d^2-a^2) + b^2}$.

Let the attractions of A and B for the very small magnet C, when its polarity to both is the same, be expressed by the symbols α and β. We have

$\alpha : \beta = \frac{8macd}{(d^2-a^2)^2} : \frac{8bc\delta}{(\delta^2-b^2)^2}$, which, by n° 10. is $= \frac{8(d^2-a^2)cd}{(d^2-a^2)^2} : \frac{8(\delta^2-b^2)c\delta}{(\delta^2-b^2)^2} = \frac{d}{d^2-a^2} : \frac{\delta}{\delta^2-b^2}$ $= bd : ma\delta$; that is,

13. Attr^n of A : attr^n of B $= bd : ma\delta$.

As an example of this comparison, let us suppose the great terrestrial magnet to be a thousand times larger and stronger than the magnet whose attraction we are comparing with that of terrestrial magnetism. Let us also suppose the distance from the pole of the great magnet to be small, so that its attraction may be considerable. Let us make $d = 1200$, a being $= 1000$, and $b = 1$. These are all very reasonable suppositions. Substituting these values in the formula, we have attr^n of A : attr^n of B $= 1 : 1000$ very nearly; and therefore when the needle, when placed near a magnet, vibrates by its polarity as fast as it does by natural magnetism, its tendency toward that magnet must be altogether insensible; for the disproportion is incomparably greater than that of 1 to 1000, in the largest magnets with which we can make experiments. Observe also, that we have taken the case where the attractions are the strongest, viz. when the magnet C is placed in the axis of A or B. In the oblique positions, tangents to the magnetic curves, the attractions are smaller, almost in any ratio.

We took the inverse ratio of the distances for the law of action, only because the analysis was very simple. It is very evident, that the disproportion will be still more remarkable if the action be inversely as the square of the distance.

The objection therefore to the origin of the polarity of the compass needle, and of all other magnets, namely, the action of a great magnet contained in the earth, appears plainly to be of no force. We rather think that the want of all sensible attraction, where there is a brisk polarity, is a proof of the justness of the conjecture; for if the compass needle were arranged by the action of magnetic rocks, or even extensive strata, near the surface of the earth, the attractions would bear a greater proportion to the polarities. We have even observed this. A considerable mass of magnetic stratum was found to derange the needle of a surveyor's theodolite at a considerable distance all around (about 140 yards). The writer placed the needle on a thin lath, which just floated it on water in a large wooden dish, and set it in a place where it was drawn about 15 degrees from the magnetic meridian. It was left in that situation a whole night, well defended from the wind by a board laid on the dish. Next morning it was found applied to that side of the dish which was nearest to the disturbing rocks. It had moved about six inches. This was repeated three times, and each time it moved in the same direction (nearly), which differed considerably from the direction of the needle itself.

It is now plain that we may, with confidence, assume Dr Gilbert's theory of terrestrial magnetism as sufficiently established. And, since we must certainly call that the north pole of the great magnet which is situated in the northern parts of the earth, and since those poles of magnets which attract each other have opposite polarities, we must say, that what we call the north pole of a mariner's needle, or of any other magnet, has the southern polarity.

We may now venture to go farther with Dr Gilbert, and

70
The great magnet is the source of all natural magnetism.

and to say that all the magnetism which we observe, whether in nature or art, is either the immediate or the remote effect of the action of the great magnet. As soft bars soon acquire a transient magnetism, as hard bars, after long exposure, acquire a sensible and permanent magnetism—we must infer, that ores of iron, which are in a state fit for impregnation, must acquire a sensible and permanent magnetism by continuing, for a series of ages, in the bowels of the earth. And thus the magnetism of loadstones, which, till the discovery of the natural magnetism acquired by position, were the sources of all our magnetical phenomena, is now proved to be a necessary consequence of the existence and agency of a great magnet contained in the bowels of the earth.

71
Loadstones in the mine may have their poles in any position.

It seems to result from this theory, that, in these northern parts of the world, that part of every natural loadstone that is at the extremity of the line drawn through the stone in the magnetic direction should be its pole; and that the loadstone, when properly poised, should of itself assume the very position which it had in the mine. Dr Gilbert complains of the inattention of miners (*rude hominum genus, lucro potius quam physicæ consulentes*) to this important circumstance. Once, however, he had the good fortune to be advertised of a great magnetic mass lying in its matrix. He repaired quickly to the mine, examined it, and marked its points which were in the extremities of the magnetic line. When it was detached from its matrix, he had the pleasure of finding its poles in the very places he expected. The loadstone was of considerable size, weighing about 20 pounds.—Mr Wilcke gives in the Swedish Commentaries several instances of the same kind.

But should this always be the case? By no means. There are many circumstances which may give the magnetism of a loadstone a very different direction. We have found, that simple juxtaposition to a magnet will sometimes give a succession of poles to a long bar of hard steel. The same thing may happen to an extensive vein of magnetisable matter. The loadstone taken out of this vein may have been placed like that of a soft bar placed in the magnetic line, if lying in one part of the vein; if taken from another part of it, its polarity may be the very reverse; and in another part it may have no magnetism, although completely fitted for acquiring it. It may have its poles placed in a direction different from all these, in consequence of the vicinity of a greater loadstone. As loadstones possessed of vigorous magnetism are always found only in small pieces, and in pieces of various sizes and force, we must expect every position of their poles. The only thing that we can expect by theory is, that adjoining loadstones will have their friendly poles turned toward each other, and a general prevalence of or tendency to a polarity symmetrical with that of the earth. The reader will find some more observations to this purpose in the article VARIATION, *Encycl.* p. 623 as also in Gilbert's treatise, B. III. c. 2. p. 121.

Nor should all strata or masses of iron ore be magnetical. We know that none are susceptible of induced magnetism, but such as are, to a certain degree, in the metallic state. Such ores are not abundant. Nay, even all of such strata do not necessarily acquire magnetism by the action of the great magnet. If their principal dimensions lie nearly perpendicular to the magnetic direction, they will not acquire any sensible quantity. A stratum in this country, rising about 17 degrees to the N. N. W. will scarcely acquire magnetism. It may also happen, that the influence of the great magnet is counteracted by that of some extensive stratum inaccessible to man, by reason of its great depth.

72
Probable cause of their great natural vigour.

Thus we see, that all the appearances of the original magnetism of loadstones are perfectly consistent with the notion that they are effects of one general cosmical cause, the action of the great magnet contained in the earth, and that there is no occasion to suppose this great magnet to differ, in its constitution or manner of action, from the small masses of similar matter called loadstone. The only difficulty that presents itself is the great superiority of magnetic force observable in some loadstones over other masses of ores circumjacent, which are not distinguishable by us by any other circumstance. We acknowledge ourselves unable to solve this difficulty; for the magnetism of such pieces is sometimes incomparably stronger than what a bar of iron acquires by position; yet this bar is much more susceptible than the ores which are fit for becoming loadstones. Perhaps there is some chemical change which obtains gradually in certain masses, which aids the impregnation, in the same way that we know that being red hot destroys all magnetism, whether in a metal bar or in an ore. This seems to be confirmed by what we see in some old iron stanchions, which acquire the strongest magnetism in those parts of their substance which are combining themselves with ingredients floating in the atmosphere. That part which is cased in the stone, and exfoliates and splits with rust, being converted into something like what is called finery-cinder, becomes highly and permanently magnetic. Such peculiarities as these, operating for ages, may allow a degree of magnetical impregnation (in whatever this may consist) to take place, to which we can see no resemblance in our experiments. It would be worth while to place iron wires in a tube in the magnetic direction, which could be kept of a proper red heat, while it is converted into æthiops by steam. It is not unlikely that it would acquire a sensible and permanent magnetism in this way. It may be, that the little atoms, as they arrange themselves in a sort of crystalline or symmetrical form, may also arrange so as to favour magnetism. Were this tried in the vicinity of a strong magnet, the effect might be more remarkable and precise. Perhaps, too, while iron is precipitated in a metallic form from its solutions by another metal, something of the same kind may happen. We know, that proper ores of iron, exposed to cementation in a low red heat, in the magnetic direction, becomes magnetic.

73
Natural causes of the changes of the magnetic direction.

Notice has been taken in the *Encycl.* art. VARIATION, of the attempts of ingenious men to explain the change which is observed in all parts of the globe, on the direction of the mariner's needle, the gradual change of the variation. The hypothesis of Dr Halley, that the globe which we inhabit is hollow, and incloses a magnetic nucleus, moving round another axis, is not inconsistent with any natural law, if he did not suppose the interval filled up with some fluid. The action of the nucleus and shell on the intervening fluid would gradually bring the two to one common motion of rotation, as may be inferred from the reasonings employed by Newton in his remarks on the Cartesian vortices.

Leaving

Leaving out this circumſtance, there is only another cauſe which can affect, and muſt affect, the rotation of both; namely, the mutual action of the magnetic nucleus, and the maſſes of magnetic matter in the ſhell. If the axis of rotation of this nucleus be different from the line joining its magnetic poles, theſe poles will have a motion relative to the ſhell; and this motion may eaſily be conceived ſuch as will produce the changes of magnetic direction which we obſerve. It may even produce a motion of the northern magnetic pole in one direction, and of the ſouthern pole in the oppoſite direction, and this with the appearance of different periods of rotation, as ſuppoſed by Mr Churchman. We may here obſerve, by the way, that the change of magnetic direction in this country is not nearly ſo great as is commonly imagined. The horizontal needle has ſhifted its poſition about 35° at London ſince 1585; but the point of the dipping needle has not changed 10°. We may alſo obſerve, that when the pole of the central magnet changes its place, the magnetiſm of an extenſive ſtratum, influenced by it, may ſo alter its diſpoſition, as to change the poſition of the compaſs needle in the oppoſite direction to that of the change which the central magnet alone would induce on it.

But as motions have not yet been aſſigned to this nucleus, which quadrate with the obſerved poſitions of the needle, and as the very exiſtence of it is hypothetical, it may not be amiſs to examine, whether ſuch a change of variation may not be explained by what we know of the laws of magnetiſm, and of the internal conſtitution of this earth?

1. It is pretty certain, that the veins in which loadſtones are found are not parts of the great magnet. This appears from their having two poles while in the mine, and alſo from the very ſmall depth to which man has been able to penetrate. When we compare the poſitions of the dipping needle with thoſe of a ſmall needle near a magnet, we muſt infer, that the poles are very far below the ſurface.

Yet we know, that there are magnetiſable ſtrata of very great extent occupying a very conſiderable portion of the external covering. Though their bulk and abſolute power may be ſmall, when compared with thoſe of the great magnet, yet their greater vicinity to the needles on which obſervations are made, may give them a very ſenſible influence. In this way may a great deal of the obſerved irregularities of the poſitions of the needle be accounted for. In the Lagoon at Teneriffe, *Feuillée* obſerved the variation 13° 30′ weſt in 1724, while at the head of the iſland it was only 5°. The dip at the Lagoon was 63° 30′, greatly ſurpaſſing what was obſerved in the neighbourhood. Muller found, in the mountains of Bohemia, great and deſultory differences of declination, amounting ſometimes to 50′. At Mantua, the variation in 1758 was 12°; while at Bononia and Brixia it was nearly 18°. Great irregularities were obſerved by Goëte in the Gulph of Finland, eſpecially near the iſland of Suſſari, among ſome rocks: on one of theſe, the needle ſhewed no polarity. Captain Cook and Captain Phipps obſerved differences of 10°, extending to a conſiderable diſtance, on the weſt coaſts of North America. In the neighbourhood of the iſland Elba in the Mediterranean, the poſition of the needle is greatly affected by the iron ſtrata, in which that iſland ſo much abounds. In this country, there are alſo obſerved ſmall deviations which extend over conſiderable tracts of country, indicating a great extent of ſtrata that are weakly magnetic. Since ſuch ſtrata receive their magnetiſm by induction, in a manner ſimilar to a bar of hard ſteel, and ſince we know that this receives it gradually, it may very probably happen, that a long ſeries of years may elapſe before the magnetiſm attains its ultimate diſpoſition.

Here, then, is a neceſſary change of the magnetic direction; and although it may be very different in different places, according to the diſpoſition and the power of thoſe ſtrata, there muſt be a general vergency of it one way.

2. It is well known that all metals, and particularly iron, are in a progreſs of continual production and demetallization. The veins of metals, and more particularly thoſe of iron, are evidently of poſterior date to that of the rocks in which they are lodged. Chemiſtry teaches us, by the very nature of the ſubſtances which compoſe them, that they are in a ſtate of continual change. This is another cauſe of change in the magnetic direction. Nay, we know that ſome of them have ſuddenly changed their ſituation by earthquakes and volcanoes. Some of the ſtreams of lava from Veſuvius and Ætna abound in iron. This has greatly changed its ſituation; and if the ſtrata from which it proceeded were magnetical, the needle in its neighbourhood muſt be affected. Nay, ſubterranean heat alone will effect a change, by changing the magnetiſm of the ſtrata. Mr Lievog, royal aſtronomer at Beſſeſtedt in Iceland, writes, that the great eruption from Hecla in 1783, changed the direction of the needle nine degrees in the immediate neighbourhood. This change was produced at a mile's diſtance from the frozen lava; and it diminiſhed to two degrees at the diſtance of 2½ miles. He could not approach any nearer, on account of the heat ſtill remaining in the lava, after an interval of 14 months.

All theſe cauſes of change in the direction of the mariner's needle muſt be partial and irregular. But there is another cauſe, which is coſmical and univerſal. Dr Halley's ſuppoſition of four poles, or, at leaſt, the ſuppoſition of irregular and diffuſed poles, ſeems the only thing that will agree with the obſervations of declination. We know that all magnetiſm of this kind (that is, diſpoſed in this manner) has a natural tendency to change. The two northern poles may have the ſame or oppoſite polarities. If they are the ſame, their action on each other tends to diminiſh the general magnetiſm, and to cauſe the centre of effort to approach the centre of the magnet. If they have oppoſite polarities, the contrary effect will be produced. The general magnetiſm of each will increaſe, and the pole (or its centre of effort) will approach to the ſurface. In either of theſe caſes, the compound magnetiſm of the whole may change exceedingly, by a change by no means conſiderable in the magnetiſm of each pair of poles. It is difficult to ſubject this to calculation; but the reader may have very convincing proof of it, by taking a ſtrong and a weaker magnet of the ſame length, and one of them, at leaſt, of ſteel not harder than ſpring temper. Lay them acroſs each other like an acute letter X, and then place a compaſs needle, ſo that its plane of rotation may be perpendicular to the plane of the X. Note exactly the poſition in which the needle ſettles. In a few minutes after, it will be found to change conſiderably,

siderably, although no remarkable change has yet happened to the magnets themselves.

---

74 Speculations about the origin of magnetism. Hypothesis of Æpinus.

We flatter ourselves, that our readers will grant that the preceding pages contain what may justly be called a theory of magnetism, in as much as we have been able to include every phenomenon in one general fact, the induction of magnetism; and have given such a description of that fact and its modifications, that we can accurately predict what will be the appearances of magnets and iron put into any desired situation with respect to each other. If our notions of philosophical disquisition (delivered in art. PHILOSOPHY, *Encycl. Brit.*) be just, we have explained the subordinate phenomena, or have given a theory of magnetism.

But it is not easy to satisfy human curiosity. Men have even investigated, or sought for causes of the perseverance of matter in its present condition. We have not been contented with Newton's theory of the celestial motions, and have sought for the cause of that mutual tendency which he called gravitation, and of which all the motions are particular instances.

Philosophers have been no less inquisitive after what may be the cause of that mutual attraction of the dissimilar poles, and the repulsion of the similar poles, and that faculty of mutual impregnation, or excitement, which so remarkably distinguish iron, in its various states, from all other substances. The action of bodies on each other at a distance, has appeared to them an absurdity, and all have had recourse to some material intermedium. The phenomenon of the arrangement of iron filings is extremely curious, and naturally engages the attention. It is hardly possible to look at it without the thought arising in the mind of a stream issuing from one pole of the magnet, moving round it, entering by the other pole, and again issuing from the former outlet. Accordingly, this notion has been entertained from the earliest times, and different speculatists have had different ways of conceiving how this stream operated the effects which we observe.

The simplest and most obvious was just to make it act like any other stream of fluid matter, by impulsion. Impulsion is the thing aimed at by all the speculatists. They have a notion, that we conceive this way of communicating motion with intuitive clearness, and that a thing is fully explained when it can be shewn that it is a case of impulsion. We have considered the authority of these explanations in the article IMPULSION of this *Supplement*, and need not repeat our reasons for refusing it any pre eminence. But even when we have shewn the phenomena to be cases of impulsion by such a stream, the greatest difficulty, the most curious and the most embarrassing, is to ascertain the sources of this impulsive motion of the fluid—How, and from what cause does it begin? What forces bend it in curves round the magnet? Those philosophers, whose principle obliges them to explain gravitation also by impulse, must have another stream to impel this into its curves. Acting by impulsion, this magnetic stream must lose a quantity of motion equal to what it communicates. What is to restore this? What directs it in a particular course thro' the magnet? And what is it that can totally alter that course—in a moment—in all the phenomena of induced magnetism? How does it impel? Lucretius, either of himself, or speaking after the Greek philosophers, makes it impel, not the iron, but the surrounding air, sweeping it out of the way; and thus giving occasion for the surrounding air to rush around the magnet, and to hurry the bits of iron toward it. There is, perhaps, more ingenious refinement in this thought than in any of the impulsive theories adopted since his day by Des Cartes, Euler, and other great philosophers: But it is sagaciously remarked by D. Gregory, in his MS. notes on Newton, that this theory of Lucretius falls to the ground; because the experiments succeed just as well under water as in the air. As to the explanations, or descriptions, of the canals and their dock gates, opening in one direction, and shutting in the other, constructions that are changed in an instant in a bar of iron, by changing the position of the magnet, we only wonder that men, who have a reputation to lose, should ever hazard such crude and unmechanical dreams before the public eye. The mind of man cannot conceive the possibility of their formation; and if they are really formed, the effects should be the very opposite of those that are observed: the stream should move those bodies least which afford ready channels for its passage. If a rag of iron filings be arranged by the impulsion of such a stream, it should be carried along by it; and if it is *impelled toward* one end of the magnet, it should be impelled *from* the other end. Since we now know, that each particle of filings is a momentary magnet, we must allow a similar stream whirling round each. Is that an explanation which exceeds all power of conception?

But has it ever been shewn, that there is any impulsion at all in these phenomena? Where is the impelling substance? The only argument ever offered for its existence is, that we are resolved that the phenomena of magnetism shall be produced by impulsion, and the arrangement of iron filings looks somewhat like a stream. But enough of this. We trust that we have shewn the way in which this arrangement obtains in the clearest manner. Every particle becomes magnetic by induction. This is a fact, which sets all reasoning at defiance. The polarity of each rag is so disposed, that their adjoining ends turn to each other. This is another uncontrovertible fact. And these two facts explain the whole. The arrangement of iron filings, therefore, is a secondary fact, depending on principles more general; and therefore cannot, consistently with just logic, be assumed as the foundation of a theory.

Had magnetism exhibited no phenomena besides the attraction and repulsion of magnets, it is likely that we should not have proceeded very far in our theories, and would have contented ourselves with reducing these phenomena to their most general laws. But the communication of magnetism seems a great mystery. The simple approach of a magnet communicates these powers to a piece of iron; and this without any diminution of its own powers. On the contrary, beginning with magnets which have hardly any sensible power, we can, by a proper alternation of the manipulations, communicate the strongest magnetism to as many hard steel bars as we please; and the original magnets shall be brought to their highest degree of magnetism. We have no notion of powers or faculties, but as qualities of some substances in which they are inherent. Yet here is no appearance of something abstracted from one body, and communicated to, or shared with another. The process is like kindling a great fire by a simple spark; here

is no communication, but only *occasion* given to the exertion of powers inherent in the combustible matter. It appears probable, that the case is the same in magnetism; and that all that is performed in making a magnet is the excitement of powers already in the steel, or the giving occasion for their exertion; as burning the thread which ties together the two ends of a bow, allows it to unbend. This notion did not escape the sagacity of Dr Gilbert; and he is at much pains to shew, that the *coitio magnetica* is a quality inherent in all magnetical bodies, and only requires the proper circumstance for its exertion. He is not very fortunate in his attempts to explain *how* it is developed by the vicinity of a magnet, and how this faculty, or actual exertion of this power, becomes permanent in one body, while in another it requires the constant presence of the magnet.

74 It is to Mr Æpinus, of the Imperial Academy of St Petersburgh, that we are indebted for the first really philosophical attempt to explain all these mysteries. We mentioned, in the article Electricity, *Suppl.* the circumstance which suggested the first hint of this theory to Æpinus, *viz.* the resemblance between the attractions and repulsions of the tourmaline and of a magnet. A material cause of the electric phenomena had long been thought familiar to the philosophers. They had attributed them to a fluid which they called an electric fluid, and which they conceived to be shared among bodies in different proportions, and to be transferable from one to another. Dr Franklin's theory of the Leyden phial, which led him to think that the faculty of producing the electrical phenomena depended on the deficiency as well as the redundancy of this fluid, combined with the phenomena of induced electricity, suggested to Æpinus a very perspicuous method of stating the analogy of the tourmaline and the magnet; which he published in 1758 in a paper read to the academy.

Reflecting more deeply on these things, Mr Æpinus came by degrees to perceive the perfect similarity between all the phenomena of electricity by position and those of magnetism; and this led him to account for them in the same manner. As the phenomena of the Leyden phial, explained in Franklin's manner, shews that a body may appear electrical all over, by having less than its natural quantity of the electric fluid, as well as by having more, it seemed to follow, that it may also be so in respect to different parts of the same body; and therefore a body may become electrified in opposite ways at its two extremities, merely by abstracting the fluid from one end, and condensing it in the other; and thus may be explained the phenomena of induced electricity, where nothing appears to have been communicated from one body to the other. If this be the case, the two ends of a body rendered electric by induction should exhibit the same distinctions of phenomena that are exhibited by bodies wholly redundant and wholly deficient. The redundant ends should repel each other; so should the deficient ends; and a redundant part should attract a deficient. All these results of the conjecture tally exactly with observation, and give a high degree of probability to the conjecture. The similarity of these phenomena to the attractions of the dissimilar poles of a magnet, and the repulsions of the similar poles, is so striking, that the same mode of explanation forces itself on the mind, and led Mr Æpinus to think, that the faculty of producing the magnetical phenomena belonged to a magnetical fluid, residing in all bodies susceptible of magnetism; and that the exertion of this faculty require nothing but the abstraction of the fluid from one end of the magnetic bar, and its constipation in the other. And this conjecture was confirmed by observing, that in the induction of magnetism on a piece of iron, the power of the magnet is not diminished.

All these circumstances led Mr Æpinus to frame the following hypothesis:

1. There exists a substance in all magnetic bodies, which may be called the magnetic fluid; the particles of which repel each other with a force decreasing as the distance increases.

2. The particles of magnetic fluid attract, and are attracted by the particles of iron, with a force that varies according to the same law.

3. The particles of iron repel each other according to the same law.

4. The magnetic fluid moves, without any considerable obstruction, through the pores of iron and soft steel; but is more and more obstructed in its motion as the steel is tempered harder; and in hard tempered steel, and in the ores of iron, it is moved with the greatest difficulty.

In consequence of this supposed attraction for iron, the fluid may be contained in it in a certain determinate quantity. This quantity will be such, that the accumulated attraction of a particle for all the iron balances, or is equal to, the repulsion of all the fluid which the iron contains. The quantity of fluid competent to a particle of iron is supposed to be such, that the repulsion exerted between it and the fluid competent to another particle of iron is also equal to its attraction for that particle of iron: And therefore the attraction between the fluid in an iron bar A for the iron of another bar B, is just equal to its repulsion for the fluid in B; it is also equal to the repulsion of the iron in A for the iron in B. This quantity of fluid residing in the iron may be called its NATURAL QUANTITY.

In consequence of the mobility through the pores of the iron, the magnetic fluid may be abstracted from one end of a bar, and condensed in the other, by the agency of a proper external force. But this is a violent state. The mutual repulsion of the particles of condensed fluid, and the attraction of the iron which it has quitted, tend to produce a more uniform distribution. If we reflect on the law of action, we shall clearly perceive, that somewhat of this tendency must obtain in every state of condensation and rarefaction, and that there can be a perfect equilibrium only when the fluid is diffused with perfect uniformity. This, therefore, may be called the NATURAL STATE of the iron.

If the resistance opposed by the iron to the motion of the magnetic fluid be like that of perfect fluids to the motion of solid bodies, arising entirely from the communication of motion, there is no tendency to uniform diffusion so weak as not to overcome such resistance, and finally to produce this uniform distribution. But (as is more probable) if the obstruction resembles that of a clammy fluid, or of a soft plastic body like clay, some of the accumulation, produced by the agency of an external force, may remain when the force is removed; the diffusion will cease whenever the equalising force is just in equilibrio with the obstruction.

All the preceding circumstances of the hypothesis are

are so perfectly conformable to the hypothesis of Mr Æpinus for explaining the electrical phenomena, which is given in detail in the article Electricity of this *Supplement*, that it would be superfluous to enter into a minute discussion of their immediate results. We therefore beg the reader to peruse that part of the article Electricity where the elements of Æpinus's hypothesis are delivered, and the phenomena of induced electricity explained (see from n° 11. to 63. inclusive), and to suppose the discourse to relate to the *magnetical* fluid. Let N, S, *n*, *s*, be considered as the overcharged and undercharged parts of a magnetical body, or the poles of a magnet, and of iron rendered magnetical by induction. We shall confine our observations in this place to those circumstances in which the mechanical phenomena of magnetism are limited by the circumstance, that magnets always contain their natural quantity of fluid; so that their action on iron, and on each other, depends entirely on its unequable distribution; as is the case with induced electricity.

Magnetism induced on iron. Let the magnet NAS (fig. 26.), having its north pole NA overcharged, be set near to the bar *n* B *s* of common iron, and let their axes form one straight line. Then (as in the case of electrics) the overcharged pole NA acts on the bar B only by means of the redundant fluid which it contains. For that portion of its fluid, which is just sufficient for saturating the iron, will repel the fluid in B, just as much as the iron in NA attracts it; and therefore the fluid in B sustains no change from this portion of the fluid in NA. In like manner, the pole SA acts on B only in consequence of the iron in SA, which is not saturated or attended by its equivalent fluid.

If the fluid in B is immoveable, even the redundant fluid in NA, and redundant iron in SA, will produce no *sensible* effect on it: For every particle of iron in B is accompanied by as much fluid as will balance, by its repulsions and attractions, the attractions and repulsion of the coincidant particle of iron. But as the magnetical fluid in B is supposed to be easily moveable, it will be repelled by the redundant fluid in AN toward the remote extremity *n*, till the resistance that it meets with, joined to its own tendency to uniform diffusion, just balances the repulsion of AN. This tendency to uniform diffusion obtains as soon as any fluid quits its place; as has been sufficiently explained in the Supplementary article Electricity, n° 16. 17. &c.)

But, at the same time, the redundant iron in AS attracts the fluid in B, and would abstract it from B *n*, and condense it into B *s*. This attraction opposes the repulsion now mentioned. But, because AS is more remote from every point of B than AN is from the same point, the repulsions of the redundant fluid in AN will prevail; and, on the whole, fluid will be propelled toward *n*, and will be rarefied on the part B *s*. But as to what will be the law of distribution, both in the redundant and deficient parts of B, it is plain that nothing can be said with precision. This must depend on the distribution of the fluid in the magnet NAS. The more diffused that we suppose the redundant fluid and matter in the magnet, the farther removed will the centres of effort of its poles be from their extremities; the smaller will be the action of AN and AS, the smaller will be their difference of action; and therefore the smaller will be the condensation in B *n*, and the rarefaction in B *s*. Hence we learn, at the outset of this attempt to explanation, that the action of a magnet will be so much the greater as its poles are more concentrated. This is agreeable to observation, and gives some credit to the hypothesis. We can judge, in a very general manner, that the fluid will be rarer than its natural state in *s*, and denser in *n*; and that the change of density is gradual, and that the density may be represented by the ordinates of some line *c b d* (fig. 27.), while the natural density is represented by the ordinates to the line C *b* D, parallel to *s n*. There will be some point B of the iron bar, where the fluid will be of its natural density, and the ordinate B *b* will meet the line *c b d* in the point of its intersection with CD.

All this action is internal and imperceptible. Let us inquire what will be the *sensible* external action. There is a superiority of attraction towards the magnet: For since the magnetic action is supposed to diminish continually by an increase of distance, the curve, whose ordinates represent the forces, has its convexity toward the axis. Also, the force of the poles AN, AS are equal at equal distances: For, by the hypothesis, the attraction and repulsion of an individual particle are equal at equal distances; and the condensation in AN is equal to the deficiency in AS, by the same hypothesis; because NAS still contains its natural quantity of fluid. Therefore the action of both poles may be expressed by the ordinates of the same curve, and they will differ only by reason of their distances. We may therefore express the actions by the four ordinates M *m*, P *p*, N *n*, Q *q*, of fig. 2; of which the property (deduced from the single circumstance of its being convex toward the axis) is, that M *m* + Q *q* is greater than P *p* + N *n*. There is therefore a surplus of attraction. It is only this surplus that is perceived. The fluid, moveable in B, but retained by it so as not to be allowed to escape, is pressed towards its remote end *n*, by the excess P *p* — Q *q* of the repulsion of the redundant fluid in AN, above the attraction of the redundant iron in AS. This excess on every particle of the fluid is transmitted, by the common laws of hydrostatics, to the stratum immediately incumbent on the extremity *n*, and B is thus pressed away from A. But every particle of the solid matter in B is attracted towards A by the excess M *m* — N *n* of the attraction of the redundant fluid in AN above the repulsion of the redundant iron in AS: and this excess is greater than the other; for *m* + *q* is greater than *p* + *n*.

The piece of common iron *n* B *s* is therefore attracted, *in consequence* of the fluid in it having been propelled towards its remote extremity, and distributed in a manner somewhat resembling its distribution in NAS. Now, in this hypothesis, magnetism is held to depend entirely on the distribution of the fluid. B has therefore become a magnet, has magnetism induced on it, and, only in consequence of this induction, is attracted by A.

Had we supposed the deficient, or south pole of A, to have been nearest to B, the redundant matter in AN would have attracted the moveable fluid in B more than the remoter redundant fluid in AS repels it; and, on this account, the magnetic fluid would have been constipated in B *s*, and rarefied in B *n*. It would, in this case also, have been distributed in a manner similar to its

its situation in the magnet. And B would therefore have been a momentary magnet, having its redundant pole fronting the deficient or dissimilar pole of A. It is plain, that there would be the same surplus of attraction in this as in the former instance, and B would (on the whole) be attracted in consequence, and only in consequence, of having had a properly disposed magnetism induced on it by juxtaposition. The sensible attraction, in this case, is a *consequence* of the distribution now described; because, since the fluid constipated in the end next to A cannot quit B, the tendency of this fluid toward A must press the solid matter of B in this direction (by hydrostatical laws) more than this solid matter is repelled in the opposite direction.

Thus it appears, that the hypothesis tallies precisely with the induction of magnetism. We do not call this an explanation of the phenomenon; for the fact is, that it is the hypothesis that is explained by the phenomenon: That is, if any person be told that induced magnetism is produced by the action of a fluid, in consequence of its situation being changed, he will find, that in order to agree with the attraction of dissimilar, and the repulsion of similar poles, he must accommodate the fluid to the phenomena, by giving it the properties assigned to it by Æpinus.

76 Conformity of the hypothesis with a vast variety of phenomena.

But the agreement with this simplest possible case of the most simple example of induced magnetism, is not enough to make us adopt the hypothesis as adequate to the explanation of all the magnetic phenomena. We must confront the hypothesis with a variety of observations, to see whether the coincidence will be without exception.

When the key CB, in fig. 8. is brought below the constipated north pole N of the magnet SAN, its own moveable fluid is propelled *from* C towards B, and is disposed in CB nearly after the same manner as in SAN. Therefore the redundant fluid in the lower end of the key repels the moveable fluid in the wire BD more than the redundant matter in the upper end C attracts it; and thus the fluid is rarefied in the upper end of the wire BD, and condensed in its lower end D. CB and BD therefore are two temporary magnets, having their dissimilar poles in contact, or nearest to each other. This is all that is required for their attraction. This effect is promoted by the action of N on the wire BD, also propelling the fluid toward D; and thus increasing the mutual attraction of CB and BD. In like manner, when the key CB is held above the magnet, the moveable fluid in it is more attracted by the redundant matter in SA than it is repelled by the more remote redundant fluid in AN. The same thing happens to the fluid in the wire BD. Therefore CB and BD must attract each other; and the key will carry the wire, although the magnet is below it, and also attracts it. This singularity proceeds from the almost perfect mobility of the fluid in the two pieces of common iron, which renders their poles extremely constipated; whereas the hardness required for the fixed magnetism of the magnet prevents this complete constipation and rarefaction. This can be strictly demonstrated in the case of slender rods of iron; but we can shew, and experience confirms it, that in other cases, depending on the shape and the temper of the pieces, the wire will not adhere to the key, but to the magnet.

In the various situations and position of the key and wire represented in fig. 7. the actions of some of the poles on the moveable fluid in the iron are oblique in regard to the length of the pieces; but, since the moveable matter is supposed to be a fluid, it will still be propelled along the pieces, notwithstanding their obliquity, in the same manner as gravity makes water occupy the lower end of a pipe lying obliquely. If indeed the magnetic fluid could escape from the iron without any obstruction by the propulsion of the magnet, it could produce no attraction, or sensible motion, any more than light does in a transparent body. What is demonstrated of the electric fluid in the Supplemental article ELECTRICITY, n° 133. is equally true here. Why the fluid does not escape when it is so perfectly moveable, is a question of another kind, and will be considered afterwards; at present, the *hypothesis* is, that it does not escape.

If the key and wire have the position fig. 10 n° 1. the fluid is expelled from the parts in contact, and is condensed in the remote ends. So far from attracting each other, the key and wire must repel. They are temporary magnets, having their similar poles fronting each other. They must repel each other, if presented in a similar manner to the south pole of the magnet.

If they be presented as in n° 2. fig. 10. where the actions of both poles of the magnet are equal, the state of the fluid in them will not be affected. The redundant pole of the magnet repels the moveable fluid in both the key and the wire toward the upper ends; but the deficient pole acts equally on it in the opposite direction. It therefore remains uniformly distributed through their substance; and therefore they can exhibit no appearance of magnetism.

But if the key and wire be presented to the *same* part of the magnet, but in another position, as shewn in fig. 8. n° 3. the fluid of the key will be abstracted from C, and condensed in B, by the joint action of both poles of the magnet. The same thing will happen in the wire BD. Here, therefore, we have two magnets with their dissimilar poles touching. They will attract each other strongly; and if carried gradually toward the upper or lower end of the magnet, they will separate before the point B arrives abreast of N or S. For similar reasons, the pieces of iron presented to the middle of the magnet, as in fig. 10. will have one side a weak north pole, and the other side a weak south pole; but this will not be conspicuous, unless the pieces be broad.

This experiment shews, in a very perspicuous manner, the competency of the hypothesis to the explanation of the phenomena. When the fluid is not moved, magnetism is not induced, even on the most susceptible substance.

When a piece of iron A (fig. 10.), nearly as large as the magnet can carry, hangs at either pole, a large piece of iron B, brought near to the pole on the other side, should cause it immediately to fall. If S be the deficient pole, it causes the fluid in A to ascend to the top, and A is attracted: but, for the same reason, it causes the fluid in B to accumulate in its lower end. This redundant fluid must evidently counteract the redundant matter in S, in the induction of the magnetic state on A. Being more remote from A than S is, it cannot wholly prevent the accumulation in the upper end of A; but it renders it so trifling, that the remaining

attraction thence arising cannot support the weight of A. This is a very instructive experiment.

But if, on the contrary, we bring a large piece of iron C below the heavy key A, this piece C will have its fluid accumulated in its upper end, both by the action of A on it, and by the action of the magnet. The attraction of the magnet for A should therefore be augmented; and a magnet should carry a heavier lump of iron when a great lump is beyond it. And it is clear (we think), for similar reasons, that the magnetism of the magnet itself in fig. 11. should be increased by bringing a great lump of iron near its opposite pole: for the magnet differs from common iron only in the *degree* of the mobility of its fluid.

When a compass needle is placed opposite to the redundant pole N of a magnet AN (fig. 28.), it arranges itself magnetically. If a piece of common iron be now presented laterally to the near point of the needle, the redundant matter in the adjoining parts of the needle and the iron should make them repel; but if presented to the remote end, the redundant matter in the iron should attract the redundant fluid in that end of the needle, and that end should turn toward the iron.

A parcel of slender iron wires, carried by the pole of a magnet, as in fig. 29 should avoid each other. If N be the redundant pole, the fluid in each wire will be driven to the remote end, where it must repel the similarly situated fluid of its neighbour. The same external appearance must be exhibited by pieces of wire hanging at the deficient pole of the magnet.

The redundant pole of a magnet A (fig. 30.) being held vertically above the centre of two pieces of common iron, moveable round a slender pin, renders the middle of each deficient, and their extremities redundant; therefore they should repel each other, and spread out. The same effect should be produced by the under charged pole of A.

The redundant pole of a magnet A being applied to one branch of the piece of forked iron NCS (fig. 31.), should drive the fluid into its remote parts C, and then the branch NC should be able to induce the magnetic state on a bit of iron D. But if the deficient pole S of another magnet B be applied to the other branch, these two actions should counteract each other at C; and the iron should remain indifferent, and fall.—Yet the magnet B alone would equally cause C to carry the piece of iron.

It is surely unnecessary to demonstrate, that the consequence of this hypothesis must be, that when a magnet puts any piece of iron into the magnetic state, its own magnetism is improved. For the induced magnetism of the iron is always so disposed as to give the fluid in the magnet a greater constipation where already condensed, and to abstract more fluid from the parts already deficient. If magnetism be produced by such a fluid, a magnet must always improve by lying any how among pieces of iron.

But the case may be very different when magnets are kept in each others neighbourhood. When the overcharged poles of two magnets are placed fronting each other, the redundant fluid in each repels that in the other more than it attracts the remoter redundant iron. The magnets must therefore repel each other. Moreover, in rendering them magnetical, the repulsion of redundant fluid, or the attraction of redundant matter of some other magnet, had been employed; and when the magnet was removed, some of the constipated fluid overcame the obstruction to its uniform diffusion, and escaped into the deficient pole; what remains is withheld by the obstruction, and the restoring forces are just in equilibrio with this obstruction. If we now add to them the repulsion of redundant fluid, directed toward the deficient pole, some more of the constipated fluid must be driven that way, and the magnet must be weakened. Nay, it may be destroyed, and even reversed, if one of the magnets be very powerful, and have its own magnetism very fixed; that is, if its fluid be very redundant, and meet with very great obstruction to its motion. Hence it also should follow, that the repulsion observed between two magnets should be weaker at the same distance than their attraction, and should follow a different law. For, in the course of the experiments, the situation of the fluid in the magnets is continually changing, and approaching to a state of uniform diffusion.

Let us now examine into the sensible effect of this fluid on a magnet which cannot move from its place, but can turn on its centre like a compass needle. This scarcely requires any discussion. We should only be repeating, with regard to the redundant fluid and redundant matter, what we formerly said in regard of north pole and south pole; the little magnet must arrange itself nearly in the tangent of a magnetic curve. But it requires a more minute investigation to determine what the sensible phenomenon should be when the fluid of the little magnet is perfectly moveable. 77 Explanation of the directive power, and of polarity.

Suppose therefore a particle C (fig. 32.) of magnetic fluid, at perfect liberty to move in every direction, and acted on by the redundant and deficient poles of a magnet NAS. The redundant iron in S attracts C in the direction and with the force CF, while the redundant fluid in N repels it in the direction and with the force CD. By their joint action it must be urged in the direction and with the force CE, the diagonal of the parallelogram CDEF, which must be accurately a tangent to a magnetic curve. If this particle of fluid belong to the piece of iron nCs, which lies in that very direction, it will unquestionably be pushed towards the extremity n. The same must happen to other particles. Hence it appears that a piece of common iron in this situation and position must become a magnet, and must retain this position; only the mechanical energy of the lever may change the equilibrium of the magnetic forces a little; because when the piece of iron nCs has any sensible magnitude, the action on its different points will be a little unequal, and may compose diagonals which divide a little from the tangent.

Should the iron needle chance not to have the exact position, but not deviate very far from it, it is also clear that the fluid, not being able to escape, will press on the side toward which it is impelled; and thus will cause the needle to turn on its pivot, and finally arrange itself in magnetical and mechanical equilibrium, deviating so much the less from a tangent to a magnetic curve as the piece of iron is smaller. Any piece of common iron, held in the neighbourhood of a magnet, will become more overcharged at one end and undercharged at the other, in proportion as the position of its length comes nearer to the tangent of a magnetic curve. A slender wire held perpendicular to this position, that

is, perpendicular to the curve, ſhould not acquire any ſenſible magnetiſm, either attractive or directive.

78 Explanation of the curves formed by iron filings

We ſurely need not now employ many words to ſhew that a parcel of iron filings, ſtrewed round a magnet, ſhould arrange themſelves in the primary magnetic curves, or that when ſtrewed round two magnets they ſhould form the ſecondary or compoſite curves.

79 Explanation of tranſitory and of permanent magnetiſm, and of indifferent and determinate magnetiſm.

Let us now enquire more particularly into the modifications of this accumulation of magnetic fluid which may reſult from the nature of the piece of iron, as it is put into the magnetic ſtate. The propelling force of A acts againſt the mutual repulſion of the particles of fluid in B, and alſo againſt the obſtruction to its motion through the pores of B. The greater this obſtruction, the ſmaller will be the accumulation which ſuffices, in conjunction with the obſtruction and the attraction of the deſerted iron, to balance the propulſive force of the redundant fluid in the overcharged pole of A. This circumſtance therefore muſt limit the accumulation that can be produced in a given time. Therefore the magnetiſm produced on ſoft ſteel or iron ſhould be greater than that produced in hard ſteel at the ſame diſtance. Hence the great advantage of ſoft poles, or of armour, or of capping, to a loadſtone, or to a bundle of hard bars. The beſt form and dimenſions of this armour is certainly determinable by mathematical principles, if we knew the law of magnetical action, and the diſpoſition of the magnetiſm in our loadſtone; but theſe are too imperfectly known in all caſes for us to pretend to give any exact rules. We muſt decide experimentally by making the caps large at firſt, and reducing them till we find the loadſtone carry leſs; then make them a ſmall matter larger. The chief things to be minded are the purity, the uniformity, and the ſoftneſs of the iron, and the cloſeſt poſſible contact.

If the obſtruction reſemble that to motion through a clammy fluid, the final accumulation in hard ſteel may be nearly equal to that in iron, but will require much longer time. Alſo, becauſe ſuch obſtruction to the motion of the fluid will nearly balance the propelling force in parts that are far removed from the magnet, the accumulation will begin thereabouts, while the bar beyond is not yet affected. A redundant pole will be formed in that place. This will operate on what is *immediately* beyond it, driving the fluid farther on, and occaſioning another accumulation at a ſmall diſtance. This may produce a ſimilar effect in a ſtill ſmaller degree farther on. Thus the ſteel bar will have the fluid alternately condenſed and rarefied, and contain alternate north and ſouth poles. This ſtate of diſtribution will not be permanent; fluid will be gradually changing its place; theſe poles will gradually advance along the bar, the remoter poles becoming gradually more diffuſe and faint; and it will not be till after a very long time that a regular magnetiſm with two poles will be produced. To ſtate mathematically the procedure of this mechaniſm would require many pages. Yet it may be done in ſome ſimple caſes, as Newton has ſtated the proceſs of aerial undulation. But we cannot enter upon the taſk in this limited diſſertation. What is ſaid in the Supplementary article ELECTRICITY (n° 217, 218.) on the diſtribution of the electric fluid in an imperfect inſulator, will aſſiſt the reader to form a notion of the ſtate of magnetiſm during its induction. That ſuch alternations proceed from ſuch mechaniſm, we have ſufficient proof in the inſtances mentioned in the former part of this article. The wave, or curl, produced on the ſurface of a clammy fluid, is a phenomenon of the ſame kind, and owing to ſimilar cauſes.

When the magnet which has produced all theſe changes is removed, it is evident that a part of this accumulation will be undone again. The repulſion of the condenſed fluid, and the attraction of the deſerted iron, will bring back ſome of the fluid. But it is very evident, that a part of the accumulation will remain, by reaſon of the obſtruction to its motion in returning; and this remainder muſt be ſo much the greater as the obſtruction to the change of ſituation is greater. In ſhort, we cannot doubt but that the magnetiſm which remains will be greater in hard than in ſpring tempered ſteel.

80 Rationale of the rules for making magnets.

Thus have we traced the hypotheſis in a great variety of circumſtances and ſituations, and pointed out what ſhould be the external appearance in each. We did not, in each inſtance, mention the perfect coincidence of theſe conſequences with what is really obſerved, but left it to the recollection of the reader. The coincidence is indeed ſo complete, that it ſeems hardly poſſible to refuſe granting that nature operates in this or ſome very ſimilar manner. We get ſome confidence in the conjecture, and may even proceed to explain complicated phenomena by this hypothetical theory. We might proceed to ſhew, that the effects of all the methods practiſed by the artiſts in making artificial magnets are eaſy conſequences of the hypotheſis: but this is hardly neceſſary. We ſhall juſt mention ſome facts in thoſe proceſſes which have puzzled the naturaliſts.

1. A ſtrong magnet is known to communicate the greateſt magnetiſm to a bar of hard ſteel; but Muſchenbroek frequently found, that a weak magnet would communicate more to a ſoft than to a hard bar.

Explanation. When the magnet is ſtrong enough to impregnate both as highly as they are capable of, the hard bar muſt be the ſtrongeſt; but if it can ſaturate neither, the ſpring-tempered bar muſt be left the moſt magnetical.

2. A ſtrong magnet has ſometimes communicated no higher magnetiſm than a weaker one; both have been able to ſaturate the bar.

3. A weak magnet has often impaired a ſtrong one by ſimply paſſing along it two or three times; but a piece of iron always improves a magnet by the ſame treatment.

Explanation. When the north pole of a weak but hard magnet is ſet on the north pole of a ſtrong one, it muſt certainly repel part of the fluid towards the other end, and thus it muſt weaken the magnet. When it is carried forward, it cannot repel this back again, becauſe it is not of itſelf ſuppoſed capable of making the magnet ſo ſtrong. But the end of a piece of iron, always acquiring a magnetiſm oppoſite to that of the part which it touches, muſt increaſe the accumulation of fluid where it is already condenſed, and muſt expel more from thoſe parts which are already deficient.

4. All the parts of the proceſs of the double touch, as practiſed by Meſſrs Mitchell and Canton, are eaſily explained by this hypotheſis. A particle of fluid p (fig. 33.), ſituated in the middle between the two magnets, is repelled in the direction $p\,e$ by the redundant pole of the magnet AN, whoſe centre of effort is ſuppoſed to be

ing at A. It is attracted with an equal force in the direction *p d* toward the centre of effort of the deficient pole of *N S*. By these combined actions it is impelled in the direction *p f*. Now it is plain that, although by increasing the distance between *N* and S, the forces with which these poles act on *p* are diminished, yet the compound force *p f* may increase by the diminution of the angle *d p e*. If the action is as $\frac{1}{x^2}$, *p f* will be greatest when $\frac{\text{Cof. } d p f}{d p^2}$ is a maximum, or (nearly) when Sin.^{2} $d p f \times$ Cof. $d p f$ is a maximum: but this depends on the place of the centre of effort. We can, however, gather from this observation, that the nearer we suppose the centres of effort of the poles N and S to the extremities of the magnets, the nearer must they be placed to each other. But we must also attend to another circumstance; that by bringing the poles nearer together, although we produce a greater action on the intervening fluid, this action is exerted on a smaller quantity of it, and therefore a less effect may be produced. This makes a wider position preferable; but we have too imperfect a knowledge of the circumstances to be able to determine this with accuracy. The unfavourable action on the fluid beyond the magnets must also be considered. Yet all this may be ascertained with precision in some very simple instances, and the determination might be of service, if we had not a better method, independent of all hypotheses or theory; namely, to place the magnets at the distance where they are *observed* to lift the heaviest bar of iron; then we are certain that their action is most favourable, all circumstances being combined.

We also see a sufficient reason for preferring the position of the magnets employed by Mr Antheaume (and before him by Mr Servington Savery), in his process for making artificial magnets. The form of the parallelogram *d p e f* is then much more favourable, the diagonal *p f* being much longer.

We also see, in general, that, by the method of double touch, a much greater accumulation of fluid may be produced than by any other known process.

And, lastly, since no appearances indicate any difference between natural and artificial magnetism, this hypothesis is equally applicable to the explanation of the phenomena of natural magnetism; such as the position of the horizontal, and of the dipping needle, and the impregnation of natural loadstones.

Having such a body of evidence for the aptitude of this hypothesis for the explanation of phenomena, it will surely be agreeable to meet with any circumstances which render the hypothesis itself more probable. These are not wanting: although it must be acknowledged that nothing has yet appeared, besides the phenomena of magnetism, to give us any indication of the existence of such a fluid; but there are many particulars in their appearance which greatly resemble the mechanical properties of a fluid.

81
Probability of the existence of magnetical fluid.

Heating a rod of iron, and allowing it to cool in a position perpendicular to the magnetic direction, destroys its magnetism. Iron is expanded by heat. If the particles of the magnetic fluid are retained between those of the iron, notwithstanding the forces which tend to diffuse them uniformly, they may thus escape from between the ferruginous particles which withheld them. For similar reasons, magnetism should be acquired by heating a bar and letting it cool in the magnetic direction. But, besides this evident mechanical *momentum* of motion, the union of fire (or whatever name the theologists may choose to give to the cause of expansion and of heat) with the particles of iron may totally change the action of those particles on the particles of fluid in immediate contact with them; nay, it may even change the sensible law of action between magnet and magnet. Of this no one can doubt who understands the application of mathematical science to corpuscular attraction (See Boscovich, *Suppl.*) A change may be produced in the action between magnets without any remarkable change happening in the actions within the magnet, and it may be just the reverse. The union of fire with the magnetic fluid may increase the mutual repulsion of its parts, as it does in all aerial fluids or gases. This alone would produce a dissipation of some magnetism. It may increase the attraction (at insensible distances) between the fluid and the iron, as it does in numberless cases in chemistry.

82
Farther grounds of belief.

It is well known that violently knocking or hammering a magnet weakens its force, and that hammering a piece of iron in the magnetic direction will give it some magnetism. By this treatment the parts of the iron are put into a tremulous motion, alternately approaching and receding from each other. In the instants of their recess, the pent-up particles of the fluid may make their escape. A quantity of small shot may be uniformly mixed with a quantity of wheat, and will remain so for ever, if nothing disturb the vessel; but continue to tap it smartly with a stick for a long time, and the grains of small shot will escape from their confinements, and will all go to the bottom. We may conceive the particles of magnetic fluid to be affected in the same way. The same effect is produced by grinding or filing magnets and loadstones. The latter are frequently made worthless by grinding them into the proper shape. This should be avoided as much as possible, and it should always be done in moulds made of soft iron and very massive; but this will not always prevent the dissipation of *strong* magnetism. As a farther reason for assigning this cause for the dissipation in such cases, it must be observed (Muschenbroek takes notice of it), that a magnet or loadstone may be ground at its neutral point without much damage. But we had the following most distinct example of the process. A very fine artificial magnet was suspended by a thread, with its south pole down. A person was employed to knock it incessantly with a piece of pebble, in such a manner as to make it ring very clearly, being extremely hard and elastic. Its magnetism was examined from time to time with a very small compass needle. In three quarters of an hour, its magnetism was not only destroyed, but the lower end shewed signs of a north pole. The same magnet was again touched, and made as strong as before, and was then wound about very tight with wetted whipcord, leaving a small part bare in the middle. It was again knocked with the pebble, but could no longer ring. At the end of three quarters of an hour its magnetism was still vigorous, and was not near gone after two hours and a quarter. We discharged a Leyden jar (coated with gold leaf) in the same way. It stood on the top of an axis; and while this was turned round, the edge was rubbed with a very dry cork filled with

with rosin, and soldered to the end of a glass rod. This made the piece sound like the glass of a harmonica. One of them was split in this operation.

A small bar of steel was heated red hot and tempered between two strong magnets lying in the low box filled with water, and was more strongly impregnated in this way than in any other that we could think of for a bar of that shape. It has not yet been ascertained in what temperature it is most susceptible of magnetism, but it was considerably hotter than to be just visible in a dark place. It is no objection to our way of conceiving magnetism, that the fluid is immoveable or inactive when the iron is red hot. Either of these, or both of them, may result from the union with the cause of heat. Even a particular degree of expansion may so change the law of action as to make it *immoveable*; or the union with caloric may render it *inactive* at all sensible distances. We cannot but think, that some very instructive facts might be obtained by experiments made on iron in the moment of its production, and changes in various chemical processes. All magnetism is gone when it is united with sulphur and arsenic in the greatest number of ores; and when it is in the state of an ochre, rust, æthiops, or solution in acids; and when united with astringent substances, such as galls. When, and in what state, does it become magnetic? And whence comes the fluid of Æpinus? It were worth while to try, whether magnets have any influence in the formation or crystallization of the martial salts; and what will be their effect on iron when precipitated from its solutions by another metal, &c. &c.

83 Why magnets have always more than one pole.

There remains one remarkable fact to be taken notice of, which, in one point of view, is a confirmation of the hypothesis, but in another presents considerable difficulties. It is well known, that no magnet has ever been seen which has but one pole; that is, on the hypothesis of Æpinus, which is wholly redundant, or wholly deficient. If all magnetism be either the immediate or the remote effect of the great magnet contained in the earth, and if it be produced by induction, without any communication of substance, but only by changing the disposition of the fluid already in the iron, we never should see a magnet with only one pole. It must be owned, that we never can make such a magnet by any of the processes hitherto described; but the existence of such does not seem impossible. Supposing a magnet, of the most regular magnetism, having only two poles; and that we cut it through at the neutral point, or that we cut or break off any part of it—the fact is, (for the experiment has been tried ever since men began to speculate about magnetism), that each part becomes an ordinary magnet, with two poles, one of which is of the same kind as before the separation. The question now is, What should happen according to the theory maintained by Æpinus?—*Tentam. Theor. Electr. et Magnetismi*, p. 104, &c.

Let NAS (fig. 24.) be a magnet, of which N is the overcharged pole. Let the ordinates of the curve DAE express the difference between the natural density of the fluid, in a state of uniform diffusion, and its density as it is really disposed in the magnet. The area pn ND will there express the quantity of redundant fluid in the part nN, and the area qESm express the fluid wanting in the part Sm. The intersection A marks that part of the magnet where the fluid is of its natural density. Suppose the part Nn to be separated from the rest, containing the redundant fluid NDpn. The tendency of this fluid to escape from the iron with which it is connected will be greater (Mr Æpinus thinks) than before, because its tendency to quit the magnet formerly was opposed by the attractions of the redundant matter contained in AS. This is certainly true of the extremity N; and, perhaps of all the old external surface. Fluid will therefore escape. Suppose that so much has quitted the iron that the point n has the fluid of its natural density, as is represented in n° 3. there is still a force operating at n, tending to escape, arising from the repulsion of all the redundant fluid nDN. If this be sufficient for overcoming the obstruction, it will really escape, and the iron will be left in the state represented by n° 4. with an overcharged part fN, and an undercharged part fn.

In like manner, the tendency of the magnetic fluid surrounding the magnet to enter into its deficient pole, will be greater when it is separated from the other, not being checked by the repulsion of the redundant fluid in that other

Mr Æpinus relates some experiments which he made on this subject. The general result of them was, that the moment the parts were separated, each had two poles, and that the neutral point of each fragment was much nearer to the place of their former union than to their other ends. In a quarter of an hour afterward, the neutral points had advanced nearer to their middles, and continued to do so, by very small steps, for some hours, and sometimes days, and finally were stationary in their middles.

We acknowledge, that this reasoning does not altogether satisfy us, and that the gradual progress of the neutral point toward the middle of each piece, although agreeable to what should result from an escape of fluid, is not a proof of it. We knew already, that the production of magnetism is a progressive thing; and we should have expected this change of the situation of the neutral point, whatever be the nature of magnetism. There is something similar to this, and perhaps equally puzzling, in the immediate recovery of magnetism which has been weakened by heat, it is partly recovered on cooling.

But our chief difficulty is this: At the point A (fig. 34.) every thing is in equilibrium before the fracture. The particle A is repelled by the redundant fluid in AN, and attracted by the redundant matter in AS; yet it does not move, for the magnetism is supposed to have permanency. Therefore the obstruction at A cannot be overcome by the united repulsion of AN and attraction of AS. Nor can the obstruction at N be overcome by the difference of these two forces. Now suppose AS annihilated. The change made on the state of things at A is surely greater than that at N, because the force abstracted is greater, the distance being less. It does not clearly appear, therefore, that the removal of AS should occasion an efflux at N. This, however, is not impossible; because the fluid may be so disposed, by great constipation near N, and no great excess of density near A, that a smaller change at N may produce an efflux there. But surely the tendency to escape at A must now be diminished, instead of being greater after the fracture. And if any escape from N, this will still more diminish that tendency to escape

from

from A. It does not therefore appear a clear consequence of the general theory, that the constipated fluid should escape; and more particularly, that A should become deficient. And with respect to the entry of fluid into the other fragment, and its becoming overcharged at *m*, the reasoning seems still less convincing. The steps of the physical process in the two parts of the original magnet are by no means convertible or counterparts of each other. There is nothing in the part AS to resemble the force of repulsion really exerting itself in the corresponding point of AN. There would be, if there were a particle of fluid in that place; but there is not. The tendency therefore of external fluid to enter there, does not resemble the tendency of the internal fluid to expand and dissipate. It is true, indeed, the discourse should be confined to points of the surface. But the internal motion must also be considered; and the great objection always remains, namely, that the obstruction at A (n° 1.) or at *n* (n° 3.) is sufficient to prevent the passage of a particle of fluid from the pole AN into the pole AS, when urged by the repulsion of the fluid in the one and the attraction of the iron in the other; and yet will not prevent the escape of a particle when one of those causes of motion is removed. Add to this, that the whole hypothesis assumes as a principle, that the resistance to escape from any point is greater than the obstruction to motion through the pores. This is readily granted; for however great we suppose the attraction, in the limits of physical contact, it will be no obstruction to motion through the pores, because the particle is equally affected by the opposite sides of the pores; whereas, in quitting the body altogether, there is nothing beyond the body to counteract the attraction by which it is retained.

There seems something wanting to accommodate this beautiful hypothesis of Mr Æpinus to this remarkable phenomenon; and the coincidence is otherwise so complete, that we are almost obliged to conclude that it is merely a deficiency, arising from our not having a sufficient knowledge of the law of magnetic action. This is quite sufficient: For it may be strictly demonstrated, that if the magnetic action decreases in higher ratio than that of the squares of the distances, the permanency of the fluid in any particular disposition has scarcely any dependence on the particles at any sensible distance, and is affected only by the *variations* of its density (See Electricity, *Suppl.* n° 217. for a case somewhat similar). Therefore, if the fluid be so disposed, that its density may be represented by the ordinates of such a curve as is drawn in fig. 34. having its two extremities concave toward the axis, and a point of contrary flexure at A, the tendency to escape at A will be the greatest possible; and when the magnet is broken at A (n° 1.), or when the fluid has taken the arrangement represented by n° 3. it *cannot* stop there, and *must* become deficient in that part. Now, it must be acknowledged, that we are not absolutely certain that the magnetic action is in the precise inverse duplicate ratio of the distance. All that we are certain of is, that it is much nearer to it than to either the inverse simple or inverse triplicate ratio. We own ourselves rather disposed to ascribe the present difficulty to our ignorance of some circumstance, purely mathematical, overlooked, or mistaken, than to think a conjecture unfounded, which tallies so accurately with such a variety of phenomena.

We may here observe, that we are not altogether satisfied with Æpinus's form of the experiment. He did not break a magnet; he set two steel bars end to end, and touched them as one bar, making the magnetism perfectly regular; he then separated them, and found that each had two poles. But was he certain that, when joined, they made but one magnet? We have sometimes succeeded in doing this, as we thought, by the curves of iron filings; but on putting the needle with which we were examining their polarity into proper situations, we sometimes found it in the second intersection of the secondary curves, shewing that the bars were really two magnets, and not one.

On the other hand, when a piece is broken off from a magnet, the succussion and elastic tremor into which the parts are thrown, and even the bending previous to the fracture, may give opportunity to a dissipation, which could not otherwise happen. The parts should be separated by corrosion in an acid, and the gradual change of magnetism should be carefully noted. The writer of this article has made some experiments of this nature, the results of which present some curious observations; but they are not yet brought to a conclusion that is fit to be laid before the public.

85 Hypothesis of Prevôt.

Mr Prevôt of Geneva, in a dissertation on the origin of magnetic forces, endeavours to give a theory which obviates the only difficulty in that of Æpinus; but it is incomparably more complex, employing two fluids, which by their union compose a third, which he calls combined fluid. There is much ingenuity, and even mathematical address, in adjusting the relative properties of those fluids. But some of them are palpably incompatible; *ex. gr.* the particles of each attract each other, but those of the other kind most strongly; yet they are both elastic like air. This is surely inconceivable.—Granting this, however, he suits his different attractions, so that a strong elective attraction of the combined fluid for iron decomposes part of the fluid in the iron, and each of its ingredients occupies opposite ends of the bar: then will the bars approach or recede, according as the near ends contain a different or the same ingredient. All this is operated without repulsion.

But the whole of this is mere accommodation, like Æpinus's, but so much more complex, that it requires very intense contemplation to follow the author through the consequences. Add to this, that his attractions are operated by another fluid, infinitely more subtle than either of those already mentioned, every particle of these being, as it were, a world in comparison of those of the other. In short, he adopts all the extravagant suppositions of Le Sage of Geneva, and every thing is ultimately impulsion. Nor is the contrivance for obviating the difficulty (so often mentioned) at all clear and convincing; and it is equally gratuitous with the rest. We cannot think this hypothesis at all intitled to the name of *explanation*.

86 Remarks on hypotheses.

This must serve for an account of the hypothesis of Æpinus. The philosophical reader will see, that however exactly it may tally with every phenomenon, it cannot be called an explanation of the phenomena; because it is the phenomena which explain the hypothesis, or give us the characters of the magnetic fluid, if such

such fluid exists But we are not obliged to admit this existence, as we admit that to be the true decyphering of a letter which makes sense of it. In that case we know both parts of the subject—the characters and the sounds; but are ignorant which corresponds to which. Did we see a fluid abstracted from one part of a bar and constipated in another, and perceive the abstraction and constipation always accompanied by the observed attractions and repulsions, the rules of philosophical discussion, nay, the constitution of our own mind, would oblige us to assign the one as the cause or occasion of the other. But this important circumstance is wanting in the present case. We think, however, that it merits a close attention; and we entertain great hopes of its being one day completed, by including this single exception.

At the same time, it must be owned, that it gives no extension of knowledge; for it can have no greater extension than the phenomena on which it is founded, and cannot, without risk of error, be applied to an untried case, of a kind dissimilar in its nature to the phenomena on which it is founded. We doubt not but that its ingenious author would have said, that a bit broken off from the north pole of a magnet would be wholly a north pole, if he had not known that the fact was otherwise.

But this hypothesis greatly aids the imagination in conceiving the process of the magnetical phenomena. The more we study them, the more do they appear to resemble the protrusion of a fluid through the parts of an obstructing body. It proceeds gradually. It may be, as it were, overdone, and regorges when the propelling cause is removed. The motion is aided by what we know to aid other obstructed motions. As a fluid would be constipated in all protuberances, so the faculty of producing the phenomena is greater in all such situations, &c. &c. This, joined to the impossibility of speaking, with clearness of conception, of the propagation of powers without the protrusion of something in which they inhere, gives it a hold of the imagination which is not easily shaken off.

To say that nothing is explained when the attraction of the fluid is not explained, and that this is the main question, gives us little concern. We offer no explanation of this attraction, more than of the attraction of gravity. There is nothing contrary to the laws of human intellect, nothing inconsistent with the rules of reasoning, in saying, that things are so constituted, that when two particles are together, they separate, although we are ignorant of the immediate cause of their separation. Those who think that all motion is performed by impulsion, and who explain magnetism by a stream of fluid circulating round the magnet, must have another fluid to impel this fluid into its curvilineal path; for they insist, that the planets are so impelled. Then they must have a third fluid to deflect the vertical motions of the second, and so on without end. This is evident, and it is absurd. But we have said enough in the article IMPULSION, *Suppl.* to shew that all *hypotheses* framed on purpose to explain action *e distanti* by impulsion are illogical; because impulsion requires explanation as much as the other, and neither the one nor the other will ever be resolved into any thing but the FIAT of the Allwise Author of the universe.

We conclude with desiring the reader to remark, that the explanation which we have given of the magnetical phenomena is independent of the hypothesis of Æpinus, or any hypothesis whatever. We have narrated a variety of very distinguishable facts, and have marked their distinctions. We have been able to reduce them to general classes; and even to groupe those classes into others still more general; and at last, to point out one which is discoverable in them all. This is giving a philosophical theory, in the strictest sense of the word; because we shew, in every case, the modification of the general fact which allots it this or that particular place in the classification. Thus we have shewn that the polarity or directive power of magnets is only a modification of the general fact of attraction and repulsion. Dr Gilbert's theory of *terrestrial* magnetism is indeed a hypothesis, and we enounced it as such. It only claims probability, and we apprehend that a very high degree of credit will be given to it. 87 The preceding theory is not a hypothesis.

We hope that many of our readers will have their curiosity excited by the account we have given of Æpinus's theory. To such we earnestly recommend the serious perusal of his book *Tentamen Theoriæ Electricitatis et Magnetismi, Auct. F. Æpino, Petropoli*, 1759 Van Swinden has included a very good abstract of it in his 2d volume *Sur l'Electricité*, written by Professor Steiglehner of Ratisbon or Ingolstadt. The mathematical part is greatly simplified, and the whole is presented in a very clear and accurate manner. Mr Van Swinden is a professed foe to all hypotheses; but he is not moderate, and we wish that we could say that he is candid. He attacks every thing; and takes the opportunity of every analogy pointed out by Æpinus between magnetism and electricity to repeat the first sentence of his dissertation, namely, that magnetism and electricity are not the same; a thing that Æpinus also maintains. But he even charges Æpinus with a mistake in his fundamental equations, which invalidates his whole theory. He says that Æpinus has omitted one of the acting forces assumed in his hypothesis. This is a most groundless charge; and we own that we cannot conceive how Van Swinden could fall into such a mistake. We are unwilling to call it intentional, for the mere purpose of raising a man of straw to knock him down again. Abbé Haüy of the French Academy has also published an abridgment of Æpinus's theory, with many excellent remarks, tending to clear the theory of the only defect that has been found in it. This work was much approved of, and recommended by the Academy. We have not had the good fortune to see a copy of it.

88 Analogy of magnetism to electricity.

The reader cannot but have remarked the close analogy between the magnetical phenomena and those of induced electricity; indeed, all the phenomena of attraction and repulsion are the same in both. The mechanical composition of those actions produces a directive power and a polarity, in electrical as well as in magnetical bodies. We can make an electrical needle which will arrange itself, with respect to the overcharged and undercharged ends of a body electrified by mere position, just as a compass needle is arranged by a magnet. We can touch a stick of sealing wax in the manner of the double touch, so as to give it poles of considerable force and durability. As a red hot steel bar acquires permanent poles by quenching it near a magnet, so melted wax acquires them by freezing in the neighbourhood of a positive

poſitive and negative electric. Some have inferred a ſameneſs of origin of theſe two ſpecies of powers from theſe various circumſtances of reſemblance: but the original cauſes ſeem to be diſtinct on many accounts. Electricity is common to all bodies. The cauſe of magnetiſm can operate only on iron. Although lightning or an electrical ſhock gives polarity to a needle, we need not infer the identity of the cauſe becauſe the polarity which it gives is always the ſame with that given by great heat; and there is always intenſe heat in this operation. The phenomenon which looks the moſt like an indication of identity of the origin of electricity and magnetiſm is the direction of the rays of the aurora borealis—they converge to the ſame point of the heavens to which the elevated pole of the dipping needle directs itſelf. But this is by no means a ſufficient foundation for eſtabliſhing a ſameneſs. Electricity and magnetiſm may, however, be related by means of ſome powers hitherto unknown. But we are decidedly of opinion, that the electric and magnetic fluids are totally different, although their mechanical actions are ſo like that there is hardly a phenomenon in the one which has not an exact counterpart in the other. But we ſee them both operating, with all their marks of diſtinction, in the ſame body; for iron and loadſtones may be electrified, like any other body, and their magnetiſm ſuffers no change or modification. We can ſet theſe two forces in oppoſition or compoſition, juſt as we can oppoſe or compound gravity with either. While the iron filings are arranging themſelves round a magnet, the mechanical action of electricity may be employed either to promote or hinder the arrangement. They are therefore diſtinct powers, inherent in different ſubjects.

But there are abundance of other phenomena which ſhew this diverſity. There is nothing in magnetiſm like a body overcharged or undercharged *in toto*. There is nothing which indicates the preſence of the fluid to the other ſenſes—nothing like the ſpark, the ſnap, the viſible diſſipation; becauſe the magnetic fluid enters into no union with air, or any thing but iron. There is nothing reſembling that inconceivably rapid motion which we ſee in electricity; the quickeſt motion of magnetiſm ſeems inferior (even beyond compariſon) with the ſloweſt motion along any electric conductor. Therefore there is no poſſibility of diſcharging a magnet as we diſcharge a coated plate. Indeed, the reſemblance between a magnet and a coated plate of glaſs is exceedingly ſlight. The only reſemblance is between the magnet and an inconceivably thin ſtratum of the glaſs, which ſtratum is poſitive in one ſide and negative in the other. The only perfect reſemblance is between the induced magnetiſm of common iron, and the induced electricity of a conductor.

Beſides theſe original works, we have ſeveral diſſertations on magnetical vortices by Des Cartes, Bernoulli, Euler, Du Tour, &c. publiſhed in the collections of the works of thoſe authors, and many diſſertations in the memoirs of different academies; and there are many popular treatiſes by the traders in experimental philoſophy in London and Paris. Dr Gown Knight, the perſon in Europe who was moſt eminently ſkilled in the knowledge of the phenomena, alſo publiſhed a diſſertation intitled, *An attempt to explain the Phenomena of Nature by two principles, Attraction and Repulſion*, Lond. 1748, 4to, in which he has included a theory of magnetiſm. It is a very curious work, and ſhould be ſtudied by all thoſe who have recourſe without ſcruple to the agency of inviſible fluids, when they are tired of patient thinking. They would there ſee what thought and combination are neceſſary before an inviſible fluid can be really fitted for performing any office we chooſe to aſſign it. And they will get real inſtruction as to what ſervices we may expect of ſuch agents, and from what taſks they muſt be excluded. The Doctor's theory of magnetiſm is very unlike the reſt of the performance; for he does not avail himſelf of the vaſt apparatus of propoſitions which he had eſtabliſhed, and adopts without any nice adjuſtment the moſt common notions of an impulſive vortex. Both the production and maintenance of this vortex, and its mode of operation, are irreconcileable with the acknowledged laws of impulſion.

Si quid noviſti rectius iſtis, candidus imperti—ſi non his utere mecum.

APPENDIX.

Investigation of the magnetic curve.

We have been favoured with the following inveſtigation of the curves, to which a needle of indefinite minuteneſs will be a tangent, by Mr Playfair, Profeſſor of Mathematics in the Univerſity of Edinburgh.

Two magnetical poles being given in pofition, the force of each of which is fuppofed to be as the mth power of the diftance from it reciprocally, it is required to find a curve, in any point of which a needle (indefinitely fhort) being placed, its direction, when at reft, may be a tangent to the curve?

1. Let A and B (fig. 35.) be the poles of a magnet, C any point in the curve required; then we may fuppofe the one of thefe poles to act on the needle only by repulfion, and the other only by attraction, and the direction of the needle, when at reft, will be the diagonal of a parallelogram, the fides of which reprefent thefe forces. Therefore, having joined AC and BC, let AD be drawn parallel to BC, and make $\frac{1}{AC^m} : \frac{1}{BC^m} :: AC : AD$; join CD, then CDF will touch the curve in C.

2. Hence an expreffion for AF may be obtained. For, by the conftruction, $AD = \frac{AC^{m+1}}{BC^m}$, and fince $BC : AD :: BF : FA$, and $BC - AD : AD :: AB : AF$, we have $AF = \frac{AB \times AC^{m+1}}{BC^{m+1} - AC^{m+1}}$.

3. A fluxionary expreffion for AF may alfo be found in terms of the angles CAB, ABC. In CF take the indefinitely fmall part CH, draw AH, BH, and from C draw CL perpendicular to AH and CK to BH. Draw alfo BC and AM at right angles to FH. Let the angles $CAB = \phi$, and $CBA = \psi$; then $CAH = \dot{\phi}$, and $CBH = -\dot{\psi}$; alfo $CL = AC \times \dot{\phi}$, and $CK = -BC \times \dot{\psi}$. Now $HC : CL :: AC : AM = \frac{AC^2 \times \dot{\phi}}{HC}$; and for the fame reafon $BC = -\frac{BC^2 \times \dot{\psi}}{HC}$. Therefore fince $AF : FB :: AM : BC$, $AF : FB :: \frac{AC^2 \times \dot{\phi}}{HC} : -\frac{BC^2 \times \dot{\psi}}{HC}$, and $AF : AB :: \text{fin.}\,\psi^2\,\dot{\phi} : -\text{fin.}\,\psi^2\,\dot{\phi} - \text{fin.}\,\phi^2\,\dot{\psi}$; wherefore if $AB = a$, $AF = \frac{-a\,\dot{\phi}\,\text{fin.}\,\psi^2}{\dot{\psi}\,\text{fin.}\,\phi^2 + \dot{\phi}\,\text{fin.}\,\psi^2}$.

4. If this value of AF be put equal to that already found, a fluxionary equation will be obtained, by the integration of which the curve may be constructed. Becaufe $AF = \frac{AB \times AC^{m+1}}{BC^{m+1} - AC^{m+1}}$; and fince $AC = \frac{a\,\text{fin.}\,\psi}{\text{fin.}\,(\phi + \psi)}$, and $BC = \frac{a\,\text{fin.}\,\phi}{\text{fin.}\,(\phi + \psi)}$, we have by fubftitution $AF = \frac{a\,\text{fin.}\,\psi^{m+1}}{\text{fin.}\,\phi^{m+1} - \text{fin.}\,\psi^{m+1}} = -\frac{a\,\dot{\phi}\,\text{fin.}\,\psi^2}{\dot{\psi}\,\text{fin.}\,\phi^2 + \dot{\phi}\,\text{fin.}\,\psi^2}$. Hence, $\text{fin.}\,\phi^2 \times \dot{\psi}\,\text{fin.}\,\psi^{m+1} + \dot{\phi}\,\text{fin.}\,\psi^{m+3} = -\text{fin.}\,\psi^2 \times \dot{\phi}\,\text{fin.}\,\phi^{m+1} + \dot{\phi}\,\text{fin.}\,\psi^{m+3}$, and therefore $\dot{\psi}\,\text{fin.}\,\psi^{m-1} = -\dot{\phi}\,\text{fin.}\,\phi^{m-1}$; and alfo, $\int \dot{\psi}\,\text{fin.}\,\psi^{m-1} + \int \dot{\phi}\,\text{fin.}\,\phi^{m-1} = C$.

5. Thefe fluents are eafily found when m is any whole pofitive number.

If $m = 1$, we have $\dot{\psi} + \dot{\phi} = 0$.
$m = 2$, $\dot{\psi}\,\text{fin.}\,\psi + \dot{\phi}\,\text{fin.}\,\phi = 0$.
$m = 3$, $\dot{\psi}\,\text{fin.}\,\psi^2 + \dot{\phi}\,\text{fin.}\,\phi^2 = 0$.
$m = 4$, $\dot{\psi}\,\text{fin.}\,\psi^3 + \dot{\phi}\,\text{fin.}\,\phi^3 = 0$, &c.
Therefore, &c.
Alfo if $m = 1$, $\phi + \psi = C$.
$m = 2$, $\text{cof.}\,\phi + \text{cof.}\,\psi = C$.
$m = 3$, $-\text{fin.}\,2\phi + 2\phi - \text{fin}\,2\psi + 2\psi = C$.
$m = 4$, $\text{cof}\,3\phi - 9\,\text{cof.}\,\phi + \text{cof}\,3\psi - 9\,\text{cof.}\,\psi = C$, &c. &c.

The firft of the above equations belongs to a fegment of a circle defcribed upon AB, which therefore would be the curve required if the magnetical force were inverfely as the diftances.

If the magnetical force be inverfely as the fquare of the diftance, that is, if $m = 2$, $\text{cof.}\,\phi + \text{cof.}\,\psi$ is equal to a conftant quantity. Hence if, befide the points A and B, any other point be given in the curve, the whole may be defcribed. For inftance, let the point E (fig. 36.) be given in the curve, and in the line DE which bifects AB at right angles. Defcribe from the centre A a circle through E, viz. QER; then AD being the cofine of DAE to the radius AE, the fum of the cofines of $\phi \times \psi$ will be everywhere (to the fame radius) = 2 AD = AB. Therefore to find E, the point in which any other line AN, making a given angle with AB, meets the curve, draw from N, the point in which it meets the circumference of the circle QER, NO, perpendicular to AB, fo that AO may be the cofine of NAO, and from O toward A take OP = AB, then AP will be the cofine of the angle ABE; fo to find BE′, draw PQ perpendicular to AP, meeting the circle in Q; join AQ, and draw BE′ parallel to AQ, meeting AE′ in E′, the point E′ is in the curve. In this way the other points of the curve may be found.

The curve will pafs through B, and will cut AB at an angle of which the cofine = RB. If then E be fuch, that AE = AB, the curve will cut AB at right angles. If E″ be more remote from A, the curve will make with AB an obtufe angle toward D; in other cafes it will make with it an acute angle.

A conftruction fomewhat more expeditious may be had by defcribing the femicircle AFB, cutting AE in F, and AE′ in N, and defcribing a circle round A, with the diftance AL = 2AF, cutting AE in L. If AG be applied in the femicircle AFB = NL, AG muft cut AN in a point E of the curve, becaufe AN + BG = 2 AF, and AN and GB are cofines of the angles at A and B.

As the lines AN and BG may be applied either above or below AB, there is another fituation of their interfection E′. Thus A n being applied above, and B g below, the interfection is in e. The curve has a branch extending below A; and if D e be made = DF, and B e be drawn, it will be an affymptote to this branch. There is a fimilar branch below B. But thefe portions of the curve evidently fuppofe an oppofite direction of one of the two magnetic forces, and therefore have no connection with the pofition of the needle.

We omitted the inferting in its proper place, n° 65. Add.
a hypothefis of the celebrated aftronomer Tobias Mayer, n° 6
of Gottingen, by which the direction of the mariner's needle in all parts of the earth may be determined. He fuppofes that the earth contains a very powerful magnet of inconfiderable dimenfions, which arranges the needle according to the known laws of magnetifm. The centre of this magnet was diftant from the centre of the earth about 480 Englifh miles in 1756, and a line joining thefe centres interfected the earth's furface in a point fituated in 17° N. Lat. and 183° E. Long. from London. The axis of the magnet is perpendicular to this line, and the plane in which it lies is inclined about 11° to the plane of the meridian, the north end of the axis lying on the eaft fide of that meridian.

 From

From these data, it will be found that the axis of this magnet cuts the surface of the earth about the middle of the eastern shore of Baffin's Bay, and in another point about 800 miles S.S.W. of the southern point of New Zealand. Professor Lichtenberg of Gottingen, who gives this extract from the manuscript, says, that the hypothesis is accompanied by a considerable list of variations and dips calculated by it, and compared with observations, and that the agreement is very remarkable. He gives indeed a dozen instances in very different regions of the earth. But we suspect that there is some error or defect in the data given by him, because the annual changes, which he also gives, are such as are inconsistent with the data, and even with each other. He says, that the distance from the centre increases about four miles annually, and that *thence* arises an annual diminution of 8 minutes in the latitude and 14 in the longitude of that point where the straight line joining the centres meets the surface. It can have no such consequence. He says also, that the above mentioned inclination of the planes increases 8 minutes annually. The compound force of the magnet is said to be as the square root of the distance inversely. We are at a loss to understand the meaning of this circumstance; because Mayer's hypothesis concerning the law of magnetic action is exceedingly different, as related by Mr Lichtenberg from the same manuscript. But it was our duty to communicate this notice, though imperfect, of the speculations of this celebrated mathematician. See *Erxleben's Elem. of Nat. Phil.* published by Lichtenberg 1784, p. 645.

Addition to n° 64.

Addition to n° 64. Let HZOF (fig. 37.) be the plane of a magnetic meridian, H n' O the plane of the horizon, and NS the position of the magnetic needle in any place, when it is at liberty to settle in the true magnetic direction. The angle HON is the inclination or dip of the needle. Let Z n F be a vertical circle, in which a well constructed dipping needle can freely play up and down. This needle cannot place itself in the magnetic direction, because it can only move in a vertical plane. Its north point is impelled in the direction $n\,o$, and its south point in the direction $s\,p$, both of which are parallel to NS. By the laws of mechanical equilibrium, it cannot rest, except in such a position that the forces $n\,o$ and $s\,p$ are in a plane perpendicular to the plane Z n F. In any other position, there would be a force impelling the needle toward that side on which $n\,o$ makes an acute angle with the tangent $r\,n\,t$ of the vertical circle. Therefore the spherical triangle N n F is right angled in n, and Cos. NFn : R = Tan. n F : Tan. NF, = Tan. HN : Tan. n' n. Therefore

$$\text{Tan. } n'n = \frac{\text{Tan. HN}}{\text{Cos. H}n'}, = \text{Tan. HN} \times \text{Sec. H}n'.$$

Therefore, in any place, the real inclination of the magnetical direction to the horizon is different from what is pointed out by a dipping needle when it is in a plane which declines from the magnetic meridian; and the tangent of the observed dip of the needle exceeds that of the inclination of the magnetic direction in the proportion of radius to the cosine of the deviation HCn', or the proportion of the secant of this angle to the radius. If therefore the dipping needle play in a magnetic east and west circle, it will stand perpendicular to the horizon.

MAL

Malesherbes. MALESHERBES (Christian William de Lamoignon) was born December the 6th 1721. At the age of 24 he became a counsellor of Parliament, and six years afterwards chief president of the *cour des aides.* He remained in that important situation during a period of 25 years, and displayed on many occasions proofs of firmness, eloquence, and wisdom.

When the prince of Condé was sent by the king in 1768 to silence the magistrates who opposed the taxes, Malesherbes replied to him, "Truth, Sir, must indeed be formidable, since so many efforts are made to prevent its approach to the throne." About the same time that he became president of the *cour des aides*, he was appointed by his father, then chancellor of France, superintendant of the press; an office of the greatest importance, of which the principles which Malesherbes had imbibed from D'Alembert rendered him very ill qualified to discharge the duties. He was what the French called a *philosopher*; a term with them of the same import with a naturalist, who openly denies revealed religion, and has no adequate notions of the moral attributes of God. The consequence was, that when the authors of impious and immoral books were brought before him in his official capacity to undergo examination, he appeared to them as advising, assisting, and protecting them, against that very power which was vested in himself; and they were commonly dismissed with this senseless observation, that all books of whatever tendency should be considered merely as *objects of commerce.* Had it not been for the protecting influence of Malesherbes, the *Encyclopédie*, of which the publication was frequently suspended (see DIDEROT in this *Supplement*), would probably have been altogether suppressed; and the works of Rousseau and Raynal, which so powerfully contributed to that revolution in which he was overwhelmed, would certainly not have spread so rapidly over the kingdom of France. It was he, said D'Alembert, who *broke the shackles of literature.*

In vain will it be replied, that he left the same liberty to the religious as to the impious writers; for that was not always strictly true. The Abbé Barruel has brought the testimony of D'Alembert himself to prove, that it was much against his will that Malesherbes suffered works refuting the sophisters to appear; and, as he very properly observes, what a minister allows with reluctance, he finds abundant means of preventing.

In 1775 he resigned the office of chief president of the *cour des aides*, and was appointed minister and secretary of state in the place of La Vrillière. Thus placed in the centre of a frivolous yet brilliant court, Malesherbes did not in the least deviate from his former simplicity of life and manners; but, in lieu of complying with the established etiquette which required magistrates, when they became ministers of state, to exchange their sable habit and head dress for a coloured suit, bag-wig, and sword, he retained his black coat and magisterial *peruke!* This is recorded by a panegyrist to his honour; but we perceive not the honour which

which it reflects on him. It surely requires no great powers of abstraction to discover, that a coloured coat, bag-wig, and sword, are not in themselves more frivolous or contrary to nature, than a black coat and enormous peruke; and if the manners of a country have appropriated these different dresses to different stations in life, the individual must be actuated by a very absurd kind of pride, who sets up his own caprice against the public opinion.

As, when invested with the power to restrain within just limits the freedom of the press, it was his chief aim to encourage and extend that freedom; so, when raised to an office which gave him the unlimited power of issuing *lettres de cachet*, it was their total suppression that became the earliest object of his *most ardent* zeal. Till that time *lettres de cachet*, being considered as a part of the general police, as well as of the royal prerogative, were issued not only at the will of the minister, but even at the pleasure of a common clerk, or persons still more insignificant. Malesherbes began by relinquishing himself this absurd and iniquitous privilege. He delegated the right to a kind of tribunal, composed of the most upright magistrates, whose opinion was to be unanimous, and founded upon open and well established facts. He had but one more object to attain, and that was to substitute a legal tribunal in the place of that which he had established; and this object he was upon the point of accomplishing, when the intrigues of the court procured the dismission of Turgot; and Malesherbes, in consequence, resigned on the 12th of May 1776. For this part of his conduct he is intitled to praise, which we feel not ourselves inclined to withhold from his memory. Even M. Barruel admits, that he had many moral virtues, and that he displayed real benevolence when alleviating the rigours of imprisonment, and remedying the abuse of *lettres de cachet*; but France, says he, shall nevertheless demand of him her temples that have been destroyed; for it was he who, above all other ministers, abused his authority to establish in that kingdom the reign of impiety.

After this epoch he undertook several journeys into different parts of France, Holland, and Switzerland, where he collected with zeal and taste objects of every kind interesting to arts and sciences. As he travelled with the simplicity and economy of a man of letters, who had emerged from obscurity for the purpose of making observations and acquiring knowledge, he by that means was enabled to reserve his fortune for important occasions, in which it might procure him information on interesting subjects. He travelled slowly, and frequently on foot, that his observations might be the more minute; and employed part of his time in suitably arranging them. These observations formed a valuable collection of interesting matter relative to the arts and sciences, but which has been almost totally destroyed by the fury of revolutionists, who have done as much prejudice to the interests of science as of humanity.

Returning from his travels, Malesherbes for several years enjoyed a philosophic leisure, which he well knew how to direct to useful and important objects. The two treatises which he composed in the years 1785 and 1786 on the civil state of the protestants in France are well known. The law which he proposed in these, was only preparatory to a more extensive reform; and these treatises were to have been followed up by another work, the plan of which he had already laid down, when affairs growing too difficult to be managed by those who held the reins of government, they were compelled to call him to their councils. They did not, however, assign him the direction of any department, and introduced him merely (as subsequent events have shewn) to cover their transactions under a popular name, and pass them on the world as acts in which he had taken part. Malesherbes accepted their overtures merely to satisfy the desire he felt to reveal some useful truths; but it was not for that purpose that they had invited him to their councils. Those who presided at them took umbrage at his first efforts to call their attention to the voice of truth and wisdom; and succeeded so well in their opposition, that he was reduced to the necessity of delivering in writing the counsel which he wished to offer. Such was the origin of two treatises relative to the calamities of France, and the means of repairing them. He transmitted these treatises to the king, who never read them; nor was he ever able to obtain a private audience although a minister of state.

Such is the account of his last conduct in office which is given by his friends; and as we have not read his treatises on the calamities of France, we have no right to controvert it. From his known principles, however, we are intitled to conclude, that his plans of reformation were similar to those of Neckar, the offspring rather of a head teeming with visionary theories, than of the enlightened mind of a practical statesman, or the corrupt heart of a Jacobin conspirator.

Perceiving the inutility of his endeavours, disgusted with what he thought the repeated errors of the government, and deprived of every means of exposing them, or preventing their fatal effects; after frequent solicitations, he at length obtained leave to retire. He repaired to his estate at Malesherbes, and from that moment entirely devoted his time to those occupations that had ever formed the chief pleasure of his life. He passed the evenings and a great part of the night in reading and study.

In this tranquil state he was passing the evening of his days amidst his woods and fields, when the horrors of the Revolution brought him again to Paris. During the whole of its progress, he had his eyes constantly fixed on his unhappy sovereign, and, subduing his natural fondness of retirement, went regularly to court every Sunday, to give him proofs of his respect and attachment. He imposed it as a duty on himself to give the ministers regular information of the designs of the regicide faction *; and when it was determined to bring the king to trial, he voluntarily offered to be the defender of his master, in his memorable letter of the 11th of December 1792, that eternal monument of his loyalty and affection. His offer was accepted; and he pleaded the cause of the monarch with a strength of argument that nothing could have resisted but the bloodthirsty minds of a den of Jacobins. "What Frenchman (says a valuable writer), what virtuous man, of any country, can ever forget that affecting scene, when the respectable old man, penetrating, for the first time, into the prison of the Temple, melted into tears, on finding himself pressed in the arms of his king; and that still more affecting scene, when, entrusted with the most agonizing commission that a subject could possibly have to his sovereign, he threw himself at the feet of the innocent victim, while, suffocated with his sobs, his voice,

Malesherbes.

till re-animated by the courage of the virtuous Louis, was inadequate to announce the fatal sentence of death *.

Having discharged this painful and hazardous duty he once more returned to his country residence, and resumed his tranquil course of life. But this tranquillity was of short duration. About a twelvemonth afterwards, in the month of December 1793, the new-created members of the Revolutionary Committee of Paris came to reside with him, his son-in law, and his daughter, and apprehended the two latter as criminals. Left alone with his grandchildren, Malesherbes endeavoured to console the rest of his unfortunate family with the hopes which he himself was far from entertaining, when, the next day, the new formed guards arrived to apprehend him, and the whole of his family, even the youngest infants. This circumstance spread a general consternation throughout the whole department; for there was hardly a man in France, a few excepted, who did not revere the mild virtues of the last friend of the unfortunate king.

In this calamity Malesherbes preserved the undisturbed equanimity of virtue. His affability and good humour never forsook him, and his conversation was as usual, so that to have beheld him (without noticing his wretched guards), it seemed that he was travelling for his pleasure with his neighbours and friends. He was conducted the same night to the prison of the Madelonette with his grandson Louis Lepelletier, at the same time that his other grandchildren were separated into different prisons. This separation proving extremely afflicting to him, he earnestly solicited against it; and at length, on his repeated entreaties, they all met together once more at Port-Libre. They remained there but a short period. The son in-law of Malesherbes, the virtuous Lepelletier Rasambo, the first of them who was arrested, was ordered into another prison, and sacrificed a few days after. Malesherbes himself, his daughter, his grand-daughter, and her husband, were soon after all brought to the guillotine. They approached it with fortitude and serenity. It was then that his daughter addressed these pathetic words to Mademoiselle Sombreuil, who had saved the life of her own father on the 2d of September: "You have had the exalted honour to preserve *your* father—I have, at least, the consolation to die with *mine*."

Malesherbes, still the same, even to his last moments exhibited to his relations an example of fortitude. He conversed with the persons that were near him without bestowing the least attention on the brutalities of the wretches who tied his hands. As he was leaving the prison to ascend the fatal cart, he stumbled against a stone, and made a false step. "See (said he smiling), how bad an omen! A Roman in my situation would have been sent back again." He passed through Paris, ascended the scaffold, and submitted to death with the same unshaken courage. He died at the age of 72 years, 4 months, and 15 days. He had only two daughters, and the son of one of them alone remains to succeed. From this account of Malesherbes's behaviour at his last moments, we are inclined to believe that his intentions were better than some parts of his practical conduct; and we know, that having dispelled the vain illusions of philosophism, he acknowledged his past errors; exclaiming, in the accents of grief, "That false philosophy (to which I confess I was myself a dupe) has plunged us into the gulph of destruction, and, by an inconceivable magic, has fascinated the eyes of the nation, and made us sacrifice reality to a mere phantom. For the simple words *political liberty*, France has lost that *social freedom* which she possessed in every respect, in a higher degree, than any other nation! How truly great did the king appear in his last moments! All their efforts to degrade him were vain; his unshaken virtue triumphed over their wickedness. It is true, then, that religion alone transfuses sufficient courage into the mind of man, to enable him to support, with so much dignity, such dreadful trials †.

Malguzzary. Malphaghino.

MALGUZZARY, in the language of Bengal, *payment* of revenue; the *revenue* itself.

MALPHAGHINO (John), otherwise called John de Ravenna, from the place of his birth, was born in the year 1352, of a family distinguished neither by riches nor nobility. His father, however, committed him to the care of Donatus the grammarian, an intimate friend of Petrarch, who at that time taught the Latin tongue with great applause at Venice. Donatus thought he discovered such happy dispositions in young Malphaghino, that he recommended him to Petrarch, not only as an excellent assistant to facilitate his labours, by reading or transcribing for him, but as a youth of the most promising talents, and worthy of being formed under the inspection of the greatest man of the fourteenth century.

It appears from some of Petrarch's letters, for it is from these chiefly we can obtain information respecting John de Ravenna, that he fully answered the expectations formed of him; and that he even gained the favour and affection of his patron so much, that he loved him and treated him as if he had been his own son. In a letter to John de Certaldo (A), Petrarch highly extols him, not only for his genius and talents, but also for his prudent and virtuous conduct. "He possesses (says he) what is very rare in our times, a great turn for poetry, and a noble desire to become acquainted with every useful and ornamental part of knowledge. He is favoured by the Muses, and already attempts verses of his own; from which one can foretel, that, if his life be spared, and if he goes on as hitherto, something great may be expected from him."

Not long, however, after this panegyric was written, young Malphaghino conceived an insuperable desire to see the world; and, notwithstanding all Petrarch's remonstrances, persisted in his resolution of quitting him. Petrarch's paternal care and regard for his pupil appear, on this occasion, in the most favourable light, as may be seen in his letters to Donatus; and his whole behaviour, though the young man insisted on leaving him, without assigning a sufficient reason for his precipitate and ungrateful conduct, does as much honour to his head as to his heart.

The precipitation with which John de Ravenna carried his plan into execution was not likely to make it answer his expectations. He departed without taking with him letters of recommendation which Petrarch offered him to his friends. He, however, pursued his journey over the Appenines, amidst continual rain, giving out that he had been dismissed by Petrarch; but, though he experienced from many a compassion to which he was not entitled by his conduct he now began to awaken from his dream. He proceeded therefore to Pisa.

(A) Better known under the name of *Boccaccio* or *Boccace*. Certaldo was the place of his birth.

Pisa, in order to procure a vessel to carry him back to Pavia: but being disappointed, while his money wasted as much as his patience decreased, he suddenly resolved to travel back across the Appenines. When he descended into the Ligurian plains, he attempted to wade through a river in the district of Parma, which was much swelled by the rains; and being carried by the force of the stream into a whirlpool, he would have lost his life, had he not been saved by some people who were accidentally passing that way. After escaping this danger, he arrived, pennyless and famished, at the house of his former patron, who happened then not to be at home; but he was received and kindly entertained by his servants till their master returned.

Petrarch, by his intreaties and paternal admonitions, retained the young man at his house for about a year, and prevented him from engaging in any more romantic adventures; but, at the end of that period, his desire for rambling again returned; and as Petrarch found that all attempts to check him would be fruitless, he gave him letters of recommendation to two of his friends, Hugo de St Severino and Franciscus Brunus, at Rome. To the former of these, Petrarch says, "This youth of rare talents, but still a youth, after proposing to himself various plans, has at length embraced the noblest; and as he once travelled, he is now desirous of doing so again, in order to gratify his thirst of knowledge. He has, in particular, a strong inclination for the Greek language; and entertains a wish which Cato first conceived in his old age. This wish I have endeavoured for some years to subdue; sometimes by intreaties, at other times by admonition; sometimes by representing how much he is still deficient in the Roman language; and sometimes by laying before him the difficulties which must attend him in his journey, especially as he once before left me, and by want was obliged to return. As long as that unfortunate excursion was fresh in his memory he remained quiet, and gave me hopes that his restless spirit could be overcome and restrained. But now, since the remembrance of his misfortunes is almost obliterated, he again sighs after the world; and can be retained neither by force nor persuasion. Excited by a desire which betrays more ardour than prudence, he is resolved to leave his country, friends, and relations, his aged father, and me whom he loved as a father, and whose company he preferred to a residence at home, and to hasten to you whom he knows only by name. This precipitation even has an appearance of prudence. The young man first wished to visit Constantinople; but when I told him that Greece, at present, is as poor as it was formerly rich in learning, he gave credit to my assertion, and at any rate altered his plan, which he could not carry into execution. He is now desirous of traversing Calabria, and the whole coast of Italy, distinguished formerly by the name of Magna Graecia, because I once told him that there were in that quarter several men well skilled in the Greek language, particularly a monk, Barlaam, and one Leo, or Leontius with whom I was intimately acquainted, and of whom the first had been some time my scholar. In consequence of this proposal, he begged me to give him a recommendatory letter to you, as you have considerable influence in that part of the country. This request I granted, in hopes that the young man, by his genius and talents, will afford you satisfaction equal to the service which you may render to him." In his letter to Brunus, Petrarch expresses himself as follows: "He is a young man who wishes to see the world as I formerly did; but I never reflect on it without horror. He is desirous of seeing Rome; and this desire I cannot condemn, as I myself have so often visited that city, and could still revisit it with pleasure. I suspect, however, that he will venture on a more extensive ocean, and that he imagines to find a fortune where he will, perhaps, meet with a shipwreck. At any rate, he is desirous, he says, of putting his fortune to a trial. I wish it may be favourable; should it be adverse, he is still at liberty to return to my peaceful, though small, haven; for I hang out a light, during the day as well as the night, to guide those who quit me through youthful folly, and to enable them to find their way back. The ardour by which he is impelled must not be ascribed so much to him as to his age, and is in itself commendable. If I am not much deceived, the young man loves me and virtue in general. He is unsteady, but modest; and deserves that all good men should contribute to his prosperity as far as they can."

From the letters of Petrarch, there is reason to believe, that John de Ravenna lived with him only about three years in all; and that he had not attained to the full age of manhood when he left him. It appears also, for this circumstance is very obscure, that after he quitted him, he wandered about a considerable time before he was so fortunate as to meet with a protector and patron, at whose house, as he wrote to Petrarch, he at last found a permanent asylum. How long he remained with his patron, whom some believe to have been Cardinal Philip, and what happened to him till the death of Petrarch in 1374, and for some years after, is unknown. The literary monuments of the fourteenth and fifteenth centuries say nothing farther of him till his appearance at Padua; where, according to the testimony of Sicco (B), one of the most celebrated of his scholars, he not only taught the Roman Eloquence, but also the science of moral philosophy, with such success and applause, and improved his scholars so much by his life and example, that, according to universal opinion, he far excelled all the professors of those sciences who had ever before appeared. That he was here of considerable service in reviving the study of the Latin language, and of the works of the ancient Romans, was acknowledged by all his scholars, and is confirmed by the following testimony of Blondus (C).

"About the same period, Ravenna produced that

Malphag-hino.

learned grammarian and rhetorician Johannes, of whom Leonardus Aretinus uſed to ſay, that he firſt introduced into Italy, after a long period of barbariſm, the ſtudy of the Latin language and eloquence, now ſo flouriſhing; a circumſtance which deſerves to be enlarged on in the preſent work. Thoſe well acquainted with Roman literature know, that after the periods of Ambroſe, Jerom, and Auguſtine, there were none, or very few, who wrote with any elegance, unleſs we add to theſe good writers, St Gregory, the venerable Bede, and St Bernard. Francis Petrarcha was the firſt who, with much genius, and ſtill greater care, recalled from the duſt the true art of poetry and of eloquence. He did not attain to the flowers of Ciceronian eloquence, with which many are adorned in the preſent century; but this was owing rather to a want of books than of talents. Though he boaſted of having found at Vercelli Cicero's letters to Lentulus, he was unacquainted with the books of that great Roman *De Oratore*, Quintilian's Inſtitutes, the *Orator*, the *Brutus*, and other writings of Cicero. John de Ravenna was known to Petrarch both in his youth and in his old age. He was not more converſant with the ancients than Petrarch; and, as far as I know, left no works behind him. By his excellent genius, however, and, as Leonardus Aretinus ſays, by the particular diſpenſation of God, he was the preceptor of this Leonardus, of Petrus Paulus Vergerius, of Annebonus de Padua, of Robert Roſſi, of James Angeli of Florence, of Poggius and Guarino of Verona, of Victorinus, Sicco, and other men of leſs note, whom he incited to the ſtudy of better knowledge, and to imitate Cicero, if he could not form them or inſtruct them completely.

"About the ſame time, Manuel Chryſoloras, a man as virtuous as learned, came from Conſtantinople to Italy, and inſtructed in the Greek language, partly at Venice and partly at Florence and Rome, all the before mentioned ſcholars of John de Ravenna. After he had continued this inſtruction for ſome years, thoſe unacquainted with the Greek language, and the ancient Greek writers, were conſidered in Italy as more ignorant than thoſe unacquainted with the Latin. A great many young men and youths were inflamed with an enthuſiaſtic deſire for the works of the ancient Greeks and Romans. At the time of the council of Conſtance, in the beginning of the fifteenth century, many of my countrymen endeavoured, by ſearching the neighbouring cities and convents, to diſcover ſome of the Roman manuſcripts which had been loſt. Poggius firſt diſcovered a complete copy of Quintilian, which was ſoon followed by the letters of Cicero to Atticus. As our youth applied to the ſtudy of theſe works with the utmoſt diligence, that celebrated grammarian and rhetorician Caſparinus de Bergamo, opened a ſchool at Venice, ſuperior to the former, and in which young perſons were encouraged to ſtudy the ancient languages and writers. About the ſame time flouriſhed Petrus Paulus Vergerus, Leonerdus Aretinus, Robert Roſſi, James Angeli, Poggius, and Nicolaus de Medici, whom Aretin had long inſtructed. Guarinus alſo had begun to inſtruct many at Venice, and Victorinus at Mantua, when Philip III. Duke of Milan, recalled Caſparinus as his ſubject, from Venice to Padua and Milan. The increaſing ſtudy of ancient literature was much promoted by Gerard Landriano biſhop of Lodi, diſcovering under ſome ruins an old copy of Cicero, written in characters ſcarcely legible, which, among other rhetorical writings of that great Roman, contained the whole books *De Oratore*, with his *Brutus* and *Orator*. This ſaved Caſparinus the trouble of ſupplying the books of Cicero *De Oratore*, as he had attempted to ſupply the works of Quintilian. As no one was found in all Milan who could read this old manuſcript of Cicero, an ingenious young man of Verona, named Caſmus, was ſo fortunate as firſt to tranſcribe the books *De Oratore*, and to fill all Italy with copies of a work which was univerſally ſought for with the utmoſt avidity. I myſelf, in my youth, when I went to Milan on the buſineſs of my native city, tranſcribed, with as much ardour as ſpeed, the *Brutus* of Cicero, and ſent copies of my tranſcription to Guarinus at Verona, and to Leonard Juſtiniani at Venice; by which means this work was ſoon diſperſed all over Italy. By theſe new works eloquence acquired new fire; and hence it happens, that in our age people ſpeak and write better than in the time of Petrarch. The ſtudy of the Greek language, beſides the abundance of new and uſeful knowledge which it diſcloſed, was attended with this great advantage, that many attempted to tranſlate Greek works into Latin, and thereby improved their ſtyle much more than they could have done without that practice. After this period, ſchools for teaching the ancient languages increaſed in Italy, and flouriſhed more and more. Moſt cities had ſchools of this kind; and it gives one pleaſure to obſerve, that the ſcholars excelled their maſters, not only when they left them, but even while they were under their tuition. Of the ſcholars of John de Ravenna, two of the oldeſt, Guarinus and Victorinus, the former at Venice, and the latter at Mantua, Verona, Florence, and Ferrara, inſtructed an immenſe number of pupils; and among theſe, the Princes of Ferrara and Mantua. George of Trebiſonde, when he lectured at Rome, had for his auditors, beſides Italians, many French, Spaniards, and Germans, among whom ſometimes there were men of rank and eminence. Franciſcus Philelphus, who had been taught at Conſtantinople by Chryſoloras himſelf, inſtructed a great many young men and youths in the Greek and Latin languages at Venice, Florence, Siena, Bologna, and, laſt of all, at Milan." In the above quotation, the ſhare which John de Ravenna had in reviving and diffuſing a knowledge, not only of the Roman, but alſo of the Grecian literature, is ſo clearly repreſented, that no farther teſtimony is neceſſary to eſtabliſh his claim to celebrity.

After John de Ravenna had taught at Padua, he removed for the like purpoſe to Florence; where, as appears, he inſtructed young people for ſome time, without being expreſsly invited by the government, and without being publicly paid for his labours. In the beginning of his reſidence at Florence, he ſeems to have been recommended by Colucius to the learned Charles de Malateſta. "There lives here at preſent (ſays Colucius, in one of his letters) a teacher of great merit, John de Ravenna.—He is (continues he) of mature age; irreproachable in his manners, and ſo diſpoſed in general, that if you receive him, as I hope and wiſh, among the number of your intimate friends, you will find him an agreeable and incomparable aſſiſtant to you in your labours and ſtudies. What can be more deſirable to you than to poſſeſs a man who will lucubrate and labour for you? and who, in a ſhort time, can communicate to you what you could not obtain by your

own exertions without great difficulty. I do not know whether you will find his like in all Italy; and I therefore wish, that, if you confide in my judgment, you will receive John de Ravenna in the room of your late learned friend James de Alegretti." It is not known whether John de Ravenna went to reside with Malatesta or not. It is, however, certain, that the former, in 1397 (the same year in which Mannel Chrysoloras came to Florence), was invited thither by the magistrates of that city, with the promise of an annual salary, to instruct young people in the Roman language and eloquence; that John de Ravenna, at the period when he entered into this honourable engagement, was 45 years of age; and that the scholars of John de Ravenna were, at the same time, scholars of Chrysoloras. Saluratus Colucius, in all probability, was the cause of this invitation, as he was acquainted with the services of John de Ravenna, and knew how to appreciate them. "We know (says he, in one of his letters to John de Ravenna), and all who respect you know also, that none of the moderns, or even ancients, approached so near to Cicero as you; and that to the most wonderful beauty and powers of speech, you join the deepest knowledge." John de Ravenna, like Chrysoloras, and most of the teachers of the Greek and Roman languages in the beginning of the fifteen century, was, no doubt, engaged at first only for a few years; when these were elapsed, the engagement was renewed, perhaps for the last time, in 1412, and he was bound, besides teaching the Roman eloquence, to read publicly, and explain in the cathedral, on festivals, the poems of Dante. John de Ravenna did not long survive the above renewal of his engagement; for an anonymous writer, who, in 1420, finished *A Guide to Letter-writing, according to the Principles of John de Ravenna*," speaks of his preceptor as of a man not then in existence.

MALT. See BREWING (*Encycl.*), where a full account is given of Sir Robert Murray's method of malt-making, together with some valuable observations on malt by Mr Richardson of Hull. In a late edition of this latter gentleman's *Theoretic Hints on Brewing*, we are told, that Mr Edward Rigby of Norwich is of opinion, that the mere exsiccation of corn is not the only object obtainable by drying it on the kiln, but that some portion of the saccharum of malt is the effect of that process. "The operation of kiln-drying the malt (says Mr Rigby) is as follows:—The grain is spread thick upon a floor made of flat bricks (*tiles*), or iron plates, which are full of perforations; immediately under this floor is the oven or furnace, in which is a large fire made of *coaks*, cinders, or, in some places, billet wood; a current of air, at the mouth of the furnace, keeps up the combustion of the coaks, and the air which is phlogisticated by their burning, and which, in a common fire place, rises up the chimney, passes, in this instance, through the apertures in the floor, and penetrates the whole stratum of malt before it can pass into the external air. Under these circumstances, it is evident, that the interstices of the malt must be filled with phlogistic air; and as the grain usually remains in this situation about two days, it is obvious, that if it have the power of absorbing phlogiston, it certainly must do it when so long in contact with it. And that the malt does really imbibe some of this principle, is not only probable on the general ground of the truth of the preceding theory, but, I believe, it will be found, that the phlogisticated air which rises from the burning substances underneath, is corrected in passing through the malt; for without its being meliorated by this or some other cause, it is evident that the air in the kiln-chamber, more especially the lower strata of it, must be noxious, and probably even so much so as to be unfit for respiration and combustion. But so far from this being the case, I am informed, that workmen will lie and sleep many hours on the malt in this situation without suffering any inconvenience. And after mentioning this, it is scarcely necessary to add, that I find also, by experiment, that a candle will burn perfectly well in the air which is immediately on the surface of the malt.

"Were heat alone sufficient for the purpose of completing the operation of malting, it certainly might be applied in a much more cheap way than is at present done; for the floor on which the grain is laid might, unquestionably, be heated equally without there being perforations in it, as with them. In which case, one kind of fuel would be as good as another; and, consequently, the present expence of previously burning the coals, to convert them into coaks or cinders, might be saved.

"But, admitting that the application of phlogiston to the malt, as well as heat, is requisite in this operation, the necessity of these perforations becomes evident, and also the propriety of previously burning the coals in such a way, that all the water, and those other heterogeneous particles which compose smoke and soot, may be dissipated; for these, merely as such, would obviously contribute little to the phlogistication of the malt, and would evidently impart some offensive flavour, if not some obnoxious quality to it.

"Reasoning from the above premises (Mr Rigby concludes), it would seem, that as all the farinaceous parts of the barley are seldom dissolved in brewing, and the grains which are left have usually the disposition to become sour, thereby manifesting some of the acid principle to be still existing in them, it is not improbable but some further saccharine matter might be obtained from the grain by another exposure to phlogisticated air, or, in other words, by being once more laid on the kiln."

This is indeed so far from being improbable, that we think it must infallibly be the case. Sugar, it is well known, consists of oxygen, hydrogen, and carbon (see CHEMISTRY in this *Supplement*, n° 466.); but from the disposition of the grains to become sour, it is plain, that after the process of brewing they still retain much oxygen; and the azotic gas, which is here called phlogisticated air, there is every reason to believe contains both hydrogen and carbon. These, therefore, uniting with the oxygen of the grains, must make an addition to the saccharine matter. This has, indeed, been found to be the fact by Mr Richardson, who, in consequence of Mr Rigby's suggestion, was induced to brew a small brewing of malt, of ten quarters only, and stopping the process when, according to his general practice, one extract was still due, he ordered the grains to be laid upon one of his malt-kilns, and cinders to be applied the same as for drying of malt. This was continued for two days and a half, when the grains, being perfectly dried, were put into sacks, and, when cold, returned again into the mash-tun. The event, in some measure, justified Mr

Mammalukes.

Rigby's expectation; for the produce of fermentable matter was considerably more than he had reason to expect, than would have been the case, had the extract been made in immediate succession, as it would have been in the ordinary course of his practice. He attempts, indeed, to account for it in a way very different from ours; but though we have the highest confidence in Mr Richardson as an experienced brewer, we must sometimes beg leave to think for ourselves as chemists. Like a man of sense, however, and a man of science, he says, "I am so well satisfied with the event of this experiment, that I shall probably be inclined, on some future occasion, to repeat it, in various stages of the process. The fine lively froth on the surface of the wort, in the underback, added to its transparency and good flavour, are circumstances which induce me to thank Mr Rigby for the hint, which, it is not improbable, may be applied to some useful purpose, in certain situations which sometimes occur in the brewing trade."

MAMMALUKES, MAMALUCS, *Mamelouces*, or *Mamluks*, were a dynasty that reigned for a considerable time in EGYPT, and of which some account has been given in that article (*Encycl.*). A fuller account of them must, however, be acceptable to our readers, as, since the expedition of Buonaparte, they have attracted the attention of all Europe.

They were first introduced into Egypt, as we have already observed, by Saladine, who, when he had it in contemplation to besiege Jerusalem, very naturally endeavoured to collect the most forcible means to accomplish so desirable an end; and, in consequence, observing that the ancient inhabitants of Egypt were, from their effeminate mode of education, and the quiet and tranquil habits of their lives, much fitter for those occupations in which they delighted, namely, the arts, merchandize, and mechanics, than military tactics and military toil, he resolved, as little as possible, to employ or depend upon them.

This resolution stimulating him to procure a hardier race of soldiers he therefore commissioned agents to treat with the Circassians, by the Lake of Mæotis, near Tawrica Chersonesus, whence, about the year 1176, they purchased more than a thousand slaves. Men inured to hardship, nurtured in the lap of toil and danger, and bred from their infancy to war, which was to them rather an instinct than a science, as the continual incursions of the Tartars rendered self defence, in their situation, absolutely necessary.

These slaves Saladine trained to military discipline, and, at the same time that he made them renounce Christianity, had them instructed in the Mahometan religion; and although he prohibited them from marrying, he allowed them an unbounded licence with respect to desultory gallantry. What progress they made in the doctrines of the Alcoran, whether the tenets of that sacred volume effectually eradicated all their first principles, is uncertain; but it is certain, that in time they became excellent soldiers, and that the military glory of Saladine, which was feebly supported by the native Egyptians, expanded in the hands of the Mamelouces, who extended their conquests on every side, until, pervading the Holy Land, they entered in the plain of Askelon.

These Mamelouces, who were continually adding to their numbers, in process of time became naturalized to the country; and, as it has been observed, they excelled the Egyptians in strength of body, in military discipline, in their skill in horsemanship, and in courage; so they, by the liberality of their generals, and the plunder of cities and provinces, also excelled them in wealth. In fact, their mode of education fitted them for the most dangerous and adventurous enterprises, and, from being the slaves, enabled them in time to become the masters of even the Turks, by whom they had originally been purchased.

After the death of Saladine, who left the kingdom to his brother, they rose to still greater importance than they had acquired during his reign, and continued, if not absolutely to govern, yet, like the Roman soldiers in the time of Pertinax, Alexander, and Valerian, to awe the monarch.

This influence continued through the reigns of five successive Caliphs, until that of Melachsala, the last of the posterity of Saladine, who being at war with the Arristians, and, at the same time, wishing to repress the enormous power of the Mamelouces, purchased slaves from all the surrounding countries, whom, in imitation of his ancestor, he armed and appointed to defend his dominions. The event of this measure was exactly what might have been expected. Melachsala was, in consequence of a conspiracy betwixt his new and his old soldiers, slain; and Turquemenus, the leader of this mutiny and rebellion, hailed by the title of Great Sultan of Egypt. With him began the government of the Mamelouces, about the year 1250; which had the next year gathered such strength, that it was thought necessary, in order to repress those exuberances to which new formed governments are liable, and bring it nearer to a system, to cause the following articles, in the form of a charter, to be subscribed to by their principal leaders, as an act of the whole people:—"1st, That the Soltan should be chosen from the body of Mamelouces; 2dly, That none should be admitted into the order that were by birth either Jews or Turks, but only Christian captives; 3dly, That the native Egyptians should not be permitted to use, or have, any weapons, except the instruments of agriculture."

Turquemenus, as is frequently the practice with those that experience a sudden elevation, endeavoured to kick down the ladder by which he had been raised; or, in other words, his carriage was so haughty and disdainful to his former companions, that he was by them, or rather by one of them named Clotho, suddenly slain; for which the murderer was rewarded with his sceptre. After him succeeded a long race of princes, many of whom were as eminent for their talents as for their valour; among whom, the name of Caitbeius has been transmitted to us as that of the greatest statesman and general of his age; but, as every one who considers the *materials* of which the government was composed, must rather wonder that it existed so long, than that it should, through almost the whole course of its operation, be exposed to all the various evils and distresses arising from a long train of sedition and tumults, so he must lament that it should expire in the reign of one of their wisest and best monarchs: yet it is some consolation to reflect, that Campson, the last Sultan of the Mamelouces, was not *murdered by his own subjects*, but having for many years governed the kingdoms of Egypt, Judea, and Syria, in a manner that has excited the praise of

Mamma-lukes.

of the hiſtoric pen, he, oppreſſed with age and diſeaſe, and encumbered with his armour, ſunk upon the field of battle, and, with his laſt breath, yielded the victory to the fortunate Selim.

With this monarch, who expired January 20, 1516, [illegible] the government of the Mamelouces, after it had continued 276 years; for although an attempt was made by Tomumby to get himſelf declared Sultan, in which attempt he actually ſucceeded ſo far as to be inveſted with the title, yet he was ſoon after defeated by the victorious Selim. He was then forſaken by his troops, taken and executed; while the Mamelouces, broken and diſperſed, it was the policy of Selim to rally, and, by offers too tempting to be by them refuſed, engage in his ſervice. The uſe of theſe ſoldiers ſoon became ſufficiently apparent to the Turkiſh Emperors, to ſtimulate them to augment their number, enlarge their ſphere of action, and combine them cloſer to the ſtate, by the allowance of ſtill greater privileges and advantages than they had before enjoyed.

The Beys were ordained to be choſen from among them; and the Paſha, or chief governor for the Porte, was to ſhare his power with thoſe Beys, and even to continue in office no longer than ſhould be agreeable to their collective will. At firſt the power of the Paſha was very extenſive; but, by the intrigues and ambition of the Beys, it has been reduced almoſt to a cypher. It was rather of a civil than military nature. He was always preſident of the Divan, which was held in the caſtle where he reſided. But that council now commonly meets in the palace of one of the chief Beys, except when a firman or mandate is received from Conſtantinople, when the Beys are ſummoned to the caſtle, to hear the commands of the Porte. The few who attend, as ſoon as the reading is finiſhed, anſwer, as is uſual, "*Eſmana wa taana*," "We have heard, and we obey." On leaving the caſtle, their general voice is "*Eſmana wa aaſina*," "We have heard, and ſhall diſobey."

In the year 1791, Salah Aga, a ſlave of Murad Bey, was deputed from the government of Egypt to negociate their peace with the Porte. He carried preſents of horſes, rich ſtuffs, &c. A ſpontaneous tribute, which the Porte was in no condition to enforce, implied obligation on the part of the latter. He was well received, and afterwards was appointed *Waquil es Sultan*, agent or attorney to the Sultan in Cairo. It is probable, this office was given him to incline him to ſecond the efforts of the Court in diſuniting the Beys; but it was ineffectual. Theſe had formerly experienced the evils of diviſion, and now were united by common intereſt, grown rich, and well provided with ſlaves; ſo that no tribute has ſince that time found its way to Conſtantinople.

The Mamelouces remain, as they have ever been, military ſlaves, imported from Georgia, Circaſſia, and Mingrelia. A few have been priſoners, taken from the Auſtrians and Ruſſians, who have exchanged their religion for an eſtabliſhment. The Beys give general orders to their agents at Conſtantinople, to purchaſe a certain number every year; and many are brought to Egypt by private merchants on ſpeculation. When the ſupply proves inſufficient, or many have been expended, black ſlaves from the interior of Africa are ſubſtituted, and, if found docile, are armed and accoutred like the reſt.

Particular attention is paid to the education of theſe favoured ſlaves. They are inſtructed in every exerciſe of agility or ſtrength, and are, in general, diſtinguiſhed by the grace and beauty of their perſons. The gratitude of the diſciples is equal to the favour of their maſters, whom they never quit in the hour of danger. If they have a diſpoſition for learning, they are taught the uſe of letters, and ſome of them are excellent ſcribes; but the greater part neither can read nor write. A ſtriking example of which deficiency is obſervable in Murad Bey himſelf.

The inferior Mamelouces conſtantly appear in the military dreſs, and are commonly armed with a pair of piſtols, a ſabre, and a dagger. They wear a peculiar cap of a greeniſh hue, around which is wreathed a turban. The reſt of their dreſs reſembles that of other Mohamedan citizens, and is reſtricted to no particular colour; but another ſingularity is, their large drawers of thick Venetian cloth, of a crimſon colour, to which are attached their ſlippers of red leather. On horſeback they add to their arms a pair of large horſe piſtols, and the dubbus or battle-axe. In battle, many of them wear an open helmet, and the ancient ring armour of interwoven links of ſteel, worn under part of their dreſs, and thus concealed. Theſe are dear; ſometimes coſting 500 piaſtres, or about L. 50. Some of them are made at Conſtantinople, others in Perſia. Their horſes are of the fineſt Arabian breed, and are often purchaſed at three or four purſes, L. 150 to L. 200 ſterling.

They have no pay, as they eat at a table in the houſe of their maſter the Bey, Caſhef, or other officer. Any military officer may purchaſe a ſlave, who becomes, *ipſo facto*, a Mamelouc. The name, from *malk*, to poſſeſs, implies merely a perſon who is the property of another. After a proper education, the candidate thus conſtituted a Mamelouc, receives a preſent of a horſe and arms from his maſter, together with a ſuit of clothes; which is renewed every year in the month Ramadan. The generoſity of their maſters, and rewards or extortions from others, afford them ſupplies of money, either for avarice or debauchery. Some of them, admitted to peculiar favour by the Beys, as chaſnadars, or purſe-bearers, &c. acquire great wealth. They are rather gay and thoughtleſs than inſolent, fond of ſhow, and unprincipled in their means of acquiring it. They ſeldom marry till they acquire ſome office.

Though born of Chriſtian parents, they ſeem highly ſatisfied with their condition, which they have been known to refuſe to exchange for freedom. The majority are regarded by the Arabs as little ſtrict in the principles or duties of Mohamediſm. It is worthy of remark, that though the Mamelouces, in general, be ſtrong and perſonable men, yet the few who marry very ſeldom have children. As the ſon, even of a Bey, is not honoured with any particular conſideration, the women, perhaps, procure abortions. Of eighteen Beys, with whoſe hiſtory Mr Browne was well acquainted, two only had any children living.

Hardy, capable of every fatigue, of undaunted courage, and eminent ſkill in horſemanſhip and the uſe of the ſabre, the Mamelouces may be regarded as by far the beſt troops in the Eaſt. But in a regular battle, conducted by manœuvres, and large or rapid movements, they are equally inferior to European troops.

Mamma-luke-, Man.

Being distinguished by favouritism or merit, the Mameluke becomes a Cashef, and in time a Bey. The chief cause of preference arises from political adherence to some powerful leader.

The government of Cairo, and Egypt, in general, is vested in 24 Beys; each of whom is nominally chosen by the remaining 23, but, in fact, appointed by one of the most powerful. The Yenk-tchery, Aga, and several other officers, are enumerated among the 24 Beys.

Besides being governors of certain districts of Egypt, several of the Beys receive other dignities from the Porte: Such are the Shech el Bellad or governor of the city; the Defterdar, or accountant-general; the Emir el Hadj, or leader of the sacred caravan; and the Emir es Said, or governor of the Upper Egypt. These two last offices are annual. These officers have also revenues allotted them by the Porte, ill defined, and liable to much abuse.

Of the other Beys, each appoints all officers and governors within his district, putting into it some slave of his own, who is compelled to render an account of the receipts, of which a great part passes to support the grandeur of his master. An opulent Bey may have from 600 to 1000 purses annually; the revenue of Murad Bey more than doubles that sum. The inferior Beys may have 300 purses, or L. 15,000.

Every Bey sits in judgment on cases of equity. These personages are very observant of their respective jurisdictions; and no Bey will imprison a man liberated by another. Though sometimes too impetuous, they nevertheless display great acuteness and knowledge of characters. This government, at least, possesses every advantage of publicity, as every Bey is a magistrate.

MAN, has been considered in a great number of particulars under the title MAN (*Encycl.*); but a reference was made from that article to the article *Varieties of the Human Species*, which was, after all, omitted entirely.

Perhaps enough has been said on the varieties of the human species in the articles COMPLEXION and NEGRO (*Encycl.*); but as infidel ignorance is perpetually pretending, that the diminutive Icelanders, the ugly Esquimaux, the woolly-headed Negro, and the copper-coloured American, could not have descended from one original pair, either of European complexion or of Hindoo symmetry—it may not be improper, in this place, to shew the weakness of this popular objection to the Mosaic history of the origin of man. This has been done in so satisfactory a manner by Professor Blumenbach, that we have nothing to do but lay his observations before our readers, convinced, as we are, that they are intelligible to every capacity, and that they will carry conviction to all who are not the slaves of prejudice.

Phil. Mag. vol. iii. p. 284.

"Some late writers on natural history (says the Professor) seem doubtful whether the numerous distinct races of men ought to be considered as mere varieties, which have arisen from degeneration, or as so many species altogether different. The cause of this seems chiefly to be, that they took too narrow a view in their researches; selected, perhaps, two races the most different from each other possible, and, overlooking the intermediate races that formed the connecting links between them, compared these two together; or, they fixed their attention too much on man, without examining other species of animals, and comparing their varieties and degeneration with those of the human species. The first fault is, when one, for example, places together a Senegal negro and an European Adonis, and at the same time forgets that there is not one of the bodily differences of these two beings, whether hair, colour, features, &c. which does not gradually run into the same thing of the other, by such a variety of shades, that no physiologist or naturalist is able to establish a certain boundary between these gradations, and consequently between the extremes themselves.

"The second fault is, when people reason as if man were the only organised being in nature, and consider the varieties in his species to be strange and problematical, without reflecting that all these varieties are not more striking or more uncommon than those with which so many thousands of other species of organised beings degenerate, as it were, before our eyes."

As what we have said under the articles COMPLEXION and NEGRO may be sufficient to warn mankind against the first error, and at the same time to refute it, we hasten to refute the second by our author's comparison between the human race and that of swine.

"More reasons (says he) than one have induced me to make choice of swine for this comparison; but, in particular, because they have a great similarity, in many respects, to man: not, however, in the form of their entrails, as people formerly believed, and therefore studied the anatomy of the human body purposely in swine; so that, even in the last century, a celebrated dispute, which arose between the physicians of Heidelberg and those of Durlach, respecting the position of the heart in man, was determined, in consequence of orders from government, by inspecting a sow, to the great triumph of the party which really was in the wrong. Nor is it because in the time of Galen, according to repeated assertions, human flesh was said to have a taste perfectly similar to that of swine; nor because the fat, and the tanned hides of both, are very like to each other; but because both, in regard to the economy of their bodily structure, taken on the whole, shew unexpectedly, on the first view, as well as on closer examination, a very striking similitude.

"Both, for example, are domestic animals; both *omnivora*; both are dispersed throughout all the four quarters of the world; and both consequently are exposed, in numerous ways, to the principal causes of degeneration arising from climate, mode of life, nourishment, &c.; both, for the same reason, are subject to many diseases, and, what is particularly worthy of remark, to diseases rarely found among other animals than men and swine, such as the stone in the bladder; or to diseases exclusively peculiar to these two, such as the worms found in measled swine.

"Another reason (continues he) why I have made choice of swine for the present comparison is, because the degeneration and descent from the original race are far more certain in these animals, and can be better traced, than in the varieties of other domestic animals. For no naturalist, I believe, has carried his scepticism so far as to doubt the descent of the domestic swine from the wild boar; which is so much the more evident, as it is well known that wild pigs, when caught, may be easily rendered as tame and familiar as domestic swine: and the contrary also is the case; for if the latter by any accident get into the woods, they as readily become wild again; so that there are instances of such animals

animals being shot for wild swine; and it has not been till they were opened, and found castrated, that people were led to a discovery of their origin, and how, and at what time, they ran away. It is well ascertained, that, before the discovery of America by the Spaniards, swine were unknown in that quarter of the world, and that they were afterwards carried thither from Europe. All the varieties, therefore, through which this animal has since degenerated, belong, with the original European race, to one and the same species; and since no bodily difference is found in the human race, as will presently appear, either in regard to stature, colour, the form of the cranium, &c. which is not observed in the same proportion among the swine race, while no one, on that account, ever doubts that all these different kinds are merely varieties that have arisen from degeneration through the influence of climate, &c. this comparison, it is to be hoped, will silence those sceptics who have thought proper, on account of these varieties in the human race, to admit more than one species.

"With regard to stature, the Patagonians, as is well known, have afforded the greatest employment to anthropologists. The romantic tales, however, of the old travellers, who give to these inhabitants of the southern extremity of America a stature of ten feet and more, are scarcely worth notice; and even the more modest relations of later English navigators, who make their height from six to seven feet, have been doubted by other travellers, who, on the same coast, sought for such children of Enoch in vain. But we shall admit every thing said of the extraordinary size of these Patagonians by Byron, Wallis, and Carteret; the first of whom assigns to their chief, and several of his attendants, a height of not less than seven feet, as far as could be determined by the eye; the second, who asserts that he actually measured them, gives to the greater part of them from 5 feet 10 inches to 6 feet; to some 6 feet 5 inches, and 6 feet 6; but to the tallest, 6 feet 7 inches: and this account is confirmed by the last-mentioned of the above circumnavigators. Now, allowing this to be the case, it is not near such an excess of stature as that observed in many parts of America among the swine, originally carried thither from Europe; and of these I shall mention in particular those of Cuba, which are more than double the size of the original stock in Europe.

"The natives of Guinea, Madagascar, New Holland, New Guinea, &c. are black; many American tribes are reddish brown, and the Europeans are white. An equal difference is observed among swine in different countries. In Piedmont, for example, they are black. When I passed (says our author) through that country, during the great fair for swine at Salenge, I did not see a single one of any other colour. In Bavaria, they are reddish brown; in Normandy, they are all white.

"Human hair is, indeed, somewhat different from swine's bristles; yet, in the present point of view, they may be compared with each other. Fair hair is soft, and of a silky texture; black hair is coarser, and among several tribes, such as the Abyssinians, Negroes, and the inhabitants of New Holland, it is woolly, and most so among the Hottentots. In the like manner, among the white swine in Normandy, as I was assured by an incomparable observer, Sulzer of Ronneburg, the hair on the whole body is longer and softer than among other swine; and even the bristles on the back are very little different, but lie flat, and are only longer than the hair on the other parts of the body. They cannot, therefore, be employed by the brush-makers. The difference between the hair of the wild boar and the domestic swine, particularly in regard to the softer part between the strong bristles, is, as is well known, still greater.

"The whole difference between the cranium of a Negro and that of an European, is not in the least degree greater than that equally striking difference which exists between the cranium of the wild boar and that of the domestic swine. Those who have not observed this in the animals themselves, need only to cast their eye on the figure which Daubenton has given of both.

"I shall pass over (says our author) less national varieties which may be found among swine as well as among men, and only mention, that I have been assured by Mr Sulzer, that the peculiarity of having the bone of the leg remarkably long, as is the case among the Hindoos, has been remarked with regard to the swine in Normandy. 'They stand very long on their hind legs (says he, in one of his letters); their back, therefore, is highest at the rump, forming a kind of inclined plane; and the head proceeds in the same direction, so that the snout is not far from the ground.' I shall here add, that the swine, in some countries, have degenerated into races which in singularity far exceed every thing that has been found strange in bodily variety among the human race. Swine with solid hoofs were known to the ancients, and large herds of them are found in Hungary, Sweden, &c. In the like manner, the European swine, first carried by the Spaniards, in 1509, to the island of Cuba, at that time celebrated for its pearl fishery, degenerated into a monstrous race, with hoofs which were half a span in length."

From these facts, our author concludes, that it is absurd to allow the vast variety of swine to have descended from one original pair, and to contend that the varieties of men are so many distinct species.

MANDING, a large state in the interior of Africa, of which the only satisfactory account that we have is by Mr Park, who, for several months, was hospitably entertained in Kamalia, one of its towns, situated in 12° 40′ N. Lat. and 6° 40′ W. Long. The government of Manding appeared to our author to be a sort of republic, or rather an oligarchy. Every town is indeed governed by a chief magistrate called Mansa, which usually signifies king; but the chief power of the state, in the last resort, is lodged in the assembly of these mansas (A). The case, however, is different in other countries, which are occupied by people who have emigrated from Manding; for in all the Mandingo states near

(A) Mr Park, for the most part, writes with remarkable perspicuity; but we are not sure that here we have not mistaken his meaning. He says, that the chief power of the state is lodged in the assembly of that *whole body*; but we think, that by the whole body must be meant the body of *Mansas*, otherwise the government could not be called an oligarchy.

near the Gambia, the government is monarchical, tho' the power of the sovereign is by no means unlimited.

As Mr Park's route was confined to a tract of country, bounded nearly by the 12th and 15th parallels of latitude, the climate throughout the whole was nearly the same as that of Manding, and extremely hot: Yet, where the country ascended into hills, he found it comparatively cool and pleasant; though none of the districts which he traversed could be called mountainous. About the middle of June, the hot and sultry atmosphere is agitated by violent gusts of wind (called *tornadoes*), accompanied with thunder and rain. These usher in what is denominated *the rainy season*; which continues until the month of November. During this time, the diurnal rains are very heavy; and the prevailing winds are from the south-west. The termination of the rainy season is likewise attended with violent tornadoes; after which the wind shifts to the north east, and continues to blow from that quarter during the rest of the year.

When the wind sets in from the north-east, it produces a wonderful change in the face of the country. The grass soon becomes dry and withered; the rivers subside very rapidly, and many of the trees shed their leaves. About this period is commonly felt the *harmattan*, a dry and parching wind, blowing from the north east, and accompanied by a thick smoky haze; through which the sun appears of a dull red colour. This wind, in passing over the great desert of Sahara, acquires a very strong attraction for humidity, and parches up every thing exposed to its current. It is, however, reckoned very salutary, particularly to Europeans, who generally recover their health during its continuance. The truth of this our author experienced both at Kamalia and Pisania, when he had been brought to the very brink of the grave by sickness.

Whenever the grass is sufficiently dry, the negroes set it on fire; but in Ludamar, and other Moorish countries, this practice is not allowed; for it is upon the withered stubble that the Moors feed their cattle until the return of the rains. The burning of the grass in Manding exhibits a scene of terrific grandeur. "In the middle of the night (says Mr Park), I could see the plains and mountains, as far as my eye could reach, variegated with lines of fire; and the light reflected on the sky, made the heavens appear in a blaze. In the day time, pillars of smoke were seen in every direction; while the birds of prey were observed hovering round the conflagration, and pouncing down upon the snakes, lizards, and other reptiles, which attempted to escape from the flames." This annual burning is soon followed by a fresh and sweet verdure, and the country is thereby rendered more healthful and pleasant.

Though many species of the edible roots, which grow in the West India islands, are found in Africa, yet our traveller never saw, in any part of his journey, either the sugar cane, the coffee, or the cocoa tree; nor could he learn, on inquiry, that they were known to the natives. The pine-apple, and the thousand other delicious fruits which the industry of civilized man (improving the bounties of nature), has brought to so great perfection in the tropical climates of America, are here equally unknown. He observed, indeed, a few orange and banana trees, near the mouth of the Gambia; but whether they were indigenous, or were formerly planted there by some of the white traders, he could not positively learn.

Concerning property in the soil, it appeared to Mr Park, that the lands in native woods were considered as belonging to the king, or (where the government was not monarchical) to the state. When any individual of free condition had the means of cultivating more land than he actually possessed, he applied to the chief man of the district, who allowed him an extension of territory, on condition of forfeiture if the lands were not brought into cultivation by a given period. The condition being fulfilled, the soil became vested in the possessor; and, for aught that appeared, descended to his heirs.

The Mandingoes are a very gentle race of people; cheerful in their dispositions, inquisitive, credulous, simple, and fond of flattery. The men are commonly above the middle size, well shaped, strong, and capable of enduring great labour; the women are good natured, sprightly, and agreeable. The dress of both sexes is composed of cotton cloth of their own manufacture; that of the men is a loose frock, not unlike a surplice, with drawers which reach half way down the leg; and they wear sandals on their feet, and white cotton caps on their heads. The womens dress consists of two pieces of cloth, each of which is about six feet long and three broad; one of these they wrap round the waist, which, hanging down to the ancles, answers the purpose of a petticoat; the other is thrown negligently over the bosom and shoulders. Both men and women among the Mandingoes seem to have an invincible propensity to commit depredations on the property of unprotected strangers; whilst such is the good nature of those poor heathens, that they will readily sympathise in the sufferings, relieve the distresses, and contribute to the personal safety, of the very strangers whom they are bent upon plundering.

Among the Mandingoes, the parental and filial affection is remarkably strong between the mother and her child; but not so between the father and his children. This, as Mr Park observes, is easily accounted for. The system of polygamy, while it weakens the father's attachment, by dividing it among the children of different wives, concentrates all the mother's jealous tenderness to one point, the protection of her own offspring. He perceived, with great satisfaction too, that the maternal solicitude extended, not only to the growth and security of the person, but also, in a certain degree, to the improvement of the mind of the infant; for one of the first lessons in which the Mandingo women instruct their children, is *the practice of truth*.

The Mandingo women suckle their children until they are able to walk of themselves. Three years nursing is not uncommon; and during this period, the husband devotes his whole attention to his other wives. To this practice it is owing, that the family of each wife is seldom very numerous. Few women have more than five or six children. As soon as an infant is able to walk, it is permitted to run about with great freedom. The mother is not over solicitous to preserve it from slight falls, and other trifling accidents. A little practice soon enables a child to take care of itself, and experience acts the part of a nurse. As they advance in life, the girls are taught to spin cotton, and to beat corn, and are instructed in other domestic duties; and the

Mandingoes.

the boys are employed in the labours of the field. Both ſexes, whether Buſhreens or Kafirs, on attaining the age of puberty, are circumciſed. This painful operation is not conſidered by the Kafirs ſo much in the light of a religious ceremony, as a matter of convenience and utility. They have, indeed, a ſuperſtitious notion, that it contributes to render the marriage ſtate prolific.

When a young man takes a fancy to a young girl, and wiſhes to marry her, it is by no means conſidered as neceſſary that he ſhould make an overture to the girl herſelf. The firſt object is to agree with the parents, concerning the recompence to be given them for the loſs of the company and ſervices of their daughter. The value of two ſlaves is a common price, unleſs the girl is thought very handſome; in which caſe, the parents will raiſe their demand very conſiderably. If the lover is rich enough, and willing to give the ſum demanded, he then communicates his wiſhes to the damſel: but her conſent is by no means neceſſary to the match; for if the parents agree to it, and eat a few *kolla nuts*, which are preſented by the ſuitor as an earneſt of the bargain, the young lady muſt either have the man of their choice, or continue unmarried, for ſhe cannot afterwards be given to another. If the parents ſhould attempt it, the lover is then authoriſed, by the laws of the country, to ſeize upon the girl as his ſlave. At the celebration of a marriage, no religious ceremony ſeems to be practiſed. A ſelect number of people are indeed invited to the wedding, and feaſted; but conſummation conſtitutes the marriage; for towards the morning, the new married couple are always diſturbed by the women, who aſſemble to inſpect the nuptial ſheet (according to the manners of the ancient Hebrews, as recorded in Scripture), and dance round it. This ceremony is thought indiſpenſably neceſſary; nor is the marriage conſidered as valid without it.

The Mandingoes, and indeed all the negro ſtates, whether Mahomedan or Pagan, allow a plurality of wives. The conſequence is, that the wives frequently quarrel among themſelves. When this happens, the huſband decides between them; and ſometimes finds it neceſſary to adminiſter a little corporal chaſtiſement before tranquillity can be reſtored. But if any one of the ladies complains to the chief of the town, that her huſband has unjuſtly puniſhed her, and ſhewn an undue partiality to ſome other of his wives, the affair is brought to a public trial. In theſe *palavers*, however, which are conducted chiefly by married men, our author was informed, that the complaint of the wife is not always conſidered in a very ſerious light; and the complainant herſelf is ſometimes convicted of ſtrife and contention, and left without remedy. If ſhe murmurs at the deciſion of the court, the magic rod of *Mumbo Jumbo* ſoon puts an end to the buſineſs. See Mumbo Jumbo in this *Suppl*.

A child, among them, is named when it is ſeven or eight days old. The ceremony commences by ſhaving the infant's head; and a diſh called *degu*, made of pounded corn and ſour milk, is prepared for the gueſts. If the parents are rich, a ſheep or a goat is commonly added. This feaſt is called *ding koon lee*, "the child's head ſhaving." During Mr Park's ſtay at Kamalia, he was preſent at four different feaſts of this kind, and the ceremony was the ſame in each, whether the child belonged to a Buſhreen or a Kafir. The ſchoolmaſter, who officiated as prieſt on thoſe occaſions, and who is neceſſarily a Buſhreen, firſt ſaid a long prayer over the *dega*; during which, every perſon preſent took hold of the brim of the calabaſh with his right hand. After this, the ſchoolmaſter took the child in his arms, and ſaid a ſecond prayer; in which he repeatedly ſolicited the bleſſing of God upon the child, and upon all the company. When this prayer was ended, he whiſpered a few ſentences in the child's ear, and ſpat three times in its face; after which he pronounced its name aloud, and returned the infant to the mother. This part of the ceremony being ended, the father of the child divided the *dega* into a number of balls, one of which he diſtributed to every perſon preſent. And inquiry was then made, if any perſon in the town was dangerouſly ſick, it being uſual, in ſuch caſes, to ſend the party a large portion of the *dega*, which is thought to poſſeſs great medical virtues.

The Mandingoes have no artificial method of dividing time. They calculate the years by the number of *rainy ſeaſons*. They portion the year into *moons*, and reckon the days by ſo many *ſuns*. The day they divide into morning, mid day, and evening; and further ſubdivide it, when neceſſary, by pointing to the ſun's place in the heavens. Our author frequently inquired of ſome of them, what became of the ſun during the night, and whether we ſhould ſee the ſame ſun, or a different one, in the morning? But that ſubject appeared to them as placed beyond the reach of human inveſtigation; they had never indulged a conjecture, nor formed any hypotheſis, about the matter. The moon, by varying her form, has more attracted their attention. On the firſt appearance of the new moon, which they look upon to be newly created, the Pagan natives, as well as Mahomedans, ſay a ſhort prayer; and this ſeems to be the only viſible adoration which the Kafirs offer up to the Supreme Being. This prayer is pronounced in a whiſper; the party holding up his hands before his face: its purport is to return thanks to God for his kindneſs through the exiſtence of the paſt moon, and to ſolicit a continuation of his favour during that of the new one. At the concluſion, they ſpit upon their hands, and rub them over their faces. Great attention is paid to the changes of this luminary in its monthly courſe; and it is thought very unlucky to begin a journey, or any other work of conſequence, in the laſt quarter. An eclipſe, whether of the ſun or moon, is ſuppoſed to be effected by witchcraft. The ſtars are very little regarded; and the whole ſtudy of aſtronomy appears to them as a uſeleſs purſuit, and attended to by ſuch perſons only as deal in magic.

Their notions of geography are equally puerile. They imagine that the world is an extended plain, the termination of which no eye has diſcovered; it being, they ſay, overhung with clouds and darkneſs. They deſcribe the ſea as a large river of ſalt water, on the farther ſhore of which is ſituated a country called *Tobaubo doo*: "the land of the white people." At a diſtance from Tobaubo doo, they deſcribe another country, which they allege is inhabited by cannibals of gigantic ſize, called *Kcomi*.

Mr Park ſays he has converſed with all ranks and conditions of negroes on the ſubject of their faith, and that he can pronounce, without the ſmalleſt ſhadow of doubt, that the belief of one God, and of a future ſtate of reward and puniſhment, is entire and univerſal among them.

Manding. them. It is remarkable, however, that, except on the appearance of a new moon, as before related, the Pagan natives do not think it neceſſary to offer up prayers and ſupplications to the Almighty. They repreſent the Deity, indeed, as the creator and preſerver of all things; but in general they conſider him as a Being ſo remote, and of ſo exalted a nature, that it is idle to imagine the feeble ſupplications of wretched mortals can reverſe the decrees, and change the purpoſes, of unerring wiſdom. The concerns of this world, they believe, are committed by the Almighty to the ſuperintendance and direction of ſubordinate ſpirits, over whom they ſuppoſe that certain magical ceremonies have great influence. A white fowl, ſuſpended to the branch of a particular tree, a ſnake's head, or a few handfuls of fruit, are offerings which ignorance and ſuperſtition frequently preſent, to deprecate the wrath, or to conciliate the favour, of theſe tutelary agents.

The Mandingoes ſeldom attain extreme old age. At forty, moſt of them become grey haired, and covered with wrinkles; and but few of them ſurvive the age of fifty-five, or ſixty. Yet their diſeaſes appeared but few; fevers and fluxes being the moſt common, and the moſt fatal. For theſe they generally apply *ſaphies*, i. e. charms, to different parts of the body; though ſometimes, on the firſt attack of a fever, the patient is, with great ſucceſs, placed in a ſort of vapour bath. The other diſeaſes which prevail among the negroes, are the *yaws*, the *elephantiaſis*, and a *leproſy* of the very worſt kind, together with the *Guinea worm*, which they attribute to bad water.

When a perſon of conſequence dies, the relations and neighbours meet together, and manifeſt their ſorrow by loud and diſmal howlings. A bullock or goat is killed for ſuch perſons as come to aſſiſt at the funeral; which generally takes place in the evening of the ſame day on which the party died. The negroes have no appropriate burial places, and frequently dig the grave in the floor of the deceaſed's hut, or in the ſhade of a favourite tree. The body is dreſſed in white cotton, and wrapped up in a mat. It is carried to the grave, in the duſk of the evening, by the relations. If the grave is without the walls of the town, a number of prickly buſhes are laid upon it, to prevent the wolves from digging up the body; but our author never obſerved that any ſtone was placed over the grave as a monument or memorial.

With reſpect to employment, the men cultivate the ground, or catch fiſh in large rivers; while the women manufacture cotton cloth. It is only the ſpinning and the dyeing, however, that are performed by the women; for the web, which is ſeldom more than four inches broad, is wove by the men in a loom made exactly upon the ſame principle as that of Europe. As the arts of weaving, dyeing, ſewing, &c. may eaſily be acquired, thoſe who exerciſe them are not conſidered in Africa as following any particular profeſſion; for almoſt every ſlave can weave, and every boy can ſew. The only artiſts which are diſtinctly acknowledged as ſuch by the negroes, and who value themſelves on exerciſing appropriate and peculiar trades, are the manufacturers of leather and of iron. The firſt of theſe are called *Karrankea* (or as the word is ſometimes pronounced *Gaungay*). They are to be found in almoſt every town, and they frequently travel through the country in the exerciſe of their calling. They tan and dreſs leather with very great expedition, by ſteeping the hide firſt in a mixture of wood-aſhes and water, until it parts with the hair; and afterwards by uſing the pounded leaves of a tree, called *goo*, as an aſtringent.

The manufacturers in iron are not ſo numerous as the *Karrankeas*; but they appear to have ſtudied their buſineſs with equal diligence. The negroes on the coaſt being cheaply ſupplied with iron from the European traders, never attempt the manufacturing of this article themſelves; but in the inland parts, the natives ſmelt this uſeful metal in ſuch quantities, as not only to ſupply themſelves from it with all neceſſary weapons and inſtruments, but even to make it an article of commerce with ſome of the neighbouring ſtates. During our author's ſtay at Kamalia, there was a ſmelting furnace at a ſhort diſtance from the hut where he lodged, and the owner and his workmen made no ſecret about the manner of conducting the operation; and readily allowed him to examine the furnace, and aſſiſt them in breaking the iron-ſtone. The proceſs it is needleſs to deſcribe; though it be proper to obſerve, that the maſs of metal obtained by it was rather ſteel than iron. Moſt of the African blackſmiths are acquainted alſo with the method of ſmelting gold, in which proceſs they uſe an alkaline ſalt, obtained from a ley of burnt corn-ſtalks evaporated to dryneſs. They likewiſe draw the gold into wire, and form it into a variety of ornaments, ſome of which are executed with a great deal of taſte and ingenuity.

The reader will obſerve, that in the extracts which we have made from Mr Park's intereſting travels, the terms African and Negro are frequently uſed as if all Africans and Negroes were Mandingoes. The reaſon is, that the Mandingoes were not only the moſt numerous tribe which he viſited, but were alſo ſpread over all that tract of country which he traverſed.

MANIANA, a ſmall negro kingdom lying between 12° and 14° North Lat. and between the meridian of Greenwich and 1° and 30′ Weſt Long. Its inhabitants, as Mr Park was informed by a variety of people in many different kingdoms, are remarkable for cruelty and ferocity; carrying their reſentment to their enemies ſo far as never to give quarter, and even indulging themſelves with banquets of human fleſh. Hence the inhabitants of Bambarra, who carried on with them a long and bloody war, and muſt of courſe be well aſcertained of the fact, call them *Ma dummulo*, which ſignifies meneaters.

MANURE is ſo eſſential to agriculture, that the want of it, or an improper manner of uſing it, is the principal cauſe of the ſterility of a country. We have therefore treated of manures and their action at ſome length in the article AGRICULTURE in the *Encyclopædia*; but as the theoretical part of that diſquiſition reſts in a great meaſure on the doctrine of phlogiſton, which is now exploded, it may not be improper to reſume the ſubject here. Experience, however being, after all, the only guide which the farmer can ſafely and confidently follow, inſtead of amuſing our readers with theories of our own, we ſhall lay before them the obſervations of a man who ſeems to have united theory with practice.

"The uſe of manures (ſays M. Parmentier *) has been known in all ages, but we are yet far from having any clear and preciſe ideas of the nature of the juices which

Manure.

which are destined for the nourishment of vegetables, and of the manner in which they are transmitted to their organs. The writers on agriculture, who have endeavoured to explain these matters, perceiving salts in most plants, were persuaded that these salts, by the help of water and heat, passed, in a saline form, through the vegetable filter. These first philosophers did not hesitate to consider every thing that has been done by the industry of man, to improve the nature of land, and its productions, as merely forming reservoirs of these salts, which they considered as the principle of fertility. This opinion was so well established among the improvers of land, that, to this day, many of them have no object in view, in their operations, but to disengage salts; and, when they attempt to explain certain phenomena which take place in their fields or orchards, they talk confidently about the *nitre of the air, of rain, of snow, of dew, and fogs;* of the *salts of the earth, of dung, of marle, of lime, of chalk,* &c. and make use of those vague terms, *oil, sulphur, spirit,* &c. which ought henceforward to be banished from our elementary books on agriculture.

"Among the authors who have attacked, and combated with most success, the opinion that the fruitfulness of soils, and the aliment of vegetables, reside in saline substances, must be reckoned Eller and Wallerius. These philosophers examined, by every means which chymistry at that time could furnish, the various kinds of earth proper for cultivation, and also those substances which have always been considered as the most powerful manures, without being able to obtain, from any of them, any thing more than mere atoms of salt.

"Animated with the same zeal, and taking advantage of the instructions found in their writings, I thought it necessary to determine, by experience, whether, as has been asserted, there really exist neutral salts in earths; and also, whether those earths are more fertile in proportion to the quantity of such salts they contain. With this view, I lixiviated, by means of distilled water, many species of cultivated earths, taken in various states, from fresh earth to that which had been impoverished by the growth of several crops; I also tried dung, reduced more or less into the state of mould; and likewise the most active manures, such as the offal of animal substances rotted by putrefaction; but in none of these, however carefully analyzed, were found any salts in a free state. They contain indeed the materials proper for forming salts, but if they contain any ready formed, it is merely by accident.

"The researches of Kraft, and those of Althof, were not attended with different results. Having sown some oats in ashes, not lixiviated, and in sand strongly impregnated with potash and with saltpetre, and having found that the oats did not grow, they concluded that neutral salts, and alkalies, not only retarded the growth of vegetables, but that they absolutely prevented it. It is well known that in Egypt there are districts where the earth is entirely covered with sea-salt, and these districts are quite barren. It is probably owing to this property of sea-salt, that the Romans were accustomed to scatter large quantities of it over fields where any great crime had been committed, and of which they wished to perpetuate the remembrance, by rendering the part barren for a certain time.

"The idea that salts had great influence in vegetation, ought to have been greatly weakened by the following simple reflection. Supposing that salts existed in garden mould, they would be very soon dissolved by the rain, and carried away, towards the lower strata of the earth, to a depth to which the longest roots would not reach. Indeed the famous experiment of Vanhelmont would have been sufficient to have destroyed the above opinion, if it did not generally happen that we are no sooner set free from one error than we fall into another not less extraordinary. The surprising effects of vegetation brought about by the overflowing of water, and in the neighbourhood of salt marshes, and the infinite number of inhaling capillary tubes observed upon the surface of vegetables, led to an opinion that the air and water, absorbed by the roots and leaves of plants, were only vehicles loaded with saline matter, analogous to the vegetables nourished by them.

"To the experiment of Vanhelmont, which was repeated by many accurate observers, succeeded those of modern philosophers; from which it clearly appeared, that plants could grow, and produce fruit, in the air of the atmosphere, and in distilled water, also in pure sand, in powdered glass, in wet moss or sponge, in the cavity of fleshy roots, &c. and that plants which had nothing but the above-mentioned fluids for their nourishment, gave, when submitted to chymical analysis, the same products as those which had undergone their process of vegetation in a soil perfectly well manured. It was also observed, that the most barren soils were rendered fertile when they were properly supplied with water by canals; and the efficacy of irrigation was repeatedly evinced in different ways: from these observations was formed the following system, that water rises in plants in the form of vapour, as in distillation; that air introduces itself into their pores; and that, if salts contribute to the fruitfulness of soils, it is only in consequence of their containing the two fluids above mentioned in great abundance."

Our author, after making many experiments upon various soils and salts, and after attending minutely to the process of vegetation, thinks himself warranted to maintain, "that saline substances have no sensible effects in promoting vegetation, except inasmuch as they are of a deliquescent nature, have an earthy basis easily decomposed, and are used only in small quantity. In those circumstances they have the power of attracting, from the immense reservoir of the atmosphere, the vapours which circulate in it; these vapours they retain, along with the moisture that is produced from rain, snow, dew, fog, &c. which moisture they prevent from running together in a mass, or from being lost, either by exhaling into the air of the atmosphere, or by filtering itself through the inferior strata of the earth, and thereby leaving the roots of vegetables dry; they distribute that moisture uniformly, and transmit it, in a state of great division, to the orifices of the tubes destined to carry it into the texture of the plant, where it is afterwards to undergo the laws of assimilation. As every kind of vegetable manure possesses a viscous kind of moisture, it thereby partakes of the property of deliquescent salts. In short, the preparation of land for vegetation has no other object in view but to divide the earthy particles, to soften them, and to give them a form capable of producing the above mentioned effects. It is sufficient, therefore, that water, by its mixture with

Manure. with the earth and the manure, be divided, and spread out so as to be applied only by its surface, and that it keep the root of the plant always wet, without drowning it, in order to become the essential principle of vegetation. But as plants which grow in the shade, even in the best soil, are weakly, and as the greater part of those which are made to grow in a place that is perfectly dark neither give fruit nor flowers, it cannot be denied that the influence of the sun is of great importance in vegetable economy."

Such was the opinion which our author gave of the manner in which salts act in vegetation, at a time when it was not known that air and water (which had been so long considered as elements), far from being simple substances, are capable of being decomposed by a great variety of operations both of nature and art; and nothing was wanting to complete his theory, but to know that air and water act their part in vegetation only in a state of decomposition; and that if earth well manured is a better matrix than water itself, it is because such earth has the power of converting the water into gases which are easily absorbed, and which, while their absorption takes place, communicate to the plants a motion and heat which they received when taking the form of gas, and which they lose when they enter again into combination; whence it is natural to conclude, that this motion and this heat must necessarily develope themselves in seeds, and maintain the vital action in plants.

What is a vegetable, considered chemically, according to the present state of our knowledge? It is, say the chemists, a compound of hydrogen, oxygen, and carbon, the proportions of which vary according to the agents which have concurred to its developement, and according to the matrix which received and assimilated them, in order to create those combinations which are varied to infinity, by their forms and properties, and known by the generic terms of salt, oil, and mucilage. It appears, therefore, needless to seek these combinations in the different substances which are used for manure, when we wish to determine the nature of them, and explain their manner of acting in vegetation; because, supposing it true that these salts, these oils, or these mucilages, exist in their combined state, nothing but their constituent elements, namely, hydrogen, oxygen, and carbon, can possibly have any action.

The superiority of animal substances, as manures, and the remarkable luxuriance of those plants which are watered with putrid water, prove incontestibly, that the putrid state is favourable to vegetation, and that every substance which is liable to enter, to a certain degree, into that state, contributes very powerfully thereto. The most aerated waters are, in this case, the most beneficial. It is observed that rain, particularly in stormy weather, quickens vegetation so much, that the gardeners in the neighbourhood of Paris are often obiged to drench their plants with water taken from their wells, which, in consequence of its rawness, or its want of air, retards the vegetation of the plants; either because it precipitates the meteorised or electrified water, or because, by being mixed with the other water, it diminishes its fertilizing quality; whereas, in summer, this same well water, by being exposed to the sun for some days, acquires a smell like that of stale eggs, loses its rawness, and becomes very fit for accelerating vegetation. An atom of vegetable or animal matter is, at that time, sufficient to bring about more quickly this state of putrefaction; while these same substances, by being employed in certain proportions, far from acting as a leaven on the liquids which hold them in solution, preserve those liquids, or at least make them more slow to change.

Salts and dung, therefore, are not merely decomposed by the power of vegetation; by furnishing the results of their decomposition, they also act in the manner of leavens, the action of which is scarcely perceptible in cold or dry weather; but when they are heated by the sun, and sufficiently penetrated with moisture, they very soon enter into a sort of fermentation, suffering the various gases with which they are provided to escape. Thus manures may be considered as decomposing instruments, provided by nature, and prepared by art, to act upon water so as to bring it to a proper state of attenuation. The substances which enter into the composition of plants are, therefore, nothing but products of the decomposition of air and water, and combinations of the constituent principles of these two fluids, determined by the power which presides in the seed, and which thence has passed into the plant.

It is now easy to account for the effects of charcoal-powder, straw, &c which are made use of to cover ground during long droughts with undoubted benefit: they are mechanical means of preventing the dissipation of moisture, and of determining it to take the form of those gaseous fluids which have such powerful effect in vegetation. As water is composed of hydrogen and oxygen, it is not surprising that, when assisted by the influence of the sun, and that of electricity, it is capable of forming, almost by itself, the solids and fluids of vegetables; taking from the atmosphere the carbon it stands in need of, to give them their most essential characters. We say their most essential characters; for those terrestrial plants which have grown in air and water do not abound in principles, and their offspring, when they have any, is by no means vigorous. We see also, that plants which are naturally of an aquatic nature, have in general but little smell, because the medium in which they live and grow furnishes only a small quantity of carbon, in proportion to the hydrogen and oxygen, which are the constituent principles of water. This is the reason why, in cold and wet years, flowers are less odoriferous, fruit less full of flavour, and more difficult to be preserved. The germ of their reproduction is weak; and they are, if the expression may be used, in a sort of dropsy; that is to say, they are loaded with the principles which constitute water, and even with water itself.

These observations, to which more might be added, may serve to explain why vegetation is slow and weak in a soil which is too much charged with saline matter, while it is rendered quick and vigorous by a small quantity of this same matter; and why earth, which is perfectly lixiviated, and watered, from time to time, with distilled water only, is capable of giving to bitter plants their bitterness, to sweet ones their sweetness, to acid ones their acidity, to aromatic ones their spiciness, and to poisonous ones their deleterious qualities; in short, why the inherent characters of plants are more strongly marked, in proportion as the soil in which they grow is furnished with natural or mechanical means to produce

Manure.

duce a quantity of gas necessary to the formation of the substances on which those characters depend.

If a nitrous or marine plant can, even when growing in a soil destitute of nitre or sea salt, occasion the production of these salts, it must be allowed that such plants would vegetate more strongly, and contain more of such salts, if they grew in soils more abounding in materials proper to form them. Thus, the different species of samphire, glasswort, sea wrack, &c. flourish on the borders of the sea, such soils being strongly impregnated with the fluids necessary to form the muriatic gas and sea salt which enter into the composition of those plants; while the sun flower, pellitory, &c. succeed best in earth which is mixed with the ruins of old buildings, in which the materials for the production of nitrous gas, and even of nitre itself, are very abundant. In short, the organization of these plants is a real elaboratory for forming the forementioned salts.

Those plants which, for their vegetation, require the most assistance from the soil and manure, are very apt to contract a disagreeable taste, if either the soil or manure are capable of supplying the principles from which it is acquired. The class *tetradynamia*, particularly all sorts of cabbages (which contain sulphur ready formed), contract a bad taste in a soil composed of mud and dung, because these substances, as they are decomposed, furnish a great quantity of hepatic gas, or of sulphurised hydrogen gas; yet plants of another class may grow in the same soil, close by the cabbages, without partaking even in the smallest degree of the bad taste of the latter. The plants last mentioned, when growing in hepatic gas, retain only so much of it as is sufficient for the production of the substances of which they are formed; the overplus, which could not be assimilated, is thrown out by the excretory vessels, after undergoing those modifications which the digestive juices and organization of the plant, and the state of the atmosphere, have produced.

Thus we see that those plants which abound most in oily, saline, and mucilaginous principles, are generally such as require a soil well manured. Tobacco, for instance, gives forty pounds of alkaline salt or potash from every hundred weight of ashes: this plant may, by being buried in the ground, be converted into a very powerful manure; while other plants, which thrive in a middling soil, and appear as vigorous, are, in general, such as have not so great a quantity of principles in their composition, and when thrown on the dunghill, and left to rot, furnish very little manure. From such observations, it may perhaps not be impossible hereafter to judge, by the analysis of a plant, not only whether it requires a large or a small quantity of manure, but likewise what kinds of soil and manure are most fit to promote its vegetation: wild plants also may serve to shew the nature of the soil which they seem most to flourish in.

Besides the physical action of manures, they have a very evident mechanical action. When mixed with earth, in a certain proportion, they not only render it more permeable to water, but the roots of plants can, with greater ease, acquire their proper size and form in it: in other cases, manures tend to unite that earth which is too loose, and, by rendering it more tenacious, they prevent the water from being lost, and the roots from becoming dry. Those manures which are called *warm* are suited to cold lands, not only because they render them less compact, but also because they take off a part of that moisture which such lands always have in too great quantity. Cold manures, on the other hand, by their viscid quality, give tenacity to dry and hot soils, attracting and retaining, for a longer time, the moisture which comes in their way. The nature of the soil must therefore determine what kind of manure it stands in need of, and also whether cultivating it by means of oxen or by horses is preferable; for the manures produced from these two animals have those opposite qualities which we have above described. By such observations, we shall perhaps be able to resolve a question, respecting which the sentiments of cultivators in many parts of the kingdom are much divided.

It cannot, however, be denied, that the earth is able of itself to serve as a basis and support to plants, and that it has an action more or less evident upon air, upon water, and upon dung. There is a well-known method of distinguishing clay from other earths: by merely breathing upon it, a smell is immediately perceived, sufficiently strong to shew that a decomposition and fresh combination have taken place. In summer, after a drought of some days continuance, there always arises in the fields a particular smell during a shower of rain; and there is no kind of vegetable manure which, when mixed with earth, does not send forth a smell. This proves, that the nature of the soil must have an influence, not only upon air and upon water, but also upon the effect of manures; and that before we speak of their power, we should always specify what kind of earth they were applied to; because when manures and earth are mixed together, there ensues an action and reaction more or less favourable to vegetation.

Having examined to what degree air and water enter, in substance, into the vessels of plants, and having shewn that the principal action of earth, of salts, and of manures, consists in preparing, elaborating, and decomposing these two fluids, and in giving to the products of their decomposition the forms they require, to accomplish the purpose of nature in vegetation, our author makes some observations upon the particular effects of certain substances used for improving land, such as marl, lime, chalk, and wood ashes; which are usually applied either to an exhausted soil, in order to restore it, or to a drooping plant, with a view to give it strength. Of the efficacy of these substances no one doubts, but it does not appear that we are equally agreed respecting their manner of acting.

Marl (a manure whose effects are well known, and which is found to be of the greatest benefit in those districts where it can be procured in sufficient quantity) is capable of acting in the same manner as the most fertile soil, when the principles of which it is composed, namely, clay, sand, calcareous earth, and magnesian earth, are justly proportioned to each other. But it is sometimes compact and tenacious, because it contains a superabundant portion of clay, and at other times porous and friable, because it contains too much sand, and therefore is not in general fit for vegetation by itself. These considerations ought always to be our guide when we mean to employ marl as a manure.

It has been supposed that *to marl* was a sort of technical expression, intended to denote the bringing together

ther

Manure. ther or dividing the earthy particles by means of clay or sand. It appears to our author, that neither of the above operations can properly be called *marling*; because in either case, all we do is, to put the soil into a situation to receive and to profit by the influence of the atmosphere, and that of the manures made use of. The peculiar principle of marl is, that part of it which, like lime, acts very powerfully upon the different aeriform fluids, is easily reduced to powder, effervesces with acids, and sends forth a quantity of air bubbles when water is poured upon it. Now this matter, which in a particular manner does the office of manure, resides neither in clay nor in sand. Upon the proportion of it depends the duration of the fertility it produces; consequently it is of importance, when we make use of marl, to know which of its constituent parts it contains in the greatest proportion, otherwise in some cases we should only add one common kind of earth to another. Hence our author infers, that for a chalky soil clay is the proper manure, and that in such a soil a clay bottom is of more value than a gold mine.

"Wood-ashes, as a manure, may be, in some respects, compared to marl; at least they contain the same earths as those which generally enter into the composition of marl, but they contain a greater quantity of saline substances, proceeding from the vegetables of which they are the residue, and from the process made use of in their combustion; a process which increases their activity, and should render us careful in what manner and for what purposes we employ them. Wood ashes, when scattered over fields, at proper times and in proper quantities, destroy weeds, and encourage the vegetation of good plants. But do the ashes produce this effect by a sort of corrosive power? I cannot (says our author) think it; for in that case all kinds of plants would indiscriminately be acted upon by them, and to a certain degree destroyed.

"Besides, the ashes of fresh wood are seldom employed until they have been lixiviated, in which state they are deprived of their caustic principle; those ashes which are most commonly made use of for manure are produced either from wood that has been floated in water, or from turf, or from pit-coal, and contain little or no alkaline salt.

"It appears much more probable that ashes, when laid upon ground, destroy the weeds by a well known effect, namely, by seizing with eagerness that moisture which served to produce those weeds, and which in a superabundant quantity is necessary to their existence and support. Whereas those plants which have a firmer texture and a longer root, which are rendered strong by age and by having withstood the rigour of winter, and which are in fact the plants of which the fields are composed, do not suffer any damage from the application of the ashes; but, on the contrary, by being freed from the superfluous weeds which stifled them, and robbed them of a part of their sustenance, they receive a quantity of nourishment proportioned to their wants. The state of relaxation and languor to which they were reduced by a superabundance of water, leaves them, the soil gets its proper consistence, and the grass, corn, &c. acquiring the strength and vigour which is natural to them, soon overcome the moss, rushes, and other weeds; thus a good crop, of whatever the field consists of, is produced. It is in the above manner that wood ashes act, whenever in the spring it is necessary to apply them to meadows, corn fields, &c. the plants of which are stifled and weakened by a luxuriant vegetation of weeds, the usual consequence of mild and wet winters.

"When wood ashes produce an effect different from what is above described, it is either because they happen to contain too much alkaline salt, or that they are laid on the ground in too great quantity, or that the fields to which they are applied were not sufficiently wet to restrain their action; for when they are scattered upon cold soils, and buried by the plough before the time of sowing, they are, like lime, of great service. The last-mentioned substance is very efficacious in other circumstances; and there is a well-known method of using it, practised by the Germans, as follows: A heap of lime is formed by the side of a heap of poor earth, and water is poured upon the lime; the earth is then thrown over it, and becomes impregnated with the vapours which escape from the lime while it is slaked. The earth, after being thus aerated, may be separated; and although no lime remains mixed with it, is, by the operation just described, rendered capable of giving a luxuriant vegetation to whatever plants may be put into it.

"It is possible, therefore, to aerate earth as well as fluids; for this purpose, by mixing it with certain substances, during their decomposition, we must attach to it the principles of which those substances are composed; from which there results a matter so loaded with gas, as to form a more compound substance, and one which has acquired new properties. The Arabians, for example, who take great pains to improve their land, are accustomed to make large pits, which they fill with animals which happen to die: these pits they afterwards cover with calcareous or clayey earth; and after some time these earths, which of themselves are sterile, acquire the properties of the richest manures.

"The foregoing observations may at least be considered as proving, that those substances which, when employed fresh and in too great quantity, are most prejudicial to vegetation, have, on the contrary, an advantageous effect, when they are previously made to undergo a fermentation; or when they are mixed with earth or water, in a proportion adapted to the end proposed. The grass of fields in which cattle or poultry go to feed, after the first or second crop of hay, appears to be dried by the urine and dung of those animals; as if fire had been applied to it; whereas these same excrementitious substances, when combined with earth, or diluted with water, are capable, without any other preparation, of performing the office of good manure.

"But if animal secretions, when applied in substance to plants, were capable of acting upon them, as is affirmed, in such a way as to corrode or burn them, how could seed which has been swallowed, and escaped the action of the digestive powers, be prolific when thrown out by the animal, after having remained so long in its dung? yet we often see oats, so circumstanced, grow and produce seed. Is it not more consistent with experience and observation to suppose, that these excrementitious substances, being still endowed with animal heat, and with an organic motion, diffuse round plants in vegetation a deleterious principle or inflammable gas, which destroys them; for soon after their application, the foliage of the plant grows yellow, dries up, and the plant withers, unless there happens a shower of rain

which

Manure.

which revives it. When theſe ſubſtances are diluted, by being mixed with water and earth, they loſe that principle which is ſo deſtructive to vegetable life, and an incipient fermentation augments their power as a manure, ſo that they may be immediately made uſe of without any apprehenſion of injury from their effects.

mit a greater fault, than to put more than a certain quantity of them into the water he means to make uſe of to water his young plants; in ſhort, this kind of manure is to be uſed in a very ſparing manner; and he that is too prodigal of it will find, to his coſt, that exceſs, even of that which is otherwiſe beneficial, becomes an evil.

"It muſt certainly be allowed, that excrementitious ſubſtances are a very advantageous manure for cold ſoils, and ſuited to moſt vegetable productions; a long experience of their effects over a large tract of country, and the acknowledged intelligence of the Flemiſh farmers, ought to be conſidered as ſufficient to overcome the prejudice that has been raiſed againſt this ſort of manure. Suppoſing that the bad effects which have been attributed to it, when uſed in the ſtate in which it is taken out of privies, &c. are not the offspring of a prejudiced imagination, they may have ariſen from its having been made uſe of at an improper time, or in too great quantity; or from its having been applied to a ſoil and for the cultivation of plants to which it was not adapted; for we know that the exceſs of any kind of manure changes the ſmell and taſte of plants, and the ſame effect is produced by watering them too frequently. Striking examples of this change are ſeen in the ſtrawberry and in the violet, when ſuch as have grown in the woods are compared to thoſe produced from ſome of our over-manured gardens; alſo in the lettuce, and ſome other plants, when thoſe raiſed for ſale by the gardeners about Paris are compared to thoſe of ſome particular kitchen gardens. In the markets of ſome cities, the carrots, turnips, and potatoes of the fields, are preferred to the ſame kind of roots cultivated by the gardeners (A); for though the laſt are of a larger ſize, they have not ſo good a flavour. Some vegetables, therefore, are like certain wild ſpecies of the animal kingdom; they reſiſt every kind of culture, as thoſe animals reſiſt every effort to tame them.

Manure.

"Although experience has taught the Flemiſh farmers, that excrementitious ſubſtances are more active in their natural ſtate than when dried, yet it cannot be denied that drying them, and reducing them into powder, is ſometimes very advantageous, becauſe in that ſtate they are much leſs offenſive, are eaſily tranſported to any diſtance, and may be uſed when moſt convenient or moſt proper. In many cities the inhabitants pay to have their privies emptied: in other places, thoſe who empty them pay for their contents; and it would aſtoniſh any one to be told how great a revenue is produced in the city of Liſle in Flanders by the ſale of this kind of manure. I am, however (ſays our author), far from thinking that it is right, in all caſes, to employ it in the above mentioned ſtate of concentration; it would be better, in my opinion, to follow the example of the Flemiſh farmers, who uſe it the firſt year for the cultivation of plants for oil, or for hemp or flax; and the ſecond year for the beſt kinds of grain: thus obtaining two crops, inſtead of one, without any farther preparation of the land. What is ſaid above may be applied alſo to the manures produced from the dung of cattle, poultry, &c. (particularly to pigeons dung, the moſt powerful manure of its kind), all which, by being dried and powdered before they are uſed, loſe a great portion of their activity. From theſe obſervations another fact may be deduced, namely, that manure ſhould not be taken from the place where it has been thrown together until the ſeaſon of the year and the ſtate of the land are ſuch that it may be put into the ground as ſoon as it is brought to it. In ſome diſtricts a very injurious cuſtom prevails of carrying the manure into the fields, and leaving it there formed into ſmall heaps, expoſed for ſome days to the elements; during which time, either the ſun and wind dry up its natural moiſture, leaving a maſs which is much leſs active; or the rain diſſolves and carries away the extractive part impregnated with the ſalt. This kind of brine, which is the moſt powerful part of the manure, penetrates the earth to a conſiderable depth, and ſhews (by the thick tufts which ariſe in thoſe places, and which produce more ſtraw than grain) that manure ought to be put into the ground as ſoon as it is brought to it, becauſe it then poſſeſſes its full force and effect, and conſequently would be then uſed to the greateſt advantage.

"We have always at hand the means of compoſing, from a great variety of vegetable and animal ſubſtances, ſuch manures as, when brought into a proper ſtate, and mixed with land, contribute to its fertility. Chemiſtry alſo offers to us a number of ſubſtances, which, although when uſed ſeparately they tend to diminiſh the fertiliſing quality of the earth, are yet capable, by being combined, of forming excellent manures; ſuch, for inſtance, is that ſaponaceous combination which is produced from a mixture of potaſh, oil, and earth. What an advantage it would be, if, inſtead of being ſparing of manure, the inhabitants of the country would endeavour to increaſe the number of theſe reſources, and to render them more beneficial, by employing them in a more

(A) We believe they are univerſally preferable.

Mason. the year 1779, when the city of London and some other commercial towns, agreed to present their petitions to parliament for a more economical expenditure of the public money, and a more equal representation of the people, Mr Mason came forward, and took an active part in promoting these designs, as one who was convinced of their importance and necessity. When the county of York assembled, on the 30th of December 1779, and resolved unanimously, "that a committee of correspondence should be appointed, for the effectually promoting the object of the petition then agreed to, and also to prepare a plan of *association* to support that laudable reform, and such other measures as may conduce to restore the *freedom of parliament*," he was chosen upon the committee, and was consulted with, or assisted in drawing up those various high-spirited resolutions and addresses to the public, for which the Yorkshire committee was so celebrated; and which was afterwards generally adopted by the other associated bodies of reformers. This part of his conduct is surely entitled to no praise. Thinking as we do of the parliamentary reformers, we cannot but regret that a man of Mr Mason's talents and virtues should have embarked in their dangerous pursuits; and though we perceived less hazard in those pursuits than we do, we should still consider them as unsuitable to the character of a clergyman. Our author, however, was of a different opinion. In reply to a censure passed by a dignified clergyman on the political conduct of himself and some of his reverend brethren, he published, without his name indeed, a spirited defence of their proceedings and designs in some of the country papers. The York committee, too, at its next meeting, resolved, "that a Protestant, by entering into holy orders, does not abandon his civil rights;" they also resolved, "that the thanks of the committee be given to those reverend gentlemen who, thus preferring the public good to their own private emoluments, have stood forth the firm friends to the true interests of their country."

Mr Mason, however, showed, by his subsequent conduct, that however earnestly he might wish for what he doubtless considered as an expedient reform in the commons-house of Parliament, he was firmly attached to the British constitution He was indeed a whig; but he was a whig of the old school. In the beginning of 1794, when the reformers had betrayed the principles of French democrates, he deserted them, and ranged himself under the banners of the servants of the crown; and for this conduct, which was certainly consistent, he has been plentifully traduced by our Jacobin journalists as an alarmist, who not only deserted his old friends, but ascribed to them a certain degree of guilt and political depravity.

The death of this great and good man, which happened in April 1797, was occasioned neither by age nor by inveterate disease. As he was stepping into his chariot, his foot slipped, and his shin grazed against the step. This accident had taken place several days before he paid the proper attention to it; and on April the 3d a mortification ensued, which, in the space of forty-eight hours, put a period to his life.

That he was a scholar and a poet of high eminence is universally acknowledged; and we are assured, that his posthumous works, when published, will not detract from his living fame. In private life, though he affect-perhaps too much the fastidious manners of Mr Gray, whose genius he estimated with a degree of enthusiasm amounting almost to idolatry, his character was distinguished by philanthropy and the most fervid friendships; and he may be considered as a man who merits to be ranked with the ablest supporters of British liberty and British morals.

Masonry. FREE MASONRY, is a subject which, after the copious detail given in the *Encyclopædia* of its lodges, and wardens, and grand masters, we should not have resumed in this place, but to warn our countrymen against the pernicious superstructures which have been raised by the French and Germans on the simple system of British masonry.

Much falsehood is current respecting the origin and antiquity of the masonic associations. That the Dionysiacs of Asia Minor were a society of architects and engineers, who had the exclusive privilege of building temples, stadia, and theatres, under the mysterious tutelage of Bacchus, seems to be unquestionable. "We are also certain, that there was a similar trading association during the dark ages in Christian Europe, which monopolized the building of great churches and castles, and enjoyed many privileges under the patronage of the various sovereigns. Circumstances (says Dr Robison), which it would be tedious to enumerate and discuss, continued this association longer in Britain than on the continent;" but there is no good evidence, that, anterior to the year 1648, any man sought admission into it, who was not either a builder by profession, or at least skilled in the science of architecture. At that period, indeed, Mr Ashmole, the famous antiquary (see ASHMOLE, *Encycl.*), was admitted into a lodge at Warrington, together with his father-in-law Colonel Mainwaring; and these are the first distinct and unequivocal instances that we have in Britain of men unconnected with the operative masons being received into their mysterious fraternity. The secrecy, however, of the lodges, made them fit places for the meetings of the royalists; and accordingly many royalists became free masons. "Nay, the ritual of the master's degree seems to have been formed, or perhaps twisted from its original institution, so as to give an opportunity of sounding the political principles of the candidate, and of the whole brethren present. For it bears so easy an adaptation to the death of the king, to the overturning of the venerable constitution of the English government of three orders by a mean democracy, and its re-establishment by the efforts of the loyalists, that this would start into every person's mind during the ceremonial, and could hardly fail to shew, by the countenances and behaviour of the brethren, how they were affected."

This supposition receives much countenance from the well known fact, that "Charles II. was made a mason, and frequented the lodges. It is not unlikely, that besides the amusement of a vacant hour, which was always agreeable to him, he had pleasure in meeting with his loyal friends, and in the occupations of the lodge, which recalled to his mind their attachment and services. His brother and successor James II. was of a more serious and manly cast of mind, and had little pleasure in the frivolous ceremonies of masonry. He did not frequent the lodges. But, by this time, they were the resort of many persons who were not of the profession, or members of the trading corporation. This circum-

stance,

Masonry. ſtance, in all probability, produced the denominations of *free* and *accepted* maſons. A perſon who has the privilege of working at any incorporated trade, is ſaid to be a *freeman* of that trade. Others were *accepted* as brethren, and admitted to a kind of honorary freedom; as is the caſe in many other trades and incorporations, without having (as far as we can learn for certain) a legal title to earn a livelihood by the exerciſe of it."

It was not till ſome years after this period that the lodges made open profeſſion of the cultivation of general benevolence, and that the grand aim of the fraternity was to enforce the exerciſe of all the ſocial virtues. The eſtabliſhment of a fund for the relief of unfortunate brethren did not take place till the very end of the laſt century; and we may preſume, that it was brought about by the warm recommendations of ſome benevolent members, who would naturally enforce it by addreſſes to their aſſembled brethren. Hence the probable origin of thoſe philanthropic diſcourſes, which are occaſionally delivered in the lodges by one of the brethren as an official taſk.

The boaſted philanthropy of maſons ſerves, however, another purpoſe. The inquiſitive are always prying and teazing, eager to diſcover the ſecrets of their neighbours; and hence the brethren are induced to ſay, that univerſal beneficence is the great aim of the order, for it is the only point on which they are at liberty to ſpeak. They forget, that univerſal beneficence and philanthropy are inconſiſtent with the excluſive and monopolizing ſpirit of an aſſociation, which not only confines its benevolence to its own members (like any other charitable aſſociation), but hoards up in its boſom ineſtimable ſecrets, whoſe natural tendency, they ſay, is to form the heart to this generous and kind conduct, and inſpire us with love to all mankind. The profane world cannot ſee the beneficence of concealing from public view a principle or a motive which ſo powerfully induces a maſon to be good and kind. The brother ſays, that publicity would rob it of its force; and we muſt take him at his word; and our curioſity is ſo much the more excited, to learn what are the ſecrets which have ſo ſingular a quality; for they muſt be totally unlike the principles of ſcience, which produce their effects only when made public.

From this account of maſonry, it would appear to have been at firſt a loyal aſſociation, and as ſuch it was carried over from England to the continent; for all the maſons abroad profeſs to have received their myſteries from Great Britain. It was firſt tranſported into France by the zealous adherents of King James, who, together with their unfortunate maſter, took refuge in that country; and it was cultivated by the French in a manner ſuited to the taſte and habits of that highly poliſhed and frivolous people. To the three ſimple Britiſh degrees of *apprentice*, *fellow-craft*, and *maſter*, they gradually added degrees innumerable, all decorated with ſtars and ribbons; and into their lodges they introduced the impieties and ſeditious doctrines of Voltaire and the other philoſophiſts. Indeed, if the account which the Abbé Barruel gives of maſonry be juſt, it muſt be admitted, that even the ſecrets of the moſt ancient lodges, though in one ſenſe harmleſs and juſt, are ſo expreſſed, that they may be eaſily twiſted to very dangerous purpoſes. This author was advanced by a few friends to the degree of maſter, without being obliged to take the oath of ſecrecy and being furniſhed with the ſigns, he got admiſſion into a lodge, where he heard the ſecret regularly communicated, with all the ordinary forms, to an apprentice. "It would be uſeleſs, ſays he, to deſcribe the ceremonials and trials on ſuch occaſions; for in the firſt degrees, they are nothing more than the play of children. The grand object was the communication of the famous ſecret, when the candidate was ordered to approach nearer to the venerable. At that moment, the brethren, who had been armed with ſwords for the occaſion, drawing up in two lines, held their ſwords elevated, leaning the points towards each other, and formed what in maſonry is called the *arch of ſteel*. The candidate paſſed under this arch to a ſort of altar elevated on two ſteps, at the fartheſt end of the lodge. The maſter, ſeated in an arm chair, or a ſort of throne, behind this altar, pronounced a long diſcourſe on the inviolability of the ſecret which was to be imparted, and on the danger of breaking the oath which the candidate was going to take. He pointed to the naked ſwords, which were always ready to pierce the breaſt of the traitor; and declared to him that it was impoſſible to eſcape their vengeance. The candidate then ſwore, "that rather than betray the ſecret, he contented to have his head cut off, his heart and entrails torn out, and his aſhes caſt before the winds." Having taken the oath, the maſter ſaid the following words to him: "My dear brother, the ſecret of maſonry conſiſts in theſe words, EQUALITY AND LIBERTY; *all men are equal and free; all men are brethren.*" The maſter did not utter another ſyllable, and every body embraced the new *brother equal and free*. The lodge broke up, and we gayly adjourned to a maſonic repaſt."

In the Britiſh lodges, the author admits, that no other interpretation is given to this famous ſecret, than that, as all men are children of one common parent, and creatures of the ſame God, they are in duty bound to love and help each other as brethren; but he contends, that in France it was differently interpreted; and he ſupports his opinion by the following arguments:

On the 12th of Auguſt 1792, Louis XVI. was carried a priſoner to the tower of the *temple*, ſo called becauſe it formerly belonged to the knights templars. On that day, the rebel aſſembly decreed, that to the date of *liberty* the date of *equality* ſhould be added in future in all public acts; and the decree itſelf was dated the fourth year of *liberty*, the firſt year and firſt day of *equality*. It was on that day, for the firſt time, that the ſecret of free-maſonry was made public; that ſecret ſo dear to them, and which they preſerved with all the ſolemnity of the moſt inviolable oath. At the reading of this famous decree, they exclaimed, "We have at length ſucceeded, and France is no other than an immenſe lodge. The whole French people are free maſons, and the whole univerſe will ſoon follow their example."

"I witneſſed (ſays our author) this enthuſiaſm; I heard the converſations to which it gave riſe; I ſaw maſons, till then the moſt reſerved, who freely and openly declared, 'Yes, at length the grand object of free-maſonry is accompliſhed, EQUALITY and LIBERTY; *all men are equal and brothers; all men are free.* That was the whole ſubſtance of our doctrine, the object of our wiſhes, *the whole of our grand ſecret!*'"

This is a very ſerious charge againſt the original ſociet

Masonry. cret of masonry, as it was understood in France; and though the author does not bring it directly against the same secret as understood in Britain, he yet seems to say, that in all lodges, the following question is put to the candidate before he is entrusted with any secret:—"Brother, are you disposed to execute all the orders of the grand-master, though you were to receive contrary orders from a king, an emperor, or any other sovereign whatever?" And as the brother is obliged to promise this unlimited obedience, it is easy to conceive how much a traiterous conspiracy may be promoted by means of mason lodges. The allegorical story which is told at the conferring of the degree of master, is capable of various and even contrary interpretations; for though in this country it was originally rendered subservient to the purposes of the royalists, in the occult lodges on the continent it has been made the vehicle of treason and impiety.

When the degree of master-mason is to be conferred, the lodge is hung round with black. In the middle is a coffin covered with a pall, the brethren standing round it in attitudes denoting sorrow and revenge. When the new adept is admitted, the master relates to him the following history or fable:

"Adoniram presided over the payment of the workmen who were building the temple by Solomon's orders. They were three thousand workmen. That each one might receive his due, Adoniram divided them into three classes, apprentices, fellow crafts, and masters. He entrusted each class with a word, signs, and a gripe, by which they might be recognised. Each class was to preserve the greatest secrecy as to these signs and words. Three of the fellow-crafts, wishing to know the word, and by that means obtain the salary, of master, hid themselves in the temple, and each posted himself at a different gate. At the usual time when Adoniram came to shut the gates of the temple, the first of the three met him, and demanded the *word of the masters;* Adoniram refused to give it, and received a violent blow with a stick on his head. He flies to another gate, is met, challenged, and treated in a similar manner by the second: flying to the third door, he is killed by the fellow-craft posted there, on his refusing to betray the word. His assassins buried him under a heap of rubbish, and marked the spot with a branch of acacia.

"Adoniram's absence gave great uneasiness to Solomon and the masters. He is sought for every where: at length one of the masters discovers the corpse, and, taking it by the finger, the finger parted from the hand; he took it by the wrist, and it parted from the arm; when the master, in astonishment, cried out, *Mac Benac;* which the craft interprets by "*the flesh parts from the bones.*"

"Lest Adoniram should have revealed the *word*, the masters convened and agreed to change it, and to substitute the words *Mac Benac;* sacred words, that free-masons dare not pronounce out of the lodges, and there each only pronounces one syllable, leaving his neighbour to pronounce the other."

The history finished, the adept is informed, that the object of the degree he has just received is to recover the word lost by the death of Adoniram, and to revenge this martyr of the masonic secrecy. The generality of masons, looking upon this history as no more than a fable, and the ceremonies as puerile, give themselves very little trouble to search farther into these mysteries.

These sports, however, assume a more serious aspect when we arrive at the degree of elect (*Elu*). This degree is subdivided into two parts; the first has the revenging of Adoniram for its object, the other to recover the *word*, or rather the sacred doctrine which it expressed, and which has been lost.

In this degree of elect, all the brethren appear dressed in black, wearing a breast-piece on the left side, on which is embroidered a death's head, a bone, and poignard, encircled by the motto of *Conquer or die.* The same motto is embroidered on a ribband which they wear in saltier. Every thing breathes death and revenge. The candidate is led into the lodge blindfolded, with bloody gloves on his hands. An adept with a poignard in his hand threatens to run him through the heart for the crime with which he is accused. After various frights, he obtains his life, on condition that he will revenge the father of masonry in the death of his assassin. He is shewn to a dark cavern. He is to penetrate into it; and they call to him, Strike all that shall oppose you; enter, defend yourself, and avenge our master; at that price you shall receive the degree of elect. A poignard in his right hand, a lamp in his left, he proceeds; a phantom opposes his passage; he hears the same voice repeat, Strike, avenge Hiram; there is his assassin. He strikes, and the blood flows.—Strike off his head, the voice repeats; and the head of the corpse is lying at his feet. He seizes it by the hair (A), and triumphantly carries it back as a proof of his victory; shows it to each of the brethren, and is judged worthy, of the new degree.

Our author says, that he has questioned divers masons whether this apprenticeship to ferocity and murder had never given them the idea, that the head to be cut off was that of kings; but they all affirmed that such an idea had never occurred to them till the French revolution had convinced them of the fact. At this indeed we are not surprised. The assassin of Hiram is no where said to have been a king; and why should the young elect have supposed, that when stabbing that assassin, he was training to be a regicide? The ceremony, however, is certainly ferocious in the highest degree, and obviously calculated to reconcile the masons of the occult lodges to the practice of assassination at the command of their superiors; and when it is remembered, that they are bound to pay obedience to those unseen superiors even against their lawful sovereigns, the atrocities of the revolution would naturally make them interpret this shocking ceremony as it is interpreted by the Abbé.

It was the same with respect to the religious part of this degree, where the adept is at once pontiff and sacrificer with the rest of the brethren. Vested in the ornaments of the priesthood, they offer bread and wine, according to the order of Melchisedec. The secret object of this ceremony is to re-establish religious equality, and to exhibit all men equally priests and pontiffs, to recal the brethren to natural religion, and to persuade them that the religion of Moses and of Christ had violated religious equality and liberty by the distinction of

(A) The reader may easily conceive that this corpse is no more than a mannikin containing bladders full of blood.

of priests and laity. It was the revolution again which opened the eyes of many of the adepts, who then owned that they had been dupes to this impiety, as they had been to the regicide essay in the former part.

Our author treats the fraternity of the occult lodges through the higher degrees of Scotch masonry, those of the Rosicrucians, and that of the knights Kadosch; and sums up his account in the following terms:

"In the two first degrees, that is to say, in those of *apprentice* and *fellow-craft*, the sect begins by throwing out its equality and liberty. After that, it occupies the attention of its novices with puerile games of fraternity or masonic repasts; but it already trains its adepts to the profoundest secrecy by the most frightful oaths.

"In that of *master*, it relates the allegorical history of Adoniram, who is to be avenged; and of the *word*, which is to be recovered.

"In the degree of *elect*, it trains the adepts to vengeance, without pointing out the person on whom it is to fall. It carries them back to the time of the patriarchs, when, according to them, men knew no religion but that of nature, and when every body was equally priest and pontiff. But it had not as yet declared that all religion revealed since the time of the patriarchs was to be thrown aside.

"This last mystery is only developed in the Scotch degrees. There the brethren are declared free: The word so long sought for is, Deism; it is the worship of Jehovah, such as was known to the philosophers of nature. The true mason becomes the pontiff of Jehovah; and such is the grand mystery by which he is extricated from that darkness in which the prophane are involved.

"In the degree *Rosæ Crucis*, he who wrested the *word*, who destroyed the worship of Jehovah, is Christ himself, the author of Christianity; and it is on the Gospel and on the Son of Man that the adept is to avenge the brethren, the pontiffs of Jehovah.

"At length, on his reception as Kadosch, he learns that the assassin of Adoniram is the king, who is to be killed to avenge the grand master Molay, and the order of the masons successors of the knights templars. The religion which is to be destroyed to recover the *word*, or the true doctrine, is the religion of Christ, founded on revelation. This word in its full extent is *equality* and *liberty*, to be established by the total overthrow of the altar and the throne.

"Such are the incipient degrees, the process, and the whole system of masonry; it is thus that the sect, by its gradual explanation of its twofold principle of *equality* and *liberty*, of its allegory of the founder of masonry to be avenged, of the word to be recovered, leading the adepts from secret to secret, at length initiates them into the whole Jacobinical code of revolution."

If this account of masonry be not greatly exaggerated, what are we to think of those men among ourselves, who, since the publication of the Abbé Barruel's book and Dr Robison's, have displayed a zeal for the propagation of their mysteries, by which they seemed not to be formerly actuated, and to which the importance of the business that, by their own account, is transacted in the lodges, cannot be thought to bear an adequate proportion? It is not enough to say that British masonry is harmless, and that the *equality* and *liberty* taught in our lodges are the equality and liberty taught in the bible. Without directly questioning this assertion, we only beg leave to put our countrymen in remembrance, that French and German masonry, as it was derived from Britain, must have been originally as harmless as our own; and to call their attention to the monstrous superstructures of impiety and rebellion which in these countries have been raised upon our foundation. Have there been no symptoms of sedition and irreligion among us, since the commencement of the French revolution, that we should be so confident that the equality and liberty of our lodges will never degenerate into the equality and liberty of the French Jacobins? This cannot be said; for it has been proved, that there are several occult lodges in Britain; and what security have we, or what security can we receive, that their number will not increase? The legislature indeed has lately laid some salutary restraints on the meetings of masons; but such is the nature of these meetings, that nothing can effectually secure us against the introduction of the higher mysteries, but the voluntary shutting up for a time of all lodges. This has been done by the honest masons in Germany; and why may it not be done by the masons in Britain? The fund for the relief of poor brethren may surely be managed without secrecy; the signs and gripe may be communicated without the *word*, or exacting a promise of implicit obedience; and the relinquishing of the joys of a social hour would be no great sacrifice to the peace of a country.

But is British masonry really so harmless as the younger masons wish us to believe? The writer of these reflections was never initiated in its mysteries, and therefore cannot, from his own knowledge, say what is their tendency; but he has no hesitation to affirm, because he believes himself able to demonstrate, that it is grossly immoral to promise implicit obedience to unknown superiors, or to swear that one will keep inviolate a secret, to the nature of which he is an absolute stranger. He hopes, indeed, and is inclined to believe, that, in the decent lodges of Britain, the candidate is assured, before he is required to take the oath, that the secret to be communicated, and the obedience which he is to pay, militate in no respect against the civil government or the religion of his country; but still if the secret contain information of value, it is, in his opinion, sinful to keep it a secret; and he cannot conceive upon what principle a native of Britain can promise unlimited obedience to any human being. The mysteries of masonry must relate to something which is either important and laudable; frivolous, though innocent; or dangerous and immoral. To confine to a sect any information which is laudable and important, is surely not to act the part of genuine philanthropists; to administer the most tremendous oaths in the midst of frivolous amusements, is to violate one of the most sacred precepts of our holy religion; and, as no man will pretend to vindicate dangerous and immoral mysteries, masonry appears, in every point in which it can be placed, an association which no good Christian will think himself at liberty to encourage.

MASUAH (See MASSUAH, *Encycl.*) is in latitude 15° 35′ 5″ north, and in longitude 39° 36′ 30″ east of Greenwich. On the 22d of September 1769 Mr Bruce found the variation of the needle at Masuah to be 12° 43′ west.

MATMAI, or MATSUMAI, is the largest of the Kurile islands; and if it be not independent, is tributary

Mayorga, Mayow. to Japan. The capital town of the same name, Matmai, is situated on the sea-shore, on the south-west side. It was built and is inhabited by the Japanese. It is a fortified place, furnished with artillery, and defended by a numerous garrison. The island of Matmai is the place of exile for persons of distinction at Japan: it is separated from that empire by only a narrow channel, but which is considered as dangerous, because the capes, which project on both sides, render the navigation difficult. The people are said to be sensible to friendship, hospitable, generous, and humane.

MAYORGA (Martin de). See *Don Martin*, &c. in this *Suppl.*

MAYOW (John), whose discoveries in chemistry have astonished the scientific part of the public, descended, says Wood, from a genteel family living at *Bree* in the county of *Cornwall*. His father was probably a younger son, bred to business; for our author was born in Fleet-street, London, in the parish of St Dunstan's in the West. At what school he received the rudiments of his education, a circumstance which the biographers of men eminent in the republic of letters should never omit, we have not been able to learn; but on the 27th of September 1661, when he had just completed his 16th year, he was admitted a scholar of Wadham college, Oxford. Some time afterwards, on the recommendation of Henry Coventry, Esq; one of the secretaries of state, he was chosen probationer fellow of All-souls college. As Wood informs us that he had here a *Legist's place*, an expression by which we understand a law-fellowship, it is not wonderful that he took his degrees in the civil law, though physic and the physical sciences were the favourite objects of his study. He was indeed an eminent physician, practising both in London and in Bath, but in the latter city chiefly in the summer months, till the year 1679, when he died, some time during the month of September, in the house of an apothecary in York-street, Covent Garden, and was buried in the church of that parish He had been married, says Wood, a little before his death, not altogether to his content; and indeed he must have been very discontented, if he chose to die in the house of a friend rather than in his own. He published, "Tractatus quinque medico physici, 1. De salnitro; 2. De respiratione; 3. De respiratione fœtus in utero et ovo; 4. De motu musculari et spiritibus animalibus; 5. De Rachitide." These were published together in 8vo at Oxford, in 1674; but there is an edition of two of them, "De respiratione," and "De Rachitide," published together at Leyden in 1671.

The fame of this author has been lately revived and extended by Dr Beddoes, who published, in 1790, "Chemical Experiments and Opinions, extracted from a work published in the last century," 8vo; in which he gives to Mayow the highest credit as a chemist, and ascribes to him some of the greatest modern discoveries respecting air, giving many extracts from the three first of his treatises. His chief discovery was, that oxygen gas, to which he gave the name of *fire air*, exists in the nitrous acid, and in the atmosphere; which he proved by such decisive experiments, as to render it impossible to explain how Boyle and Hales could avoid availing themselves, in their researches into air, of so capital a discovery. Mayow also relates his manner of passing aeriform fluids under water, from vessel to vessel, which is generally believed to be a new art. He did not collect dephlogisticated air in vessels, and transfer it from one jar to another, but he proved its existence by finding substances that would burn in vacuo, and in water when mixed with nitre; and after animals had breathed and died in vessels filled with atmospheric air, or after fire had been extinguished in them, there was a residuum which was the part of the air unfit for respiration, and for supporting fire; and he further shewed that nitrous acid cannot be formed, but by exposing the substances that generate it to the atmosphere. Mayow was undoubtedly no common man, especially since, if the above dates are right, he was only 34 at the time of his death. But he was not so unknown as Dr Beddoes supposed; for since the repetition of the same discovery by Priestley and Scheele, reference has frequently been made by chemists to Mayow as the original inventor; thus allowing to him a species of merit, to which he has perhaps but a doubtful claim, and which, if that claim be well founded, must certainly be shared between him and Dr Hooke. See Hooke in this *Supplement*.

Mean, Measure. MEAN, in general. See *Encycl.*

Arithmetical Mean, is half the sum of the extremes. So 4 is an arithmetical mean between 2 and 6, or between 3 and 5, or between 1 and 7; also an arithmetical mean between a and b is $\frac{a+b}{2}$, or $\frac{1}{2}a+\frac{1}{2}b$.

Geometrical Mean, commonly called a mean proportional, is the square root of the product of the two extremes; so that, to find a mean proportional between two given extremes, multiply these together, and extract the square root of the product. Thus, a mean proportional between 1 and 9, is $\sqrt{1\times 9}=\sqrt{9}=3$; a mean between 2 and $4\frac{1}{2}$ is $\sqrt{2\times 4\frac{1}{2}}=\sqrt{9}=3$ also; the mean between 4 and 6 is $\sqrt{4\times 6}=\sqrt{24}$; and the mean between a and b is $\sqrt{ab}$.

Harmonical Mean. See *Harmonical Proportion*, Encycl.

Mean and Extreme Proportion, or *Extreme and Mean Proportion*, is when a line or any quantity is so divided that the less part is to the greater, as the greater is to the whole.

Mean Anomaly of a Planet, is an angle which is always proportional to the time of the planet's motion from the aphelion or perihelion, or proportional to the area described by the radius vector; that is, as the whole periodic time in one revolution of the planet, is to the time past the aphelion or perihelion, so is 360° to the mean anomaly. See Anamoly, *Encycl.*

Mean Conjunction or *Opposition*, is when the mean place of the sun is in conjunction, or opposition, with the mean place of the moon in the ecliptic.

Mean Distance of a Planet from the Sun, is an arithmetical mean between the planet's greatest and least distances.

Mean Motion, is that by which a planet is supposed to move equably in its orbit; and it is always proportional to the time.

Mean Time, or *Equal Time*, is that which is measured by an equable motion, as a clock; as distinguished from apparent time, arising from the unequal motion of the earth or sun.

Universal or Perpetual MEASURE, is a kind of

Units. of measure unalterable by time or place, to which the measures of different ages and nations might be reduced, and by which they may be compared and estimated. Such a measure would be very useful if it could be attained; since, being used at all times, and in all places, a great deal of confusion and error would be avoided.

It has been attempted, at different times and in different countries, more especially by the French, who, since the commencement of their revolutionary government, have laboured hard to obtrude their innovations in arts and science, as well as in politics, upon all nations. Proposals, however, have been made by soberer men for a standard both of weights and of measures for all nations; and some of the most rational of these shall be noticed under the word WEIGHTS in this *Supplement*.

MECHANICS.—Our readers will recollect that in the article PHYSICS, *Encycl.* we proposed to distinguish by the term *Mechanical Philosophy* that part of natural science which treats of the local motions of bodies, and the causes of those phenomena. And, although all the changes which we observe in material nature are accompanied by local motion, and, when completely explained, are the effects (perhaps very remote) of those powers of matter which we call *moving forces*, and of those alone, yet, in many cases, this local motion is not observed, and we only perceive certain ultimate results of those changes of place. This is the case (for example) in the solution of a grain of silver in a phial of aquafortis. In the beginning of the experiment, the particles of silver are contained in a small space at the bottom of the phial; but they are finally raised from the bottom, and uniformly disseminated over the whole fluid. If we fix our attention steadily on one particle, and trace it in its whole progress, we contemplate nothing but a particle of matter acted on by moving forces, and yielding to their action. Could we state, for every situation of the particle, the direction and intensity of the moving force by which it is impelled, we could construct a figure, or a formula, which would tell us the precise direction and velocity with which it changes its place, and we could delineate its path, and tell the time when it will arrive at that part of the vessel where it finally rests in perfect equilibrium. Newton having done all this in the case of bodies acted on by the moving force called gravity, has given us a complete system of mechanical astronomy. The philosopher who shall be as fortunate in ascertaining the paths and motions of the particles of silver, till the end of this experiment, will establish a system of the mechanical solution of silver in aquafortis; and the theorems and formulæ which characterise this particular moving force, or this modification of force, stating the laws of variation by a change of distance, will be the complete theory of this chemical fact. It is this modification of moving force which is usually (but most vaguely) called the *chemical affinity*, or the *elective attraction of silver and aquafortis*.

But, alas! we are, as yet, far from having attained this perfection of chemical knowledge. All that we have yet discovered is, that the putting the bit of silver into the spirit of salt will not give occasion to the exertion of this moving force; and we express this observation, by calling that unknown force (unknown, because we are ignorant of the law of its action) an *affinity*, an *elective* attraction. And we have observed many such elections, and have been able to class them, and to tell on what occasions they will or will not be exerted; and this scrap of the complete theory becomes a most valuable acquisition, and the classification of those scraps a most curious, and extensive, and important science. The chemical philosopher has also the pleasure of seeing gradual approaches made by ingenious men to the complete mechanical explanation of these unseen motions and their causes, of which he has arranged the ultimate results. Mechanics.

The ordinary chemist, however, and even many most acute and penetrating enquirers, do not think of all these motions. Familiarly conversant with the results, they consider them as principles, and as topics to reason from. They think a chemical phenomenon sufficiently explained, when they have pointed out the affinity under which it is arranged. Thus they ascribe the propagation of heat to the expansive nature of fire, and imagine that they conceive clearly how the effect is produced. But if a mathematical philosopher should say, "What is this which you call an expansive fluid? Explain to me distinctly, in what manner this property which you call expansiveness operates in producing the propagation of heat."—We imagine that the chemist would find himself put to a stand. He will then, perhaps for the first time, try to form a distinct conception of an expansive fluid, and its manner of operation. He will naturally think of air, and will reflect on the manner in which air actually expands or occupies more room; and he will thus contemplate local motion and mechanical pressure. He will find, too late, that this gives him no assistance; because the phenomena which he has been accustomed to explain by the expansiveness of fluids have no resemblance whatever to what we see result from the actual expansion of air. Experience has made him acquainted with many effects which the air produces during its expansion; but they are of a totally different kind from those which he thought that he had sufficiently explained by the expansiveness of fire. The only resemblance he observes is, that the air and the heat, which were formerly perceived only in a small space, now appear in a much larger space. The mathematician now desires him to tell in what manner he conceives this expansiveness, or this actual expansion of air or gas. The chemist is then obliged to consider the air or gas as consisting of atoms or particles, which must be kept in their present situation by an external force, the most familiar of all to his imagination, namely, pressure; and all pressures are equally fit. Pressure is a moving force, and can only be opposed to such another moving force; therefore expansiveness supposes, that the particles are under the influence of something which would separate them from each other, if it were not opposed by something *perfectly of the same kind*. It cannot be opposed by greenness, nor by loudness, nor by fear, but only by what is competent to the production of motion; and it may be opposed by any *such* natural power; therefore by gravity, or by magnetism, or electricity, or corpuscular attraction, or by an elective attraction. The chemist, being thus led to the contemplation of the phenomenon in its most simple state, can now judge with some distinctness, what is the nature of those powers with which expansiveness can be

Mechanics. be brought to co-operate or combine. And only now will he be able to speculate on the means for explaining the propagation of heat; and he will perceive, that the general laws of motion, and of the action of moving forces (doctrines which we comprehended under the title of DYNAMICS, *Suppl.*), must be resorted to for a *complete* explanation of all chemical phenomena. The same may be said of the phenomena perceived in the growth of vegetables and animals. All of them lead us ultimately to the contemplation of an atom, which is characterised by being susceptible of local motion, and requires for this purpose the agency of what we call a moving force.

We would distinguish this particular OBJECT of our CONTEMPLATION (consisting of two constituent parts, the atom and the force, related, in fact, to each other by constant conjunction) by the term MECHANISM. We conceive it to be the characteristic of what we call MATTER; and we would consider it as the most simple MECHANICAL PHENOMENON. We are disposed to think, that this moving force is as simple and uniform as the atom to which it is related; and we would ascribe the inconceivable diversity of the moving forces which we see around us to combinations of this universal force exerted by many atoms at once; and therefore modified by this combination, in the very same manner as we frequently see those seemingly different moving forces combine their influence on a sensible mass of tangible matter, giving it a sensible local motion. Having formed such notions, we would say that we do not conceive either the atom or the force as being matter, but the two thus related. And we would then say, that whatever object of contemplation does not ultimately lead us to this complex notion is IMMATERIAL; meaning by the epithet nothing more than the negation of this particular character of the object. It is equivalent to saying, that the phenomenon does not lead the mind to the consideration of an atom actuated by a moving force; that is, moved, or prevented from moving, by an opposite pressure or force.

Such is the extension which the discoveries of last century have enabled us to give to the use of the term mechanism, mechanical action, mechanical cause, &c.

The Greeks, from whom we have borrowed the term, gave it a much more limited meaning; confining it to those motions which are produced by the intervention of machines. Even many of the naturalists of the present day limit the term to those motions which are the *immediate* consequences of impulse, and which are cases of sensible motion. Thus the chemist says, that printers ink is a mechanical fluid, but that ink for writing is a chemical fluid. We make no objection to the distinction, because chemistry is really a vast body of real and important science, although we have, as yet, been able to class only very complicated phenomena, and are far from the knowledge of its elements. This distinction made by the chemists is very clear, and very proper to be kept in view; but we should be at a loss for a term to express the analogy which is perceivable between these sensible motions and the hidden motions which obtain even in the chemical phenomena, unless we give mechanism a still greater extension than the effects of percussion or impulsion.

Mechanics, in the ancient sense of the word, considers only the energy of *organa*, machines. The authors who have treated the subject systematically, have observed, that all machines derive their efficacy from a few simple forms and dispositions, which may be given to that piece of matter called the *tool*, Ὄργανον or *machine*, which is interposed between the workman or natural agent, and the task to be performed, which is always something to be moved, in opposition to resisting pressures. To those simple forms they have given the name of MECHANICAL POWERS, simple powers, simple machines.

The machine is interposed for various reasons.

1. In order to enable a natural power, having a certain determinate intensity, which cannot be increased, to balance or overcome another natural power, acting with a greater intensity. For this purpose, a piece of solid matter is interposed, connected in such a manner with firm supports, that the pressure exerted on the impelled point by the power occasions the excitement of a pressure at the working point, which is equal or superior to the resistance, arising from the work, to the motion of that point. Thus, if a rod three feet long be supported at one foot from the end to which the resistance of two pounds is applied, and if a pressure of one pound be applied to the other end of the rod, perpendicular to its length, the cohesive forces which connect the particles of the rod will all be excited, in certain proportions, according to their situation, and the supported point will be made to press on its support as much as three pounds would press on it; and a pressure in the opposite direction will be excited at the working point, equal to the pressure of two pounds. The resistance will therefore be balanced, and it will be overcome by increasing the natural power acting on the long division of the rod. This is called a LEVER. Toothed wheels and pinions are a perpetual succession of levers in one machine or mechanical power.

2. The natural power may act with a certain velocity which cannot be changed, and the work requires to be performed with a greater velocity. A machine is interposed, moveable round a fixed support, and the distances of the impelled and working points are taken in the proportion of the two velocities. Then are we certain, that when the power acts with its natural velocity, the working point is moving with the velocity we desire.

3. The power may act only in one unchangeable direction, and the resistance must be overcome in another direction. As when a quantity of coals must be brought from the bottom of a pit, and we have no power at command but the weight of a quantity of water. We let the water pull down one end of a lever, either immediately or by a rope, and we hang the coals on the other end, while the middle point is firmly supported. This lever may be made perpetual, by lapping the ropes round a cylinder which turns round an axis firmly supported. This is a FIXED PULLEY. We can set unequal powers in opposition, by lapping each rope round a different cylinder, having the same axis. This is a WINDLASS or GIN. All these forms derive their energy from the lever virtually contained in them.

Any of these three purposes may be gained by the interposition of a solid body in another way. Instead of being supported in one point, round which it is moveable, it may be supported by a solid path, along which it is impelled, and by its shape it thrusts the resisting body

body out of its way. This is the case with the WEDGE when it is employed to force up a swagging joist, or press things strongly together. If this wedge be lapped or formed round an axis, it becomes a SCREW or a SPIRAL WIPER. This is also the operation of the balance wheel of a horizontal or cylinder watch. The oblique face of the tooth is a wedge, which thrusts the edge of the cylinder out of its way. The pallet of a clock or watch is also a wedge, acted on in the opposite direction.

These are the different forms in which a solid body is interposed as a mechanic power. All are reducible to the lever and the wedge.

But there are other mechanic powers besides those now mentioned. The carmen have a way of lowering a cask of liquor into a cellar, by passing a rope under it, making the end fast to some stake close to the ground, and bringing the other end of the rope round the cask, and thus letting it slip down in the bight of the rope. In this process they feel but half of its weight, the other half being supported by the end of the rope that is fastened to the stake. This is called a PARBUCKLE by the seamen. A hanging pulley is quite the same with this more artless method. The weight hangs by the axis of the pulley, and each half of the hanging rope carries half of the weight, and the person who pulls one of them upwards acts only against half of the weight; the other being carried by the hook to which the standing rope is fastened. This mechanical power does not (as is commonly imagined) derive its efficacy from the pulley's turning round an axis. If it were made fast, or if the tackle rope merely passed through a loop of the rope which carries the weight, it would still require only half of the weight acting on the running rope to balance it. The use of the motion round an axis is merely to avoid a very great friction. When the two hanging parts of the rope are not parallel, but inclined in any angle, the force necessary for balancing the weight is to the weight as the side is to the diagonal of the parallelogram formed by the directions of the three ropes. Varignon calls this the FUNICULAR MACHINE or power. Our sailors call it the SWIGG.

We may employ the *quaqua versum* pressure of fluidity with great effect as a mechanic power. Thus, in the hydrostatic bellows described by Gravesande, § 1451, and by Desaguiliers, the weight of a few ounces of water is made to raise several hundred pounds. In like manner, Dr Wallis of Oxford, by blowing with a pipe into a bladder, raised 64 pounds lying on it. Otto Guericke of Magdeburgh made a child balance, and even overcome, the pull exerted by the emperor's six coach horses, by merely sucking the air from below a piston. Mr Bramah, ironmonger in Piccadilly, London, has lately obtained a patent for a machine acting on this principle as a press*. A piston of one-fourth of an inch in diameter, forces water into a cylinder of 12 inches diameter, and by this intervention raises the piston of the cylinder. A boy, acting with the fourth part of his strength on the small piston by means of a lever, raises 42 tons, or 94,080 libs, pressing on the great piston. It is very surprising, that this application of the *quaqua versum* pressure of fluids has been overlooked for more than a century, although the principle has been inculcated and lectured on by every itinerant teacher, and illustrated by the above mentioned experiments of Gravesande and Wallis; nay, it has been expressly taught as a mechanic power of great efficacy by the Professor of Natural Philosophy at Edinburgh every session of the college for these twenty years past, but he never thought of putting it in practice. It forms a most compendious machine of prodigious power, and is susceptible of the greatest strength. If the same multiplication of power be attempted by toothed wheels, pinions, and racks, it is scarcely possible to give strength enough to the teeth of the racks, and the machine becomes very cumbersome and of great expence. But Mr Bramah's machine may be made abundantly strong in very small compass. It only requires very accurate execution. We give it all praise; but Mr Bramah is mistaken when he publishes it as the invention or discovery of a new mechanic power: for it has been familiar to every student of mechanics and hydrostatics ever since Boyle's first publication of his hydrostatic paradoxes.

MEDICAL JURISPRUDENCE. See *MEDICINA Forensis* in this *Suppl.*

MEDICI, is the name of an illustrious family in Florence, which contributed more than perhaps any other family whatever to the revival of letters in Europe. To trace this family from its origin, or even to give biographical sketches of all the great men whom it produced, would occupy by far too great a part of our work; for, during some centuries, almost every individual of the house of Medici was distinguished among his contemporaries. That house, after having rendered itself memorable in the annals of Florence, for opposing the encroachments of the nobles on the liberties of the people, had lost much of its influence under the aristocratic government of the Albizi, when it was raised to a rank superior to what it had ever held, by

Giovanni de MEDICI, who was born in the year 1360. This man determined to restore his family to splendour; but, conscious of his critical situation, surrounded as he was by powerful rivals and enemies, he affected rather a secure privacy than a dangerous popularity. Even when raised to the office of gonfalonier, or generalissimo of the republic, he carefully avoided any desire of partaking in the magistracy, and seemed to be entirely engrossed by merchandize, which he extended from the East throughout Europe. This conduct, as on one hand it threw his enemies off their guard, on the other, enabled him to acquire an immense fortune, of which he made a proper disposition amongst all ranks of people.

Many, even of the ruling party, either gained by his liberality, or pleased with his amiable and retired conduct, proposed to the seigniory to admit him into the magistracy; and though the proposal met with great opposition, it was carried in the affirmative.

It was by rashly declaring for the plebeians against the nobles that an ancestor of Giovanni's had lost to his family their rank in the state. Giovanni, resolving not to split on the same rock, continued to affect privacy and retirement, accepting any office in the state with the utmost appearance of reluctance, and never attending at the Palazzo, unless particularly sent for by the seigniory. Rising by these means in the esteem of the people, his enemies became, of course, unpopular; and having obtained a decided superiority over his opponents, he now ventured to procure, that those taxes which the nobles had exacted with the utmost severity and partiality from the people alone, should be levied

upon

Medici. upon the two first orders, in common with the plebeians; and that a law should be ordained, by which personal property might be taxed.

The nobles seeing, with the deepest concern, their consequence so sensibly wounded, and their power so much diminished, held several consultations in private how they might effect his ruin; but their want of unanimity prevented any thing decisive from being carried into execution. The people, alarmed for the safety of their leader and patron, offered him the sovereignty, which his relations and friends urged him to accept; but this his prudence forbad him to take, as with the title of lord he would have gained also that of tyrant. Thus, by his singular prudence, he died possessed of all the power of the state, with the affectation of being the most disinterested citizen in the commonwealth. His death happened in the year 1428.

Giovanni was graceful in his person, and his affability to all established his character for moderation. His extensive knowledge and pleasantry made his company eagerly sought. As all his actions were placid and serene, he was not in want of that trumpet of sedition, popular declamation, which he never attempted. Much to his honour, his elevation was not procured even by the banishment of a single individual; a circumstance until then unknown in Florence, where every new administration was marked with the ruin of families, and by scaffolds stained with blood.

"The maxims (says Mr Roscoe) which, uniformly pursued, raised the house of Medici to the splendour which it afterwards enjoyed, are to be found in the charge given by this venerable old man, on his deathbed, to his two sons Cosmo and Lorenzo. 'I feel (said he) that I have lived the time prescribed me. I die content, leaving you, my sons, in affluence and in health, and in such a station, that, whilst you follow my example, you may live in your native place honoured and respected. Nothing affords me more pleasure than the reflection, that my conduct has given offence to no one; but that, on the contrary, I have endeavoured to serve all persons to the best of my abilities. I advise you to do the same With respect to the honours of the state, if you would live with security, accept only such as are bestowed on you by the laws, and the favour of your fellow citizens; for it is the exercise of that power which is obtained by violence, and not of that which is voluntarily given, that occasions hatred and contention."

MEDICI (Cosmo de), the eldest son of the preceding, was born in 1389. During the life-time of his father, he had engaged himself deeply, not only in the extensive commerce by which the family had acquired its wealth, but in the weightier matters of government. When Giovanni died he was in the prime of life; and though his complexion was swarthy, he had an agreeable person, was well made, of a proper stature, and in conversation united a happy intermixture of gravity with occasional sallies of pleasantry and repartee. His conduct was uniformly marked by urbanity and kindness to the superior ranks of his fellow-citizens, and by a constant attention to the interests and the wants of the lower class, whom he relieved with unbounded generosity. By these means he acquired numerous and zealous partizans of every denomination; but he rather considered them as pledges for the continuance of the power which he possessed, than as instruments to be employed in extending it to the ruin and subjugation of the state. An interchange of reciprocal good offices was the only tie by which the Florentines and the Medici were bound; and perhaps the long continuance of this connection may be attributed to the very circumstance of its being in the power of either of the parties at any time to have dissolved it. Medici.

But the prudence and moderation of Cosmo could not repress the ambitious designs of those rival families, who wished to possess or to share his authority. In the year 1433, Rinaldo de Albizi, at the head of a powerful party, carried the appointment of the magistracy. At that time Cosmo had withdrawn to his seat in the country, to avoid the disturbances which he saw likely to ensue; but at the request of his friends he returned to Florence, where he was led to expect such a union of parties, as might at least preserve the peace of the city. No sooner did he make his appearance in the palace, where his presence had been requested, on pretence of his being intended to share in the administration of the republic, than he was seized upon by his adversaries, and committed to prison.

The conspirators were divided in their opinions as to the disposal of their prisoner. Most of them inclined to follow the advice of Peruzzi, who recommended taking him off by poison. Cosmo, confined in the Alberzettino, a room in one of the turrets of the Palazzo, could hear this dreadful consultation, which was determining, not in what manner he should be tried, but in what manner he should be put to death; and finding that he was to die by an infusion of poison secretly administered to him, a small portion of bread was the only food which he thought proper to take.

Cosmo lived in this manner four days; and, shut up from all his kindred and friends, he soon expected to be numbered with the dead; but here, as it sometimes happens, he found relief where least expected, from the man who had been engaged to take him off. Malavolta, the keeper of the prison, either from compunction, dissatisfaction, or the youth and misfortunes of the illustrious sufferer, relented; and instead of pursuing any criminal intentions against the life of Cosmo, after upbraiding him with entertaining so unworthy an opinion of him, declared that his fears were entirely groundless. To convince him of this, he sat down, and partook of every thing the prisoner chose to eat of. The expressions of gratitude, together with his most engaging manners, and great promises, entirely won Malavolta, who, to ingratiate himself still farther in the good opinion of Cosmo, invited Fargaccio, the most celebrated wit in Florence, to dine with him the next day, from the idea that his sprightly mirth would contribute to lighten his misfortunes.

In the mean time, his brother Lorenzo, and his cousin Averardo, having raised a considerable body of men in Romagna and other neighbouring districts, and being joined by the commander of the troops of the republic, approached towards Florence to his relief. The apprehension, however, that the life of Cosmo might be endangered, if they should proceed to open violence, induced them to abandon their enterprise. At length Rinaldo and his adherents obtained a decree of the magistracy, by which Cosmo was banished to Padua for ten years, his brother to Venice for five years; and several

Medici. veral of their relations and adherents ſhared the ſame fate.

Coſmo received this determination of his judges with a compoſure that gained him the compaſſion and the admiration of many of his moſt inveterate enemies. He would gladly have left the city purſuant to his ſentence; but he was detained by his enemies till their authority ſhould be eſtabliſhed: and it was not till he thought of bribing the gonfalonier, and another creature of Rinaldo's, that he was privately taken from his confinement, and conducted out of Florence.

Padua, to which he was confined by his ſentence, was in the dominions of Venice; but before he could reach that place, he received a deputation from the ſenate, the purport of which was to condole with him for his misfortunes, and to promiſe him their protection and aſſiſtance in whatever he ſhould deſire. He experienced the treatment of a prince rather than that of an exile. Nor were that wiſe people without good reaſons for ſuch a conduct. Venice had long regarded Florence as her rival in commerce, and hoped, by conferring upon Coſmo the moſt flattering diſtinctions, to prevail upon him to reſide there in future; prudently ſuppoſing, that the manufactories of Florence, and the great commerce the Medici had carried on throughout Italy, and extended far beyond it to the wealthieſt kingdoms in Europe, would become their own by enrolling him amongſt their ſubjects.

The readineſs with which Coſmo had given way to the temporary clamour raiſed againſt him, and the reluctance which he had ſhewn to renew thoſe rencounters which had ſo often deluged the ſtreets of Florence with blood, gained him new friends, even during his exile. The utmoſt exertions of his antagoniſts could not long prevent the choice of ſuch magiſtrates as were known to be attached to the cauſe of the Medici; and no ſooner did they enter on their office, than Coſmo and his brother were recalled, and Rinaldo with his adherents were compelled to quit the city. This event took place about a year after the baniſhment of Coſmo.

The ſubſequent conduct of this great man (for great all allow him to have been) has been painted in different colours by different writers. Mr Noble, after Machiavel, compares his cruelties to his fallen foes with thoſe of Sylla and Octavius to the partizans of Marius and Brutus; whilſt Roſcoe repreſents his conduct as in a high degree amiable and generous. It appears to us evident, from his own words, that he had exerciſed ſome cruelties on his exiled enemies; for when one of them wrote to him, that "the hen was hatching," he replied, "She will have but a bad time of it, ſo far from her neſt." When ſome other exiles acquainted him that "they were not aſleep," he anſwered, "he could eaſily believe that, for he thought he had ſpoiled their ſleeping." At another time, ſome of the citizens remonſtrated with him upon the odiouſneſs of his conduct in baniſhing ſo many perſons; telling him, "the republic would be extremely weakened, and God offended, by the expulſion of ſo many good and pious men as he was ſending into baniſhment." His anſwer was, "It would be better for the republic to be weakened than utterly ruined; that two or three yards of fine cloth made many a one look like a good man; but that ſtates were not to be governed or maintained by counting a ſtring of beads, and mumbling over a few *Pater noſters*."

From this time the life of Coſmo de Medici was an almoſt uninterrupted ſeries of proſperity. His misfortunes had taught him, that the affectation of grandeur is more dangerous in a free ſtate than uſurpation. He adopted, therefore, the dreſs, behaviour, and manners, of a private citizen. His clothes were of the ſame faſhion and materials as the reſt of the Florentines. In the ſtreets he walked alone and unguarded. His table was ſupplied from what his eſtate of Mugello produced, nor had he one ſervant more than was abſolutely neceſſary; thus endeavouring to unite the character of a prince with that of a merchant, and a private perſon in a republic. Medici.

Whilſt he rejected all offices in the magiſtracy, no buſineſs was tranſacted without its being firſt ſettled at Mugello: nor did he contract any alliances but with the ſons and daughters of the citizens of Florence; yet all foreign princes and courts paid his children the reſpect due only to thoſe of ſovereigns; and the family of Coſmo received educations equal to thoſe of the greateſt potentates.

A proper judgment may be formed of his immenſe traffic, and the prodigious advantages accruing from it: For though a private citizen of Florence only, yet he poſſeſſed at one time more money than what was in all the treaſuries of the different ſovereigns in Europe. When Alfonſo king of Naples leagued with the Venetians againſt Florence, Coſmo called in ſuch immenſe debts from thoſe places, as deprived them of reſources for carrying on the war. During the conteſt between the houſes of York and Lancaſter, he furniſhed Edward IV. with a ſum of money ſo great, that it might almoſt be conſidered as the means of ſupporting that monarch on the throne.

In his public and private charities, in the number and grandeur of the edifices he erected, not only in Florence, but in the moſt diſtant parts of the world, and in the foundations which he endowed, he ſeemed to more than vie with majeſty. He ſupplied moſt of the exigencies of the ſtate from his private purſe; and there were few citizens that had not experienced his liberality, and many without the leaſt application, particularly the nobles.

But in nothing did his munificence produce ſo much good to the world, or acquire ſuch honour to himſelf, as when it was exerted for the promotion of ſcience, and the encouragement of learned men; and upon nothing did Coſmo delight ſo much to exert it. The ſtudy of the Greek language had been introduced into Italy towards the latter part of the preceding century; but it had again fallen into neglect. After a ſhort interval, an attempt was made to revive it, by the intervention of Emanuel Chryſoloras, a noble Greek, who taught that language at Florence, and other cities of Italy, about the beginning of the 15th century. His diſciples, who were numerous and reſpectable, kept the flame alive till it received new aid from other learned Greeks, who were driven from Conſtantinople by the dread of the Turks, or by the total overthrow of the Eaſtern Empire. To theſe illuſtrious foreigners, as well as to the learned Italians, who ſhortly became their ſucceſsful rivals, even in the knowledge of their national hiſtory and language, Coſmo afforded the moſt liberal ſupport and protection. The very titles of the works of ancient authors, which were brought to light by his munificence,

Medici. nificence, would extend this article beyond its proper limits. Such, indeed, was the eſtimation in which theſe works were then held in Italy, that a manuſcript of the hiſtory of Livy, ſent by Coſmo de Medici to Alfonſo king of Naples, with whom he was at variance, conciliated the breach between them.

As the natural diſpoſition of Coſmo led him to take an active part in collecting the remains of the ancient Greek and Roman writers, ſo he was enabled by his wealth, and by his extenſive mercantile intercourſe with different parts of Europe and of Aſia, to gratify a paſſion of this kind beyond any other individual. To this end he laid injunctions on all his friends and correſpondents, as well as on the miſſionaries and preachers who travelled into the remoteſt countries, to ſearch for and procure ancient manuſcripts, in every language, and on every ſubject. The ſituation of the Eaſtern Empire, then falling into ruins, afforded him an opportunity of obtaining many ineſtimable works in the Hebrew, Greek, Chaldaic, Arabic, and other eaſtern languages. From theſe beginnings aroſe the celebrated library of the Medici; which, after various viciſſitudes of fortune, and frequent and conſiderable additions, has been preſerved to the preſent times under the name of the *Bibliotheca Mediceo Laurentiana.*

Nor was Coſmo a mere collector of books, he was himſelf, even in old age, a laborious ſtudent. Having been ſtruck with the ſublime ſpeculations of Plato, which he had heard detailed in lectures by a Greek monk, who had come from Conſtantinople to the council of Florence, he determined to found an academy for the cultivation of that philoſophy. For this purpoſe he ſelected Marſilio Ficino, the ſon of his favourite phyſician, and deſtined him, though very young, to be the ſupport of his future eſtabliſhment. The education of Ficino was entirely directed to the Platonic philoſophy; nor were the expectations which Coſmo had formed of him diſappointed. The Florentine academy was ſome years afterwards eſtabliſhed with great credit, and was the firſt inſtitution in Europe for the purſuit of ſcience, detached from the ſcholaſtic method then univerſally adopted. It is true, the fanciful doctrines of Plato are as remote from the purpoſes of life as the ſubtleties of Ariſtotle; but, by dividing the attention of the learned between them, the dogmas of the Stagyrite were deprived of that ſervile reſpect which had ſo long been paid to them, and men learned by degrees to think for themſelves.

The foſtering hand of Coſmo was held out to art as well as to ſcience; and architecture, ſculpture, and painting, all flouriſhed under his powerful protection. The countenance ſhewn by him to theſe arts was not ſuch as their profeſſors generally receive from the great. It was not conceded as a bounty, nor received as a favour, but appeared in the friendſhip and equality that ſubſiſted between the artiſt and his patron; and the ſums of money, which Coſmo expended on pictures, ſtatues, and public buildings, appear almoſt incredible.

Coſmo now approached the period of his mortal exiſtence; but the faculties of his mind remained unimpaired. About twenty days before he died, he ſent for Ficino, and enjoined him to tranſlate from the Greek the treatiſe of Xenocrates on death. Calling into his chamber his wife and his ſon Piero, he entered into narrative of all his public tranſactions; in which he gave a full account of his extenſive mercantile connections, and adverted to the ſtate of his domeſtic concerns. To Piero he recommended a ſtrict attention to the education of his ſons; and requeſted, that his funeral might be conducted with as much privacy as poſſible. He died on the firſt of Auguſt 1464, at the age of 75 years, deeply lamented by a great majority of the citizens of Florence. Their eſteem and gratitude had indeed been fully ſhewn ſome time before, when, by a public decree, he was honoured with the title of *Pater Patriæ*, an appellation which was inſcribed on his tomb; and which, as it was founded, ſays Roſcoe, on real merit, has ever ſince been attached to the name of Coſmo de Medici.

Medici (Lorenzo de), juſtly ſtyled the *magnificent*, was the grandſon of Coſmo, and about 16 years of age when his grandfather died. His father Piero de Medici, though poſſeſſed of more than ordinary talents, as well as of a very conſiderable ſhare of worth, was, from various circumſtances, little qualified to maintain the influence which his family had gained in the republic of Florence. From very early life he had been tortured by the gout; and almoſt uninterrupted pain had made him peeviſh. Such a diſpoſition was not calculated to retain the affections of the giddy Florentines, or to perſuade republicans that they were free, while they ſubmitted to the government of a ſingle individual. All this Coſmo had foreſeen, and had done what wiſdom could do to preſerve to his family that aſcendency in the republic which he had himſelf acquired. He exhorted Piero to beſtow the utmoſt care on the education of his ſons, of whoſe capacity he expreſſed a high opinion; he recommended to him Diotiſalvo Neroni, a man whom he had himſelf raiſed from obſcurity to an eminent rank, as a counſellor, in whoſe wiſdom and fidelity he might place the utmoſt confidence: and to bind the inhabitants of Florence to the houſe of Medici by the ſtrongeſt of all ties, he had diſtributed among them, under the denomination of loans, immenſe ſums, which he knew they would not ſoon be able to repay.

Piero paid the utmoſt deference to the dying injunctions of his father. He had himſelf an ardent love of letters; and under the eye of the venerable Coſmo, he had given his two ſons, Lorenzo and Juliano, the beſt poſſible domeſtic education. In the Greek language, in ethics, and in the principles of the Ariſtotelian philoſophy, Lorenzo, the eldeſt, had the advantage of the precepts of the learned Argyropylus (A), and in thoſe of the Platonic ſect he was ſedulouſly inſtructed by Marſilio Ficino (ſee Ficinus, *Encycl.*); but for his moſt valuable accompliſhments he was not indebted to any preceptor. To complete his education, however, it was judged expedient that he ſhould viſit ſome of the principal courts of Italy; and very ſoon after the death of his grandfather, he repaired to Rome, Bologna, Ferrara, Venice, and Milan, where he gained the eſteem of all whoſe eſteem was of value.

Thus

(A) This man had fled from Conſtantinople, when it was taken by the Turks, to Florence, where he was protected by Coſmo de Medici.

Thus attentive was Piero to the advice of his father with respect to the education of his eldest son; nor was he less attentive to it in the choice of his principal counsellor. He intrusted the whole of his affairs into the hands of Neroni, and gave him Cosmo's accounts to peruse and settle. That ambition, which perhaps had lain lurking in this man's mind, was now called forth, and he basely formed the scheme of ruining the son of his patron, by building upon his misfortunes his own future grandeur. For this purpose, he lamented the absolute necessity there was for an immediate call upon those who were indebted to Piero as Cosmo's representative; telling him, that a delay might subject him to the greatest inconveniences. Piero consented, though with reluctance, to his supposed friend's advice. The result was such as Neroni expected. Those who were friends of the father became enemies of the son; and had not Piero discovered the snare, and desisted from such rigorous proceedings, he might have found, when too late, that in supporting the character of the merchant, he had forgotten that of the statesman; for all the citizens of Florence were his debtors.

Soon after this, an attempt was made to assassinate Piero, by a powerful party which had always been inimical to the house of Medici; but it was defeated by Lorenzo, who displayed on that occasion a sagacity and promptitude of mind which would have done honour to the oldest statesman. A few of the conspirators were declared enemies to the state, and condemned to banishment; but by far the greater part of them were pardoned on the solicitation of Lorenzo, who declared, that "he only knows how to conquer, who knows how to forgive."

In the year 1469 Piero de Medici died; and Lorenzo succeeded to his authority as if it had been a part of his patrimony, being requested by the principal inhabitants of Florence, that he would take upon himself the administration of the republic in the same manner that his grandfather and father had done.

In the month of December 1470, a league was solemnly concluded between the pope, the king of Naples, the duke of Milan, and the Florentines, against Mahomet II. who had vowed not to lay down his arms till he had abolished the religion of Christ, and extirpated all his followers. The pope, however (Paul II.), died on the 26th of July 1471; and Sixtus IV. succeeding to the chair of St Peter, Lorenzo was deputed from Florence to congratulate him on his elevation. Two more opposite characters can hardly be conceived than those of Sixtus and Lorenzo. The former was cruel, treacherous, and sordid; the latter was merciful, candid, and generous. Yet such instances of mutual good will took place between them on this occasion, that Lorenzo, who, under the direction of his agents, had a bank established at Rome, was formally invested with the office of treasurer of the Holy See.

Pisa had been under the dominion of Florence from the year 1406, and it had acquired some celebrity on account of its academy, which had existed almost two centuries. That academy, however, had fallen into decay; and, in the year 1472, the Florentines resolved to restore it to its pristine splendour. Five citizens, of whom Lorenzo de Medici was one, were appointed to superintend the execution of their purpose; but Lorenzo, who was the projector of the plan, undertook the chief management of it; and, in addition to 6000 florins annually granted by the state, expended, in effecting his purpose, a large sum of money from his private fortune. In doing this, he only imitated the example of his father and grandfather; for in the course of 37 years, reckoning from the return of Cosmo from banishment, this illustrious family had expended on works of charity or public utility upwards of 660,000 florins. "Some persons (said Lorenzo) would perhaps be better pleased to have a part of it in their purse; but I conceive that it has been of great advantage to the public, and well laid out, and am therefore perfectly satisfied."

In the year 1474, Lorenzo incurred the displeasure of the pope for opposing some of his encroachments on the petty princes of Italy; and the revenge planned by Sixtus was of such a nature as would have disgraced, we do not say a Christian bishop, but the rudest savage. He began by depriving Lorenzo of the office of treasurer of the Roman See, which he gave to the Pazzi, a Florentine family, who, as well as the Medici, had a public bank at Rome. By this step he secured the interest of the Pazzi, who, it is probable, were to govern Florence under the pope, when Lorenzo and Juliano de Medici should be cut off, and their friends and adherents driven from the republic. The principal agent engaged in the undertaking was Franscesco Salviati archbishop of Pisa, to which rank he had lately been promoted by Sixtus, in opposition to the wishes of the Medici. The other conspirators were Giacopo Salviati, brother to the archbishop; Giacopo Poggio, one of the sons of the celebrated Poggio Bracciolini (see Poggius, *Encycl.*); Barnardo Bandini, a daring libertine, rendered desperate by the consequence of his excesses; Giovanni Battisti Montesicco, who had distinguished himself as general of the pope's armies; Antonio Maffei, a priest of Volterra; and Stephano de Bagnona, one of the apostolic scribes; with several others of inferior note. The cardinal Riario, then at Pisa, was likewise an instrument in the conspiracy; but he can hardly be considered as an agent, for he was kept ignorant of what was going on, and enjoined only to obey whatever directions he might receive from the archbishop of Pisa.

The assassination of the illustrious youths was fixed for Sunday, April 26. 1478; the place the cathedral of Florence, at the moment the host was to be elevated; and their murder was to be the signal for seizing and expelling from the walls of the city all their relations and friends. What a transaction this for one who presumed to style himself the vicar of Christ, the common father of Christendom, to patronize!

The fatal day arrived, and Lorenzo was already in the church; but Juliano remained at home, occasioned by a slight indisposition. The conspirators, determining not to lose one of their victims, went to invite, to intreat him, to go. They embraced (B), and led him, by a tender violence, to the cathedral. The signal was given

(B) The assassins embraced Juliano, to discover whether he wore any secret armour, that they might know where to strike with the surest aim

Medic given by the elevation of the consecrated wafer; and whilst the people fell upon their knees to adore, the assassins rose, and, as was concerted, two of them, Francisco Pazzi and Barnardo Bandini, fell upon Juliano. The latter directed his poignard so truly, that it entered into the bosom of the unoffending youth, and he fell mortally wounded at his feet.

In a moment, as must be supposed, all was confusion. Lorenzo, alarmed, put himself in a posture of defence, when, in an instant, Antonio of Volterra, and Stephano a priest, the dependant of the archbishop, who, upon Giovanni Battisti's declining the infamous task, undertook his destruction, rushed upon him as their destined prey. The contest continued some time. Lorenzo had received a wound in his neck, and seemed to contend for his life in vain; but a servant, whom he had lately relieved from prison, inspired by gratitude, heroically threw himself between his beloved lord and his assassins, receiving in his body those weapons that were aimed at the breast of Lorenzo. This fidelity saved him; for by one vigorous effort he broke from Antonio and Stephano, and with a few friends rushed into the sacristy, shutting the doors behind them, which were of brass. Apprehensions being entertained, that the weapon which had wounded him was poisoned, a young man sucked the wound, endangering his own life to save that of Lorenzo.

The rage of the people to see one of their favourites expiring, and the other covered with blood, was inexpressible. The cardinal Riario found it difficult to save his life at that altar which he had stained by so horrid a deed, and to which he then fled for protection.

Whilst this infamous scene was acting in the cathedral, others of the conspirators were attempting to seize the Palazzo; but with no better success. The archbishop Salviatti, who had undertaken to head them, gave the magistrates suspicion by those violent emotions which agitated his whole frame. The nine senators who composed the magistracy, including the gonfalonier, who had been appointed by, and were, in other words, the privy council of the Medici, immediately attacked those who intended to have surprised them; and Salviatti and his followers had no sooner gained the second floor, than they found themselves prisoners.

Jacobo Pazzi soon appeared in the street, proclaiming, with exultation, the murder of Juliano; and inviting the Florentines to free themselves from the Medicean slavery; but perceiving that he was not joined by the people, the magistrates sent off 100 horse to the rescue of Lorenzo. This was the more to be commended, because they continued to be assaulted by the conspirators, who, finding their situation desperate, forced themselves to the ground floor, determining, if possible, to seize the Palazzo. The magistrates, with their attendants, acted with such resolution and valour, that as often as they gained an entrance, they drove them back, killing some of the assailants upon the spot, others they threw out of the windows upon the pavement; and to strike an awe into those that were without, they had the boldness and virtue to hang the archbishop from one of the windows, dressed as he was in his pontifical robes, with Poggio, another of the chief conspirators. Florence resounded in every part with the exclamation—Medici, Medici! down with their enemies!

Lorenzo was liberated from that part of the cathedral to which he had fled, and conveyed home in triumph, where his wounds were attended to, and where he found himself surrounded by his most valuable friends, to whom he was endeared by the shocking occurrences of the day. His partizans, however, did not spend their time only in lamentations for the death of one of the brothers, and exultations for the preservation of the other; they united in pursuing the conspirators, sparing none that fell into their hands. Jacobo Pazzi was taken flying with his forces into Romania, and immediately hung. An officer of the pope's, who commanded a brigade under count Hirronimo, had alone the favour of decapitation. Bandini fled privately to Pisa, thence to Naples, and, lastly, to Constantinople; but Mahomet, to oblige Lorenzo, seized, and sent him back; and he was hung out of the same window from which the archbishop had suffered. An embassy was sent from Florence to thank the sultan in the name of the republic.

Throughout the whole of this just but dreadful retribution, Lorenzo had exerted all his influence to restrain the indignation of the populace. He entreated that they would resign to the magistrates the task of ascertaining and of punishing the guilty, lest the innocent should be incautiously involved in destruction; and his appearance and admonitions had an instantaneous effect. By his moderation, and even kindness to the relatives of the conspirators, he sought to obliterate the remembrance of past disturbances; and by his interference, even the survivors of the Pazzi were restored to their honours, of which they had been deprived by a decree of the state.

The generosity and moderation of Lorenzo had no effect on the temper of Sixtus, who solemnly excommunicated him, the gonfalonier, the magistrates, and their immediate successors; and in the bull which he issued on this occasion, he styles Lorenzo de Medici "the child of iniquity, and the nursling of perdition!" Not content with this ebullition of resentment, he suspended the bishops and clergy of the Florentine territories from the exercise of their spiritual functions; thus laying the whole republic under an interdict. This had been a formidable weapon in the hands of his predecessors, who had, by means of it, overawed the most powerful monarchs; but the general character of Sixtus was so infamous, and his present injustice so manifest, that by the exertions of the bishop of Arezzo, a convocation was held in the cathedral church of Florence, in which Sixtus was accused of *fornication* and *adultery*, with other infamous vices; declared to be the principal instigator of the conspiracy against the Medici; and the sentence of excommunication which he had fulminated against Lorenzo and the Florentine magistrates was called in direct terms, the "execrable malediction of a damned judge (*maledictam maledictionem damnatissimi judicis*)!"

How such language could be reconciled to the notions which then prevailed of the sanctity of the pope, and the plenitude of his power, it is needless to inquire; but the reader will not be surprised that the prelates, who made use of it, paid no regard to the interdict of Sixtus. The pontiff, however, did not relax from his purpose. Whilst he brandished with one hand the spiritual weapon, which the Florentines treated with such contempt, in the other, he grasped a temporal sword, which he now openly, as he had before secretly, aimed at the breast of Lorenzo. At his instigation the king of Naples dispatched

Medici. dispatched an envoy to Florence, to require the citizens to banish Lorenzo from the Tuscan territories, if they would not incur the vengeance both of him and of the pope. These threats produced not the intended effect; for the Florentines avowed their firm resolution to suffer every extremity, rather than betray the man whom they considered as guardian of the republic. War therefore was commenced; and the republic was on the point of being ruined, when Lorenzo taking advantage of a truce, threw himself, with a resolution not to be equalled, into the hands of the king of Naples. He judged, perhaps, that any stipulations for his personal safety would be useless with a prince who had sported with honour, justice, mercy, and the most solemn treaties. But, whilst all viewed him as a victim who had devoted himself to save his country, he, by persuasive eloquence, obtained of this crafty perfidious monarch a separate peace, and returned to Florence crowned with a success that no one thought possible, and where he was received as its tutelar deity. The pope, however, continued inflexible, till a descent of the Turks upon Italy restored him to his senses, and made him willing to receive the submission of Florence, and reconcile its inhabitants to the church.

Soon after the termination of the hostilities between Sixtus and the republic of Florence, Lorenzo began to unfold plans for securing the peace of Italy, which confer the highest honour on his political life. To counterpoise all the jarring interests of the petty states of which that country was composed, to restrain the powerful, succour the weak, and to unite the whole in one firm body which might be able, on the one hand, successfully to oppose the formidable power of the Turks, and, on the other, to repel the incursions of the French and Germans, were the important ends which this great man proposed to accomplish. But before he engaged in these momentous undertakings, he had further personal dangers to encounter. By the instigation of Cardinal Riario, and some Florentine exiles, one Battista Frescobaldi, with only two assistants, undertook to assassinate him in the church of the Carmeli, on the festival of the ascension 1481; but the plot was discovered, the conspirators executed, and Lorenzo henceforth seldom went abroad without being surrounded by a number of tried friends.

Lorenzo was now at liberty to prosecute his benevolent purposes; and after contributing to the expulsion of the Turks from Italy, he set himself in good earnest to support the weak states against the encroachments of the more powerful. This necessarily embroiled the republic at one time with the pope, at another with the king of Naples; now with the Venetians, and then with the Duke of Milan: but when some exclaimed against him as being too precipitate in involving the republic in dangerous and expensive wars, he explained to them the necessity of maintaining the balance of power, if they would preserve the independence of their own state; and so completely had he made himself master of this subject, that he convinced the most incredulous of the propriety of his measures, which, in 1488, introduced general tranquillity into Italy

At this period, the city of Florence was at its highest degree of prosperity. The vigilance of Lorenzo had secured it from all apprehensions of external attack; and his acknowledged disinterestedness and moderation had almost extinguished that spirit of internal dissension for which it had been so long remarkable. The Florentines gloried in their illustrious citizen, and were gratified by numbering in their body a man who wielded in his hands the fate of nations, and attracted the respect and admiration of all Europe.

Yet amidst public affairs so intricate and so momentous, such was the capacity of this man's mind, and such his versatility of genius, that, for the greater part of his life, he carried on a commerce as extensive as that of his grandfather, whilst he afforded still greater encouragement to learning and learned men. Cosmo had greatly promoted the study of the ancient languages and ancient philosophy. Lorenzo did the same thing; but he did much more; he encouraged the cultivation of his own tongue, which had been neglected since the age of Petrarca; and by setting a great example himself, he produced a race of Italian poets, which have hardly been surpassed in any age or nation. To enumerate even the names of the elegant scholars whom he patronised, would extend this article far beyond its limits. In the academy of Pisa, of which mention has been already made, the studies were chiefly confined to the Latin language, and to those sciences of which it was the principal vehicle. At Florence the Greek tongue was taught under the sanction of a public institution, either by native Greeks or learned Italians, whose services were procured by the diligence of Lorenzo de Medici, and repaid by his bounty. He placed Michael Angelo at the head of an academy, which he erected for painting and sculpture, furnishing it with the best models of antiquity. He built and endowed a public library, and sent Lascaris, of imperial descent, to Constantinople more than once, to procure Greek manuscripts. For father Moriano, the orator, a monastery was built; and Florence owed many of her finest edifices to him. Politiano and Ficino were among his most intimate friends; and it is not perhaps too much to say, that he did more for letters and science and art than any other individual that ever existed. His own acquirements in learning were great; and his poetry, of which the reader will find many specimens in the elegant work of Roscoe, was exquisite.

Is it surprising, when we examine Lorenzo's character, that all Italy, all Christendom, even the Mahometans, gave him the most flattering marks of approbation, and strove who should oblige him most, by presenting him with whatever was rare and valuable? His palace was constantly filled with men famous in every elegant, every useful science, and the neighbouring princes flocked to it as to the temple of wisdom. The celebrated prince of Mirandola, on his account, chose Florence for his residence, and died there.

To a most engaging person was added each grace, and every accomplishment. He was the favourite of the ladies, the envy of the men, and the admiration of both. The statesman of his time; unrivalled in chivalry; one of the most eminent orators that the world has produced. His poetic merit, with his judgment in, and patronage of that art, procured him the title of "Father of the Muses." In liberality to his fellow-citizens, as well as in every other respect, except as a general, he exceeded even Cæsar himself; and had not peace been his dear delight, his talents would have made him a consummate commander. Yet with all these superior

point of accompliſhments, he did not think it beneath him to indulge in amuſements which perſons, leſs wiſe, would have thought an impeachment of their underſtanding, and he would often ſeek pleaſure in his nurſery, ſpending hours there in all the frivolous pranks of childiſh diverſion. In fine, "the gravity of his life, if compared with its levity, muſt make him appear as a compoſition of two different perſons, incompatible, and, as it were, impoſſible to be joined with the other."

Lorenzo, like moſt other great men, had wiſhed to ſpend his laſt years in the tranquillity of retirement. He therefore at an early period wound up his mercantile concerns, and divided his time between the cares of the republic at Florence, and the cultivation of his eſtates in the country. He wiſhed even to diveſt himſelf of all public concerns, and get his ſecond ſon Giovanni admitted into holy orders at the age of ſeven years, that he might be fit for eccleſiaſtical preferment before he ſhould be deprived of the protection of his father. The young eccleſiaſtic, who afterwards made ſuch a figure as Leo X. was accordingly appointed by Louis XI. of France, abbot of Fonte Dolac, before he was eight years of age; and by Innocent VIII. a cardinal, when he was little more than thirteen. This added much to the influence of the family, not only in the Tuſcan ſtates but through all Italy; and Lorenzo having introduced his eldeſt ſon into public life, and accompliſhed a marriage between him and the daughter of a noble family at Rome, thought he might commit the affairs of the republic in a great meaſure to Piero, and indulge his own taſte in the converſation of his learned friends. This dream of felicity however was not realized. Early in the year 1492, he was attacked by a diſeaſe, under which he had long laboured, with ſuch violence, that on the 8th of April he died in the midſt of his weeping friends, after having taken of them, one by one, an affectionate farewel, and given to his ſon Piero much ſalutary counſel, which he thought not fit to follow.

The character of this great and good man is developed in the detail which we have given of his conduct through life: But it may not be improper to add, that ſuch was the love and veneration of the citizens to him, that the phyſician, who had attended him on his deathbed, afraid to return to Florence, left the houſe in a ſtate of diſtraction, and plunged himſelf into a well. Throughout the reſt of Italy the death of Lorenzo was regarded as a public calamity of the moſt alarming kind. Of the arch which ſupported the political fabric of that country he had long been conſidered as the centre, and his loſs ſeemed to threaten the whole with immediate deſtruction. When Ferdinand king of Naples was informed of the event, he exclaimed, "This man has lived long enough for his own glory, but too ſhort a time for Italy."

MEDICINA FORENSIS, is a phraſe uſed in Germany to denote thoſe parts of anatomical and phyſiological knowledge, which enable phyſicians and ſurgeons to decide certain cauſes as judges in courts of juſtice. In that country it has long been law and cuſtom (if we miſtake not, by the Caroline code of Charles V.) to refer caſes of *poiſoning, child murder, rape, pregnancy, impotency, idiotiſm*, &c. to the medical faculty, which, in the univerſities and ſome other great towns, is conſtituted into a kind of court for the trial of ſuch queſtions. In this country there are no ſuch courts; but in criminal trials medical gentlemen are often called upon to deſcribe the ſymptoms of *poiſoning, child murder, rape*, &c. and therefore it becomes them to obtain an accurate knowledge of theſe ſymptoms, and to ſtore their memories with a number of minute facts, to which they may have occaſion to appeal when giving their evidence.

The importance of this ſubject induced the profeſſor of the inſtitutes of phyſic in the univerſity of Edinburgh to reſolve lately to read an annual courſe of lectures on MEDICAL JURISPRUDENCE. This, we doubt not, will prove a valuable courſe; for though it is hardly conceivable that, under the head *medical juriſprudence*, any *knowledge* can be communicated which a well educated phyſician would not neceſſarily have acquired, without attending ſuch a courſe; yet it is very obvious, that the recollection of the young phyſician may receive great aid from his liſtening to the well arranged lectures of an accurate profeſſor. From theſe lectures he may ſtore his mind with a collection of aphoriſms which ſhall be always ready on the day of examination; or the lectures themſelves may be delivered in queſtions and anſwers with all the formalities of a criminal court.

We have heard it obſerved, that to attend a courſe of ſuch lectures would be of the utmoſt advantage to all who may be called upon to ſerve as jurymen in criminal trials; but of the truth of this obſervation we are more than doubtful. Perſons who are only *half* inſtructed are always conceited of their own attainments; and men not acquainted with anatomy and phyſiology cannot be *more* than half inſtructed by the ableſt courſe poſſible to be given of medical juriſprudence. Such perſons indeed can hardly avoid miſtaking the ſenſe of the profeſſor's language, however perſpicuous that language may be. Of this we had lately a very ſtriking inſtance. A gentleman, by no means illiterate, though a ſtranger to anatomical and phyſiological ſcience, was expatiating to the writer of this article upon the general importance of medical juriſprudence, a courſe of which, he ſaid, he had attended for the ſole purpoſe of qualifying himſelf for diſcharging the important duties of a juryman. Upon being aſked what he had learned? he replied, that he had been taught, among other things which we thought frivolous, to diſcern, from the ſymptoms of *hanging*, whether the dead man had been hanged by *himſelf* or by *another*. We need not ſurely obſerve, that no ſuch leſſon was ever taught in any univerſity, or by any medical lecturer; but it is worthy of conſideration, whether lectures on medical juriſprudence may not have the moſt pernicious effects on the minds of men ſo little qualified as this gentleman to profit by them. To the regularly educated phyſician and ſurgeon ſuch lectures may prove uſeful; to the plain citizen, not ſkilled in anatomy and phyſiology, they muſt prove dangerous; as their only tendency is to make him deſpiſe the evidence given before him by the regular phyſician or ſurgeon; to place implicit confidence in his own ſuperficial knowledge; and thus to decide at random on the life or death of his fellow creature:

> A little learning is a dangerous thing;
> Drink deep, or taſte not the Pierian ſpring.

MEDINA, the capital of the kingdom of Woolli in Africa, is ſituated in 13° 40′ N. Lat. and 12° 40′ W. Long. It is a place of conſiderable extent, and may contain from 800 to 1000 houſes. It is fortified in the

common

Medusa. Megameter.

common African manner, by a surrounding high wall built of clay, and an outward fence of pointed stakes and prickly bushes; but the walls are neglected, and the outward fence has suffered considerably from the active hands of busy housewives, who pluck up the stakes for firewood. Mr Park passed through it on his route eastward, and was treated with much kindness both by the king and the people. The good old sovereign warned him of the dangers he was about to encounter, and endeavoured to persuade him to relinquish all thoughts of his journey eastward; but when he could not prevail, he gave him a guide, who conducted him in safety to Koojar, the frontier town of the kingdom towards Bondou, from which it is separated by an intervening wilderness of two days journey. Here our author was presented, by way of refreshment, with a liquor which tasted so much like the strong beer of his native country (and very good beer too), as to induce him to inquire into its composition; and he learned, with some degree of surprise, that it was actually made from corn which had been previously malted, much in the same manner as barley is malted in Great Britain: a root yielding a grateful bitter was used in lieu of hops, the name of which he forgot; but the corn which yields the wort is the *holcus spicatus* of botanists.

MEDUSA. In addition to the different species of this genus of vermes described in the *Encyclopædia*, that which is represented in two different attitudes, fig. 1. and 2. and which strongly resembles a bagpipe in shape, may be worthy of notice. It is merely a white transparent vesicle, furnished with several blue tentacles yellowish at their extremity; its long tail, which is also blue, appears to be composed of a number of small glandulous grains, flattened and united together by a gelatinous membrane. The upper part of the vesicle exhibits a kind of seam with alternate punctures of three different sizes; its elongated part, which may be considered as the head of the animal, is terminated by a single trunk, the exterior edge of which is fringed with 25 or 26 tentacles, much smaller than those which originate from the insertion of its long tail, and the number of which sometimes amounts to 30. By means of these last, the diameter of which it is capable of increasing at pleasure by forcing in a little of the air from its body, it fixed itself to the side of the vessel, in which it was placed, in such a manner as that the extremity of some of its tentacles occupied a surface of two or three lines from its body. The most moveable part of the vesicle is its elongation, or the head of the animal, as it is by means of this that it performs its different motions. The rounded substance, marked by the letter P, is situated in the centre of the larger tentacles, which are firmly fixed to the body of the animal near its tail; and is only an assemblage of a few minute gelatinous globules, from the middle of which arise other larger globules, with a small peduncle, about the middle of which is fixed a curved bluish coloured body, which is represented magnified in two positions at R. Martiniere, the naturalist, who accompanied Perouse in his voyage round the world, met with this animal in about the 20th degree of lat. and 179° of long. east from Paris.

Plate XXXVI.

MEGAMETER, a name sometimes given to the MICROMETER, which see, *Encycl.*

Mehal. Meninski.

MEHALL, in the language of Bengal, a place or district.

MENINSKI (Franciscus), a most celebrated German orientalist, was born in Lorraine, then subject to the emperor, in the year 1623; and for copiousness of learning, elegance of genius, and profound knowledge of languages, particularly those of the East, proved undoubtedly one of the principal ornaments of the age in which he lived. He studied at Rome under Giattino. When he was about 30, his love of letters induced him to accompany the Polish ambassador to Constantinople, where he studied the Turkish language under Bobovius and Ahmed, two very skilful teachers. So successful was he in this study, that when he had been there only two years, the place of first interpreter to the Polish embassy at the Porte was promised to him. When the place became vacant, he was accordingly appointed to it, and obtained so much credit by his conduct, that, after a time, he was sent for into Poland, and again sent out with full powers as ambassador to the Porte. For his able execution of this office, he was further honoured, by being naturalized in Poland; on which occasion he added the Polish termination of *ski* to his family name, which was Menin. Being desirous afterwards to extend his sphere of action, he went to the court of the emperor as interpreter of oriental languages in 1661. Here also, as in other instances, his talents and behaviour obtained the highest approbation; on which account he was not only sent as interpreter to several imperial ambassadors at the Porte, but was intrusted in many important and confidential services; and, in 1669, having paid a visit to the holy sepulchre at Jerusalem, was made one of the knights of that order. After his return to Vienna he was advanced to further honours; being made one of the counsellors of war to the emperor, and first interpreter of oriental languages. At Vienna he died at the age of 75, in the year 1698. His great work, 1. The "Thesaurus linguarum orientalium," was published at Vienna in 1680, in 4 vols folio; to which was added, in 1687, another volume, intitled, "Complementum Thesauri linguarum orientalium, seu onomasticum Latino-Turcico-Arabico Persicum." The former volumes having become extremely scarce, partly on account of the destruction of a great part of the impression, in the siege of Vienna by the Turks in 1683, a design was formed some time ago in England of reprinting the work, by a society of learned men, among whom was Sir William Jones. But as this undertaking, probably on account of the vast expence which must have been incurred, did not proceed, the empress queen Maria Theresa, who had heard of the plan, took it upon herself, and with vast liberality furnished every thing necessary for its completion. In consequence of this, it was begun to be splendidly republished at Vienna in 1780, with this title: "Francisci a Mesgnien Meninski Lexicon Arabico-Persico-Turcicum, adjecta ad singulas voces et Phrases interpretatione Latina, ad usitatiores, etiam Italica." Of this edition only two vols folio are yet published, extending no farther than *zal*, the ninth letter of the Arabic alphabet, which is about a third of the whole. The delay of the rest is much to be lamented. In this edition, say the editors, the Lexicon of Meninski may be said to be increased, diminished, and amended. *Increased*, because many Arabic and Persian

words

Meninſki, Merchetta. words are added, from Wankuli and Ferhengi, the beſt Arabic and Perſic lexicographers whom the Eaſt has produced; and from Herbelot are inſerted the names of kingdoms, cities, and rivers, as well as phraſes in common uſe among the Turks, &c. *Diminiſhed*, becauſe many uſeleſs ſynonyma are omitted, which rather puzzled than aſſiſted the ſtudent; as well as all the French, Poliſh, and German interpretations, the Latin being conſidered as ſufficient for all men of learning. *Amended*, with reſpect to innumerable typographical errors; which, however, from a work of this nature, no care can perhaps altogether exclude. The other works of Meninſki were occaſioned chiefly by a violent conteſt between him and a man named J. B. Podeſta, in which much acrimony was employed on both ſides. Theſe it is hardly worth while to enumerate, but they may all be ſeen in the account of his life from which this article is taken (A). It ſhould be obſerved, however, that in 1671, Podeſta publiſhed a book, intitled, "Prodromus novi linguarum orientalium collegii, juſſu Aug. &c. erigendi, in Univ. Viennenſi;" to which Meninſki oppoſed, 2. "Meninſkii Antidotum in Prodromum novi ling. orient. collegii, &c." 4to. But ſuch was the credit of his antagoniſt in the univerſity, that ſoon after there came out a decree in the name of the rector and conſiſtory, in which that antidote of Meninſki's is proſcribed and prohibited, for ſix ſpecific reaſons, as impious and infamous. Meninſki was defended againſt this formidable attack by a friend, in a ſmall tract, intitled, "Veritas defenſa, ſeu juſtitia cauſæ Dn. F. de M. M [Meninſki] contra infame decretum Univerſitatis Viennenſis, Anno 1674, 23 Novembris, &c. ab Amico luci expoſita, Anno 1675," in which this friend expoſes, article by article, the falſehood of the decree, and exclaims ſtrongly againſt the arts of Podeſta. This tract is in the Britiſh Muſeum. Podeſta was oriental ſecretary to the emperor, and profeſſor of thoſe languages at Vienna; but is deſcribed in a very ſatirical manner by the defender of Meninſki. "Podeſta, natura Semi Italus, ſtatura nanus, cæcutiens, balbus, imo bardus repertus, aliiſque vitiis ac ſtultitiis plenus, adeoque ad diſcendas linguas orientales inhabilis." A liſt of the works of Podeſta is, however, given by the late editors of Meninſki.

MERCHETTA, or *Marchetta Mulierum*, is commonly ſuppoſed to have been a right which, during the prevalence of the feudal ſyſtem, the lord had of paſſing the firſt night after marriage with his female villain. This opinion has been held by the greater part of our antiquarians; and we have adopted it in our hiſtory of SCOTLAND publiſhed in the *Encyclopædia*. It appears, however, to be a miſtake. That there was a cuſtom called *merchetta mulierum*, which prevailed not only in England, Scotland, Wales, and the iſle of Guernſey, but alſo on the continent, is indeed a fact unqueſtionable; but Mr Aſtle has clearly proved, that, inſtead of *Archæologia, vol. xii.* being an adulterous connection, the *merchetta* was a compact between the lord and his vaſſal for the redemption of an *offence* committed by that vaſſal's *unmarried* daughter. He admits, however, that it denoted likewiſe a fine paid by a *ſokeman* or a *villan* to his lord, for a licence to marry his daughter to a free man; and that if the vaſſal gave her away without obtaining ſuch a licence, he was liable to pay a heavier fine. He quotes two authorities in ſupport of his opinion from Bracton; one of which we ſhall tranſcribe, as being alone complete evidence.

"Ric. Burre tenet unum meſuagium et debet telliagium ſectam curiæ, et *merchet*, hoc modo, *quod ſi maritare voluerit filiam ſuam cum quodam libero homine, extra villam, faciet pacem domini pro maritagio, et ſi eam maritaverit alicui cuſtumario villæ, nihil debuit pro maritagio.*"

"The probable reaſon of the cuſtom (ſays Mr Aſtle) appears to have been this. Perſons of low rank, reſiding on an eſtate, were either *aſcripti glebæ*, or were ſubjected to ſome ſpecies of ſervitude ſimilar to the *aſcripti glebæ*. They were bound to reſide on the eſtate, and to perform ſeveral ſervices to the lord. As women neceſſarily followed the reſidence of their huſbands, the conſequence was, that when a woman of low rank married a ſtranger, the lord was deprived of part of his live ſtock; he therefore required a fine to indemnify him for the loſs of his property." Further particulars on the *merchetta* are to be found in the Appendix to vol. 1ſt of *Sir David Dalrymple's Annals of Scotland*.

Meridian, Meſolabe. MERIDIAN LINE, an arch, or part of the meridian of the place, terminated each way by the horizon. Or, a meridian line is the interſection of the plane of the meridian of the place with the plane of the horizon, often called a north-and-ſouth line, becauſe its direction is from north to ſouth.

In the article ASTRONOMY (*Encycl.*), nº 376 and 377, we have given two methods of drawing a meridian line; but it may be proper to add, in this place, the following improvement of the former of theſe from Dr Hutton's Mathematical Dictionary. "As it is not eaſy (ſays the Doctor) to determine preciſely the extremity of the ſhadow, it will be beſt to make the ſtile flat at the top, and to drill a ſmall hole through it, noting the lucid point projected by it on the ſeveral concentric circles, inſtead of marking the extremity of the ſhadow itſelf on theſe circles."

We ſhall give another method of drawing a meridian line from the ſame valuable dictionary.

"Knowing the ſouth quarter pretty nearly, obſerve the altitude FE of ſome ſtar on the eaſt ſide of it, and Plate XXXV. not far from the meridian HZRN: then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, direct it to the weſtern ſide of the meridian, and wait till you find the ſtar has the ſame altitude as before, as *fe*. Laſtly, biſect the angle EC*e*, formed by the interſection of the two planes in which the quadrant has been placed at the time of the two obſervations, by the right line HR, which will be the meridian ſought."

Magnetical MERIDIAN, is a great circle paſſing thro' or by the magnetical poles; to which meridians the magnetical needle conforms itſelf. See MAGNETISM, *Suppl.*

MESOLABE, or MESOLABIUM, a mathematical inſtrument invented by the ancients, for finding two mean

(A) We have taken this article from the Biographical Dictionary; the editors of which took it from the life of Meninſki prefixed to the new edition of his great work.

mean proportionals mechanically, which they could not perform geometrically. It consists of three parallelograms, moving in a groove to certain intersections. Its figure is described by Eutocius, in his Commentary on Archimedes. See also Pappus, lib. 3.

MESO-LOGARITHM, a term used by Kepler to signify the logarithms of the cosines and cotangents.

MESURATA, a seaport of the kingdom of Tripoli, in Africa. A caravan proceeds from this place to Fezzan, and other interior parts toward the south of Africa. It is 260 miles north of Mourzook. E. lon. 15. 5. N. lat. 31. 3.

METALLIC TRACTORS. See PERKINISM in this *Suppl.*

METONIC CYCLE, called also the *Golden Number*, and *Lunar Cycle*, or *Cycle of the Moon*, that which was invented by Meton the Athenian; being a period of 19 years. See CYCLE, *Encycl.*

MHA RAJAH, the highest title of Hindoos.

MICROCOUSTICS, or MICROPHONES, instruments contrived to magnify small sounds, as microscopes do small objects.

MICROCOSMIC SALT. See CHEMISTRY-*Index*, *Suppl.*

MIDDLE LATITUDE, is half the sum of two given latitudes; or the arithmetical mean, or the middle between two parallels of latitude. Therefore,

If the latitudes be of the same name, either both north or both south, add the one number to the other, and divide the sum by 2; the quotient is the middle latitude, which is of the same name with the two given latitudes. But

If the latitudes be of different names, the one north and the other south; subtract the less from the greater, and divide the remainder by 2, so shall the quotient be the middle latitude, of the same name with the greater of the two.

MIDSUMMER-DAY, is held on the 24th of June, the same day as the nativity of St John the Baptist is held.

MILK, or MILKYET, property in Bengal.

MILLS of various kinds are described in the article MECHANICS (*Encycl.*); and he who shall study that article, together with *Water-Works*, and MACHINERY, in this *Supplement*, will have a sufficient knowledge of the principles upon which mills must be constructed so as that they may produce their proper effects. The subject is introduced into this place merely to put it into the power of our countrymen to adopt, if they shall think fit, the improvements which have been made in the machinery of flour mills in America.

The chief of these consist in a new application of the screw, and the introduction of what are called elevators, the idea of which was evidently borrowed from the chain pump. The screw is made by sticking small thin pieces of board, about three inches long and two wide, into a cylinder, so as to form the spiral line. This screw is placed in a horizontal position, and by turning on its axis it forces wheat or flour from one end of a trough to the other. For instance, in the trough which receives the meal immediately coming from the stones, a screw of this kind is placed, by which the meal is forced on, to the distance of six or eight feet, perhaps, into a reservoir; from thence, without any manual labour, it is conveyed to the very top of the mill by the elevators, which consist of a number of small buckets of the size of tea cups, attached to a long band that goes round a wheel at the top, and another at the bottom of the mill. As the band revolves round the wheels, these buckets dip into the reservoir of wheat or flour below, and take their loads up to the top, where they empty themselves as they turn round the upper wheel. The elevators are inclosed in square wooden tubes, to prevent them from catching in any thing, and also to prevent dust. By means of these two simple contrivances no manual labour is required from the moment the wheat is taken to the mill till it is converted into flour, and ready to be packed, during the various processes of screening, grinding, sifting, &c.

That this is a considerable improvement is obvious; and we are not without hopes that it may be adopted. The licentiousness of an English mob has indeed persecuted an Arkwright, expelled the inventor of the fly-shuttle from his native country, and by such conduct prevented the re-erection of the Albion mills, and the general establishment of saw-mills through the kingdom; but their sovereignty perhaps will not be roused by so easy and simple a contrivance as this to lessen the quantity of manual labour. For an account of the Dutch oil-mill, which was somehow omitted in its proper place in the *Encyclopædia*, see OIL-MILL in this *Supplement*.

MINERALOGY

Definition. IS a science, the object of which is the description and arrangement of *inorganic bodies* or *minerals*; or of *all* the bodies which belong to our globe, excepting *animal* and *vegetable substances*.

Since the publication of the article MINERALOGY, *Encycl.* scarcely a single day has passed without the discovery of some new mineralogical fact, or the detection of some old and unsuspected error. These improvements cannot be overlooked in the present *Supplement*. But they are so numerous in every part of the science, that we can hardly notice them without giving a pretty complete view of the present state of mineralogy. This will scarcely occupy more room, and must be much more useful as well as entertaining, than an undigested mass of annotations and remarks. We undertake this task the more readily, because in the article MINERALOGY in the *Encyclopædia*, the improvements of Mr Werner and his disciples, to which the science is indebted for a great part of its present accuracy, have been entirely overlooked.

The object of mineralogy is twofold. 1. To *describe* every mineral with so much accuracy and precision, that it may be easily distinguished from every other mineral; 2. To *arrange* them into a system in such a manner that every mineral may be easily referred to its proper place, and that a person may be able, merely by the help of the system, to discover the *name* of any mineral whatever. When these two objects are accomplished, mineralogy, Object.

neralogy, strictly so called, is completed. But were we to stop here, the utility of the science, if it would be entitled to the name of science, could hardly be considered as very great. We must therefore apply *chemistry* to discover the ingredients of which minerals are composed, and to detect, if possible, the laws which these ingredients have observed in their combination. Thus we shall really extend our knowledge of inorganic nature, and be enabled to apply that knowledge to the improvement of almost every art and manufacture.

3 Division of the article.

Mineralogy naturally divides itself into three parts. The *first* treats of the method of describing minerals; the *second*, of the method of arranging them; and the *third* exhibits them in a system described and arranged according to the rules laid down in the two first parts. These three parts shall be the subjects of the following chapters; and we shall finish the article with a chapter on the chemical analysis of minerals.

Chap. I. Of the Description of Minerals.

Nothing, at first sight, appears easier than to describe a mineral, and yet, in reality, it is attended with a great deal of difficulty. The mineralogical descriptions of the ancients are so loose and inaccurate, that many of the minerals to which they allude cannot be ascertained; and consequently their observations, however valuable in themselves, are often, as far as respects us, altogether lost. It it obvious, that to distinguish a mineral from every other, we must either mention some peculiar property, or a collection of properties, which exist together in no other mineral. These properties must be described in terms rigidly accurate, which convey precise ideas of the very properties intended, and of no other properties. The smallest deviation from this would lead to confusion and uncertainty. Now it is impossible to describe minerals in this manner, unless there be a peculiar term for each of their properties; and unless this term be completely understood. Mineralogy therefore must have a language of its own; that is to say, it must have a *term* to denote every mineralogical property, and each of these terms must be accurately defined. The language of mineralogy was invented by the celebrated Werner of Freyberg, and first made known to the world by the publication of his treatise on *the external characters of minerals*. Of this language we shall give a view in the following general description of the properties of minerals (A).

4 Properties of minerals.

The properties of minerals may be divided into two classes. *1st*, Properties discoverable without destroying the texture of the mineral; *2d*, Properties resulting from the action of other bodies on it. The first class has, by Werner and his disciples, been called *external* properties, and by some French writers *physical*; the second class has been called *chemical*.

The *external* properties may be arranged under the following heads:

External Characters.

1 Figure.	8 Ductility.	14 Sound.
2 Surface.	9 Fracture.	15 Smell.
3 Transparency.	10 Texture.	16 Taste.
4 Colour.	11 Structure.	17 Gravity.
5 Scratch.	12 Fragments.	18 Magnetism.
6 Lustre.	13 Feel.	19 Electricity.
7 Hardness.		

I. By FIGURE is meant the shape or form which a mineral is observed to have. The *figure* of minerals is either *regular*, *particular*, or *amorphous*. 1. Minerals which assume a regular figure are said to be crystallized*. The *sides* of a crystal are called *faces*; the sharp line formed by the inclination of two faces is called an *edge*; and the corner, or angle, formed by the meeting of several edges in one point, is called a *solid angle*, or simply *an angle*. Thus a cube has six faces, twelve edges, and eight angles. 2. Some minerals, though not crystallized, affect a *particular* figure. These particular figures are the following: *Globular*, like a globe; *oval*, like an oblong spheriod; *ovate*, like an egg; *cheese-shaped*, a very flattened sphere; *almond-shaped*, like an almond; *centicular*, like a double convex lense, compressed and gradually thinner towards the edges; *cuneiform*, like a wedge; *nodulous*, having depressions and protuberances like a potatoe; *botryoidal*, like grapes closely pressed together; *dentiform*, longish and tortuous, and thicker at the bottom than the top; *wireform*, like a wire; *capillary*, like hair, finer than the preceding; *retiform*, threads interwoven like a net; *dendritic*, like a tree, having branches issuing from a common stem; *shrubform*, branches not arising from a common stem; *coraloidal*, branched like coral; *stalactitical*, like isicles; *clavated*, like a club, long, and thicker at one end than another; *fasciform*, long straight cylindrical bodies, united like a bundle of rods; *tubular*, cylindrical and hollow. 3. When minerals have neither a regular nor particular shape, they are said to be *amorphous*. 5

5 Figure.

* See Chemistry, Part II. Chap. iv. Sup.

6 Surface.

II. By SURFACE is meant the appearance of the external surface of minerals. The *surface* is either *uneven*, composed of small unequal elevations and depressions; *scabrous*, having very small *sharp* and rough elevations, more easily felt than seen; *drusy*, covered with very minute crystals; *rough*, composed of very minute *blunt* elevations, easily distinguishable by the feel; *scaly*, composed of very minute thin scale-like leaves; *smooth*, free from all inequality or roughness; *specular*, having a smooth polished surface like a mirror; or *streaked*, having elevated, straight, and parallel lines. This last character is confined to the *surface* of crystals. The *streaks* are either *transverse*; *longitudinal*; *alternate*, in different directions on different faces; *plumose*, running from a middle rib; or *decussated*, crossing each other.

7 Transparency.

III. By TRANSPARENCY is meant the proportion of light which minerals are capable of transmitting. They are *transparent* or *pellucid*, when objects can be seen distinctly through them; *diaphanous*, when objects are seen

(A) The fullest account of Werner's external characters which we have seen in the English language, has been given by Dr Townson in his *Philosophy of Mineralogy*. We have availed ourselves of this book, in order to exhibit some of the latest improvements of Werner and his disciples. The reader may also consult *Werner's Treatise*, published at Leipsic in 1774; or the *French translation* published at Dijon in 1790. See also *Rome de Lisle. Des caracters exterieur des mineraux*. And *Hauy Jour. d'hist. Nat.* II. 56.

External Characters seen through them indistinctly; *subdiaphanous*, when light passes but in so small a quantity that objects cannot be seen through them (B); *opaque*, when no light is transmitted.

When opaque minerals become transparent in water, they are called *hydrophanous*. When objects are seen double through a transparent mineral, it is said to *refract doubly*.

Colour. IV. The colours of minerals may be reduced to eight classes.

1. *Whites.*

Snow white. Pure white.

Reddish white. White with a light tint of red.

Yellowish white. White with a light tint of yellow.

Silver white. Yellowish white with a metallic lustre.

Greyish white. White with a light tint of black.

Greenish white. White with a light tint of green.

Milk white. White with a light tint of blue.

Tin white. Milk white of a metallic lustre.

2. *Greys.*

Bluish grey. Grey with a little blue.

Lead grey. Bluish grey with a metallic lustre.

Pearl grey. Light grey with a slight mixture of violet blue.

Smoke grey. Dark grey with a little blue and brown.

Greenish grey. Light grey tinged with green.

Yellowish grey. A light grey tinged with yellow.

Steel grey. A dark grey with a light tint of yellow and a metallic lustre.

Black grey. The darkest grey with a tint of yellow.

3. *Blacks.*

Greyish black. Black with a little white.

Brownish black. Black with a tint of brown.

Black. Pure black.

Iron black. Pure black with a small mixture of white and a metallic lustre.

Bluish black. Black with a tint of blue.

4. *Blues.*

Indigo blue. A dark blackish blue.

Prussian blue. The purest blue.

Azure blue. A bright blue with scarce a tint of red.

Smalt blue. A light blue.

Violet blue. A mixture of azure blue and carmine.

Lavender blue. Violet blue mixed with grey.

Sky blue. A light blue with a slight tint of green.

5. *Greens.*

Verdigris green. A bright green of a bluish cast.

Seagreen. A very light green, a mixture of verdigris green and grey.

Beryl green. The preceding, but of a yellowish cast.

Emerald green. Pure green.

Grass green. Pure green with a tint of yellow.

Apple green. A light green formed of verdigris green and white.

Leek green. A very dark green with a cast of brown.

Blackish green. The darkest green, a mixture of leek green and black.

Pistachio green. Grass green, yellow and a little brown.

Olive green. A pale yellowish green with a tint of brown.

Asparagus green. The lightest green, yellowish with a little brown and grey.

6. *Yellows.*

Sulphur yellow. A light greenish yellow.

Brass yellow. The preceding, with a little less green and a metallic lustre.

Lemon yellow. Pure yellow.

Gold yellow. The preceding with a metallic lustre.

Honey yellow. A deep yellow with a little reddish brown.

Wax yellow. The preceding, but deeper.

Pyritaceous. A pale yellow with grey.

Straw yellow. A pale yellow, a mixture of sulphur yellow and reddish grey.

Wine yellow. A pale yellow with a tint of red.

Ochre yellow. Darker than the preceding, a mixture of lemon yellow with a little brown.

Isabella yellow. A pale brownish yellow, a mixture of pale orange with reddish brown.

Orange yellow. A bright reddish yellow, formed of lemon yellow and red.

7. *Reds.*

Aurora red. A bright yellow red, a mixture of scarlet and lemon yellow.

Hyacinth red. A high red like the preceding, but with a shade of brown.

Brick red. Lighter than the preceding; a mixture of aurora red and a little brown.

Scarlet red. A bright and high red with scarce a tint of yellow.

Copper red. A light yellowish red with the metallic lustre.

Blood red. A deep red, a mixture of crimson and scarlet.

Carmine red. Pure red verging towards a cast of blue.

Cochineal red. A deep red; a mixture of carmine with a little blue and a very little grey.

Crimson red. A deep red with a tint of blue.

Flesh red. A very pale red of the crimson kind.

Rose red. A pale red of the cochineal kind.

Peach blossom red. A very pale whitish red of the crimson kind.

Mordoré. A dark dirty crimson red; a mixture of crimson and a little brown.

Brownish red. A mixture of blood red and brown.

8. *Browns.*

Reddish brown. A deep brown inclining to red.

Clove brown. A deep brown with a tint of carmine.

Yellowish brown. A light brown verging towards ochre yellow.

Umber brown. A light brown, a mixture of yellowish brown and grey.

Hair brown. Intermediate between yellow brown and clove brown with a tint of grey.

Tombac brown. A light yellowish brown, of a metallic lustre, formed of gold yellow and reddish brown

Bb 2 Liver

(B) After Mr Kirwan, we have denoted these three degrees of transparency by the figures 4, 3, 2. When a mineral is subdiaphanous only at the edges, that is denoted by the figure 1. Opacity is sometimes denoted by 0.

Liver brown. A dark brown; blackiſh brown with a tint of green.

Blackiſh brown. The darkeſt brown.

Colours, in reſpect of intenſity, are either *dark*, *deep*, *light*, or *pale*. When a colour cannot be referred to any of the preceding, but is a mixture of two, this is expreſſed, by ſaying, that the prevailing one *verges* towards the other, if it has only a ſmall tint of it; *paſſes* into it, if it has a greater.

V. By the SCRATCH OR STREAK, is meant the mark left when a mineral is ſcratched by any hard body, as the point of a knife. It is either *ſimilar*, of the ſame colour with the mineral; or *diſſimilar*, of a different colour.

10 uſtre

VI LUSTRE, is the gloſs or brightneſs which appears on the external ſurface of a mineral, or on its internal ſurface when freſh broken. The firſt is called *external*, the ſecond *internal* luſtre. Luſtre is either *common*, that which moſt minerals poſſeſs; *ſilky*, like that of ſilk or mother of-pearl; *waxy*, like that of wax; *greaſy*, like that of greaſe; or *metallic*, like that of metals.

As to the degree, the greateſt is called *ſplendent*, the next *ſhining*, the third *dulliſh*; and when only a few ſcattered particles ſhine, the luſtre is called *dull* (c).

11 Hardneſ

VII. We have uſed figures to denote the comparative HARDNESS of bodies; for an explanation of which, we refer to the article CHEMISTRY, Vol. I. p. 224. of this *Supplement*.

12 Ductility and brittleneſs.

VIII. With reſpect to DUCTILITY and BRITTLENESS, minerals are either *malleable*; *ſectile*, capable of being cut without breaking, but not malleable; *flexile*, capable of being bent, and when bent retaining their ſhape; or *elaſtic*, capable of being bent, but recovering their former ſhape Minerals deſtitute of theſe properties are *brittle*. Brittle minerals, with reſpect to the eaſe with which they may be broken, are either *very tough*, *tough*, *fragile*, or *very fragile*.

13 Fracture.

IX. By FRACTURE is meant the freſh ſurface which a mineral diſplays when broken. It is either *flat*, without any general elevation or depreſſion; or *conchoidal*, having wide extended roundiſh hollows and gentle riſings. When theſe are not *very* evident, the fracture is called *flat* conchoidal; when they are ſmall, it is called *ſmall* conchoidal; and when of great extent, *great* conchoidal.

The fracture may alſo be *even*, free from all aſperities; *uneven*, having many ſmall, ſharp, abrupt, irregular elevations and inequalities; and from the ſize of theſe, this fracture is denominated *coarſe*, *ſmall*, or *fine*; *ſplintery*, having ſmall, thin, half detached, ſharp edged ſplinters, according to the ſize of which this fracture is denominated *coarſe* or *fine*; or *rugged*, having many very minute ſharp hooks, more ſenſible to the hand than the eye.

14 Texture.

X. By TEXTURE is meant the internal ſtructure or diſpoſition of the matter of which a mineral is compoſed, which may be diſcovered by breaking it. The texture is either *compact*, without any diſtinguiſhable parts, or the appearance of being compoſed of ſmaller parts; *earthy*, compoſed of very minute *almoſt* imperceptible rough parts; *granular*, compoſed of ſmall ſhapeleſs grains; *globuliform*, compoſed of ſmall ſpherical bodies; *fibrous*, compoſed of fibres which may be *long*, *ſhort*, *ſtraight*, *crooked*, *parallel*, *divergent*, *ſtellated*, *faſciculated*, or *decuſſated*; *radiated*, conſiſting of long narrow flattiſh lamellæ; or *lamellar* or *foliated*, conſiſting of ſmooth continued plates covering each other: theſe plates may be either *ſtraight*, *crooked*, or *undulating*. Extern Charact

XI. The STRUCTURE OR COMPOUND TEXTURE is the manner in which the parts that form the texture are diſpoſed. It is either *ſlaty*, in ſtraight layers like ſlate; *teſtaceous*, in incurvated layers; *concentric*, in concentric layers; or *columnar*, in columns. 15 Structu

The *texture* and *ſtructure* may at firſt view appear the ſame; but in reality they are very different. Thus common ſlate has often the *ſlaty ſtructure* and *earthy texture*. The texture of pitcoal is compact, but its ſtructure is often ſlaty.

XII. By FRAGMENTS is meant the ſhape of the pieces into which a mineral breaks when ſtruck with a hammer. They are either *cubic*; *rhomboidal*; *wedgeſhaped*; *ſplintery*, thin, long, and pointed; *tabular*, thin, and broad, and ſharp at the corners, as common ſlate; or *indeterminate*, without any particular reſemblance to any other body. The *edges* of indeterminate fragments are either *very ſharp*, *ſharp*, *ſharpiſh*, or *blunt*. 16 Fragme

XIII. By the FEEL of minerals is meant the ſenſation which their ſurfaces communicate when handled. The feel of ſome minerals is *greaſy*, of others *dry*, &c. 17 Feel.

XIV. Some minerals when ſtruck give a *clear* SOUND, as common ſlate; others a *dull* ſound. 18 Sound

The SMELL, TASTE, SPECIFIC GRAVITY, and MAGNETISM of minerals, require no explanation.

With reſpect to ELECTRICITY, ſome minerals become electric when *heated*, others when *rubbed*, others cannot be rendered electric. The electricity of ſome minerals is *poſitive* or *vitreous*, of others *negative* or *reſinous*.

As for the CHEMICAL properties of minerals, they have been already explained in the article CHEMISTRY, which makes a part of this *Supplement*. And for the deſcription of the blow-pipe, and the manner of uſing it, we refer the reader to a treatiſe on that ſubject prefixed to the article MINERALOGY in the *Encyclopædia*.

CHAP. II. OF THE ARRANGEMENT OF MINERALS.

MINERALS may be arranged two ways, according to their external characters, and according to their chemical compoſition. The firſt of theſe methods has been called an *artificial* claſſification; the ſecond, a *natural* one. The firſt is indiſpenſably neceſſary for the ſtudent of nature; the ſecond is no leſs indiſpenſable for the proficient who means to turn his knowledge to account. Without the firſt, it is impoſſible to diſcover the *names* of minerals; and without the ſecond, we muſt remain ignorant of their uſe.

Almoſt every ſyſtem of mineralogy hitherto publiſhed, at leaſt ſince the appearance of Werner's *external characters*, has attempted to combine theſe two arrangements, and to obtain at one and the ſame time the advantages peculiar to each. But no attempt of this kind has hitherto ſucceeded. Whether this be owing to any thing impoſſible in the undertaking, or to the preſent

(c) Theſe four degrees have been denoted by Kirwan by the figures 4, 3, 2, 1, and no luſtre by 0. We have imitated him in the preſent article.

Artificial System. present imperfect state of mineralogy, as is more probable, we do not take upon us to determine. But surely the want of success which has hitherto attended all attempts to combine the two arrangements, ought to suggest the propriety of separating them. By adhering strictly to one language, the trouble of studying two different systems would be entirely prevented. They would throw mutual light upon each other: the artificial system would enable the student to discover the *names* of minerals; the natural would enable him to arrange them, and to study their properties and uses.

The happy arrangement of Cronstedt, together with the subsequent improvements of Bergman, Werner, Kirwan, Hauy, and other celebrated mineralogists, has brought the *natural* system of mineralogy to a considerable degree of perfection. But an *artificial* system is still a desideratum; for excepting Linnæus, whose success was precluded by the state of the science, no one has hitherto attempted it. Though we are very far from thinking ourselves sufficiently qualified for undertaking such a task, we shall nevertheless venture, in the next chapter, to sketch out the rudiments of an artificial system. The attempt, at least, will be laudable, even though we should fail.

Chap. III. Artificial System.

19 Artificial classes. Minerals may be divided into six classes:

1. Minerals that cannot be fused by the blow-pipe *per se*.
2. Minerals fusible *per se* by the blow-pipe.
3. Minerals fusible by the blow-pipe *per se* when exposed to the blue flame, but not when exposed to the yellow flame.
4. Minerals fusible *per se* by the blow-pipe; and when in fusion, partly evaporating in a visible smoke.
5. Minerals which totally evaporate before the blow-pipe.
6. Minerals totally soluble in muriatic acid with effervescence, the solution colourless.

Under these heads we shall arrange the subjects of the mineral kingdom.

Class I. INFUSIBLE.

ORDER I. Specific gravity from 16 to 12.
Genus I. Colour whitish iron grey.
Species 1. Native platinum.

ORDER II. Sp. gr. 8.5844 to 7.006.
Genus I. Attracted by the magnet.
Sp. 1. Native iron.
Genus II. Not attracted by the magnet.
Sp. 1. Native copper.
Flexible and malleable. Colour usually red.
Wolfram.
Brittle. Colour usually brown or black.

ORDER III. Sp. gr. from 6.4509 to 5.8.
Genus I. Forms a blue glass with microcosmic salt, which becomes colourless in the yellow, but recovers its colour in the blue flame.
Sp. 1. Tungstat of lime.
Genus II. Forms with microcosmic salt a permanently coloured bead.
Sp. 1. Sulphuret of cobalt.

ORDER IV. Sp. gr. from 4.8 to 4.5.
Genus I. Tinges borax dark green.
Sp. 1. Common magnetic iron stone.
Genus II. Tinges borax reddish brown.
Sp. 1. Grey ore of manganese.

ORDER V. Sp. gr. from 4.4165 to 3.292. Infusible with fixed alkalies.
Genus I. Hardness 20.
Sp. 1. Diamond.
Genus II. Hardness 15 to 17. Causes single refraction.
Sp. 1. Telesia.
Sp. 2. Corundum.
Genus III. Hardness 13. Single refraction.
Sp. 1. Ruby.
Crystallizes in octohedrons.
Genus IV. Hardness 12. Single refraction.
Sp. 1. Chrysoberyl.
Genus V. Hardness 12. Causes double refraction. Becomes electric when heated.
Sp. 1. Topaz.
Genus VI. Hardness 10 to 16. Double refraction. Sp. gr. 4.2 to 4.165.
Sp. 1. Zircon.
Genus VII. Hardness 6 to 9. Feels greasy.
Sp. 1. Cyanite.
Genus VIII. Hardness 9 to 10. Feel not greasy. Double refraction. Sp. gr. 3.283 to 3.285.
Sp. 1. Chrysolite.
Genus IX. Hardness 12. Infusible with borax. Colour of large masses black, of thin pieces deep green.
Sp. Ceylanite.
(*Phosphat of lime.*)

ORDER VI. Sp. gr. from 2.9829 to 1.987. Infusible with fixed alkalies.
Genus I. Hardness 12.
Sp. 1. Emerald.
Genus II. Hardness 10.
Sp. 1. Jade.
Genus III. Hardness 6 to 7. Somewhat transparent.
Sp. 1. Phosphat of lime.
Before the blow-pipe becomes surrounded with a luminous green vapour.
Genus IV. Hardness 6. Opaque.
Sp. 1. Micarelle.
Genus V. Stains the fingers. Colour lead grey.
Sp. 1. Plumbago.
Spanish wax rubbed with plumbago does not become electric; or if it does, the electricity is negative. Streak lead grey even on earthen ware.

ORDER VII. Sp. gr. from 4.7385 to 4.569. Fusible with fixed alkalies.
Genus I. Stains the fingers. Colour lead grey.
Sp. 1 Molybdena.
Spanish wax rubbed with molybdena becomes positively electric. Streak on earthen ware yellowish green.

ORDER VIII. Sp. gr. from 4.1668 to 2.479. Fusible with fixed alkalies.
* Hardness from 10 to 12.

Artificial System.

GENUS I. Usually white. Crystals dodecahedrons. Double refraction. Fracture imperfectly conchoidal or splintery. Brittle.

Sp. 1. Quartz.

GENUS II. Usually dark brown. Fracture perfectly conchoidal. Brittle. Easily breaks into splinters.

Sp. 1. Flint.

GENUS III. Not brittle. Fracture even or imperfectly conchoidal.

Sp. 1. Chalcedony.

Sp. 2. Jasper.

GENUS IV. Forms with potass a violet glass, with soda or borax a brown glass, with microcosmic salt a honey yellow glass. Colour green. Amorphous.

Sp. 1. Chrysoprasium.

GENUS V. Tinges soda red. The colour disappears before the blue flame, and returns before the yellow flame.

Sp. 1. Oxyd of manganese and barytes.

Sp. 2. Black ore of manganese.

Sp. 3. Carbonat of manganese.

(Brown ore of iron. Red ore of iron.)

** Hardness 9 to 3.

GENUS VI. Flexible and elastic in every direction.

Sp. 1. Elastic quartz.

GENUS VII. Emits white flakes before the blowpipe.

Sp. 1. Blende.

GENUS VIII. Becomes electric when heated.

Sp. 1. Calamine.

GENUS IX. Tinges borax green. Blackens before the blow-pipe.

Sp. 1. Mountain blue.
Colour blue.

Sp. 2. Green carbonat of copper.
Colour green.

GENUS X. Tinges borax green. Becomes attractable by the magnet by the action of the blow-pipe.

Sp. 1. Brown iron ore.
Colour brown.

Sp. 2. Red iron ore.
Colour red.

GENUS XI. Tinges borax smutty yellow. Becomes brownish black before the blow-pipe.

Sp. 1. Carbonat of iron.

GENUS XII. Feels greasy.

Sp. 1. Steatites.

(Black ore of Manganese. Carbonat of manganese. Mica.)

ORDER IX. Sp. gr. from 2.39 to 1.7.

GENUS I. Lustre glassy.

Sp. 1. Opal.

Sp. 2. Hyalite.

GENUS II. Lustre greasy.

Sp. 1. Pitchstone.

GENUS III. Lustre waxy or pearly.

Sp. 1. Staurolite.

CLASS II. FUSIBLE.

ORDER I. Sp. gr. from 19 to 10.

GENUS I. Colour Yellow.

Sp. 1 Native gold.

GENUS II Colour white.

Sp. 1. Native Silver.

GENUS III. Colour yellowish white.

Sp. 1. Alloy of silver and gold.

ORDER II. Sp. gr. from 7.786 to 4.5.

GENUS I Flexible and malleable.

Sp. 1. Sulphuret of silver.

** Brittle.

GENUS II. Tinges borax white.

Sp. 1. Tinstone.

GENUS III. Tinges borax green.

Sp. 1. Sulphuret of copper.
Colour bluish grey.

Sp. 2. Chromat of lead.
Colour aurora red.

Sp. 3. Purple copper ore.
Colour purple.

GENUS IV. Tinges borax faint yellow. Becomes black when exposed to the vapour of sulphuret of ammonia.

Sp. 1. Galena.
Colour bluish grey. Lustre metallic. Fragments cubic.

Sp. 2. Black lead ore.
Colour black. Lustre metallic.

Sp. 3. Lead ochre.
Colour yellow, grey, or red. Lustre o.

Sp. 4. Carbonat of lead.
Colour white. Lustre waxy.

Sp. 5. Phosphat of lead.
Usually green. Lustre waxy. After fusion by the blow-pipe crystallizes on cooling.

Sp. 6. Molybdat of lead.
Colour yellow. Streak white. Lustre waxy.

ORDER III. Sp. gr. from 4.35 to 3.

* Hardness 14 to 9.

GENUS I. Melts without frothing into a grey enamel.

Sp. 1. Garnet.
Colour red.

GENUS II. Melts into a brownish enamel.

Sp. 1. Shorl.
Colour black. Opaque.

GENUS III. Froths and melts into a white enamel.

Sp. 1. Tourmaline.
Becomes electric by heat.

GENUS IV. Froths and melts into a greenish black enamel.

Sp. 1. Basaltine.

GENUS V. Froths amd melts into a black enamel.

Sp. 1. Thallite.
Colour dark green.

Sp. 2. Thumerstone.
Colour clove brown.

** Hardness 5 to 8.

GENUS VI. Melts into a transparent glass.

Sp. 1. Fluat of lime.
Powder phosphoresces when thrown on a hot iron.

GENUS VII. Melts into a black glass.

Sp. 1.

Artificial System.

Sp. 1. Hornblende.

GENUS VIII. Melts into a black bead with a sulphureous smell, and deposits a blue oxyd on the charcoal.

Sp. 1. Sulphuret of tin.

GENUS IX. Melts into a brown glass. Tinges borax violet.

Sp. 1. Asbestoid.

Colour green.

GENUS X. Melts into a brown (?) glass. When fused with potass, and dissolved in water, the solution becomes of a fine orange yellow.

Sp. 1. Chromat of iron.

GENUS XI. Before the blow-pipe yields a bead of copper.

Sp. 1. Red oxyd of copper.

(Sulphuret of copper.)

ORDER IV. Sp. gr. from 2.945 to 2.437.

GENUS I. Composed of scales.

Sp. 1. Talk.

Feels greasy. Spanish wax rubbed by it becomes positively electric.

GENUS II. Composed of thin plates, easily separable from each other.

Sp. 1. Mica.

Plates flexible and elastic, may be torn but not broken. Spanish wax rubbed by it becomes negatively electric.

Sp. 2. Stilbite.

Plates somewhat flexible. Colour pearl white. Powder renders syrup of violets green. Froths and melts into an opaque white enamel.

Sp. 3. Lepidolite.

Colour violet. Powder white with a tint of red. Froths and melts into a white semitransparent enamel full of bubbles.

GENUS III. Texture foliated.

Sp. 1. Felspar.

Fragments rhomboidal. Hardness 9 to 10.

Sp. 2. Leucite.

Always crystallized. White. Powder renders syrup of violets green. Hardness 8 to 10.

Sp. 3. Argentine felspar.

Always crystallized. Two faces dead white, two silvery white.

Sp. 4. Prehnite.

Colour green. Froths and melts into a brown enamel.

GENUS IV. Texture fibrous. Fibres easily separated.

Sp. 1. Asbestus.

Feels somewhat greasy.

GENUS V. Texture striated.

Sp. 1. Ædelite.

Absorbs water. Froths and melts into a frothy mass.

GENUS VI. Texture earthy or compact.

Sp. 1. Lazulite.

Froths and melts into a yellowish black mass. If previously calcined, gelatinizes with acids.

Sp. 2. Borat of lime.

Tinges the flame greenish, froths and melts into a yellowish enamel garnished with small projecting points. If the blast be continued, these dart off in sparks.

ORDER V. Sp. gr. from 2.348 to 0.68.

GENUS I. Hardness 10.

Sp. 1. Obsidian.

Colour blackish, in thin pieces green.

GENUS II. Hardness 6 to 8.

Sp. 1. Zeolite.

Gelatinizes with acids. Becomes electric by heat.

GENUS III. Hardness 3 to 4.

Sp. 1. Amianthus.

Feels greasy. Texture fibrous.

Sp. 2. Mountain cork.

Elastic like cork.

CLASS III. FUSIBLE BY THE BLUE FLAME, INFUSIBLE BY THE YELLOW.

GENUS I. Sp. gr. from 4.43 to 4.4.

Sp. 1. Sulphat of barytes.

GENUS II. Sp. gr. from 3.96 to 3.51.

Sp. 1. Sulphat of strontites.

GENUS III. Sp. gr. from 2.311 to 2.167.

Sp. 1. Sulphat of lime.

CLASS IV. FUSIBLE, AND PARTLY EVAPORATING.

ORDER I. Sp. gr. from 10 to 5.

GENUS I. Colour white or grey. Lustre metallic.

* Sp. gr. 9 to 10.

Sp. 1. Native amalgam.

Tinges gold white. Creaks when cut.

Sp. 2. Alloy of silver and antimony.

Powder greyish black.

** Sp. gr. from 6.467 to 5.309.

Sp. 3. Sulphuret of bismuth.

Melts when held to the flame of a candle.

Sp. 4. Dull grey cobalt ore.

Streak bluish grey. Hardness 10. When struck, emits an arsenical smell. Lustre scarcely metallic.

GENUS II. Colour red, at least of the streak.

Sp. 1. Red silver ore.

Burns with a blue flame.

Sp. 2. Hepatic mercurial ore.

Does not flame, but gives out mercury before the blow-pipe.

GENUS III. Colour blue.

Sp. 1. Blue lead ore.

Burns with a blue flame and sulphureous smell, and leaves a button of lead.

GENUS IV. Colour yellowish green.

Sp. 1. Phosphat and arseniat of lead combined.

When fused by the blow-pipe, crystallizes on cooling.

GENUS V. Colour usually that of copper. So

Artificial System.

gr. 6.608 ; to 6.6481.

Sp. Sulphuret of nickel.

Exhales before the blow-pipe an arsenical smoke.

ORDER II. Sp. gr. from 4.6 to 3.44.

GENUS I. Colour grey.

Sp. 1. Grey ore of antimony.

Burns with a blue flame, and leaves a white oxyd.

Sp. 2. Grey copper ore.

Crackles before the blow-pipe.

GENUS II. Colour yellow.

Sp. 1. Pyrites.

Burns with a blue flame and sulphureous smell, and leaves a brownish bead.

Sp. 2. Yellow copper ore.

Melts into a black mass.

CLASS V. EVAPORATING.

ORDER I. Sp gr. 13.6.

GENUS I. Fluid.

Sp. 1. Native mercury.

ORDER II. Sp. gr. from 10 to 5.419.

GENUS I. Colour red.

Sp. 1. Native cinnabar.

GENUS II. Colour white or grey. Lustre metallic.

Sp. 1. Native bismuth.

Melts into a white bead, and then evaporates in a yellowish white smoke. Sp. gr. 9 to 9.5.

Sp. 2. Native antimony.

Melts and evaporates in a grey smoke. Sp. gr. 6.6 to 6.8.

Sp. 3. Native arsenic.

Evaporates without melting, and gives out a garlic smell.

ORDER III. Sp. gr. from 4.8 to 3.33.

GENUS I. Colour red.

Sp. 1. Red antimonial ore.

Melts with a sulphureous smell. Sp. gr. 4.7.

Sp. 2. Realgar.

Melts with a garlic smell. Sp. gr. 3.384.

GENUS II. Colour yellow.

Sp. 1. Orpiment.

CLASS VI. SOLUBLE WITH EFFERVESCENCE IN MURIATIC ACID.

GENUS I. Sp. gr. from 4.338 to 4.3.

Sp. 1. Carbonat of barytes.

GENUS II. Sp. gr. from 3.66 to 3.4.

Sp. 1. Carbonat of strontites.

GENUS III. Sp. gr. from 2.8 to 1 or under.

Sp. 1. Carbonat of lime.

We have purposely avoided giving names to the classes, orders, and genera; because a more careful examination will doubtless suggest many improvements in the arrangement, and an artificial system ought to be brought to a great degree of perfection before its classes, orders, and genera, be finally settled.

We have excluded from this arrangement all those bodies which in the following system are arranged under the class of combustibles; because there can scarcely be any difficulty in distinguishing them both from the other classes and from one another. For similar reasons we have excluded the class of salts.

CHAP. IV. NATURAL SYSTEM.

Avicenna, a writer of the 11th century, divided minerals into four classes; stones, salts, inflammable bodies, and metals (D). This division has been, in some measure, followed by all succeeding writers. Linnæus, indeed, the first of the moderns who published a system of mineralogy, being guided by the external characters alone, divided minerals into three classes, *petræ, mineræ, fossilia*: but Avicenna's classes appear among his orders. The same remark may be made with respect to the systems of Wallerius, Wolsterdorf, Cartheuser, and Justi, which appeared in succession after the first publication of Linnæus's *Systema Naturæ*, in 1736. At last, in 1758, the system of Cronstedt appeared. He reinstated the classes of Avicenna in their place; and his system was adopted by Bergman, Kirwan, Werner, and the most celebrated mineralogists who have written since. We also shall adopt his classes, with a few slight exceptions; because we are not acquainted with any other division which is intitled to a preference.

20 Natural classes.

We shall therefore divide this treatise into four classes. I. Stones. II. Salts. III. Combustibles. IV. Ores.

The first class comprehends all the minerals which are composed chiefly or entirely of earths; the second, all the combinations of acids and alkalies which occur in the mineral kingdom; the third, those minerals which are capable of combustion, and which consist chiefly of sulphur, carbon, and oil; the fourth, the mineral bodies which are composed chiefly of metals.

CLASS I. EARTHS AND STONES.

WE shall divide this class into three orders. The first order shall comprehend all chemical combinations of earths with each other; the second order, chemical combinations of earths with acids; and the third order, mechanical mixtures of earths or stones. All the minerals belonging to the first order exhibit the same homogeneous appearance to the eye as if they were simple bodies. We shall therefore, for want of a better name, call the first order *simple*; the second order we shall distinguish by the epithet of *saline*; and the third we shall

(D) Corpora mineralia in quatuor species dividuntur, scilicet in lapides, et in liquefactiva, sulphurea, et sales. Et horum quædam sunt raræ substantiæ et debilis compositionis, et quædam fortis substantiæ, et quædam ductibilia, et quædam non. *Avicenna de congelatione et conglutinatione lapidum*, Cap. 3. *Theatrum Chemicum*, p. 997.

Earths and Stones. call *aggregates;* because most of the minerals belonging to it consist of various *simple stones*, cemented, as it were, together.

Order I. SIMPLE STONES.

21 Cronstedt's genera. Cronstedt divided this order into nine genera, corresponding to nine earths; one of which he thought composed the stones arranged under each genus. The names of his genera were, *calcareæ*, *siliceæ*, *granatinæ*, *argillaceæ*, *micaceæ*, *fluores*, *asbestinæ*, *zeolithicæ*, *magnesiæ*. All his earths were afterwards found to be compounds, except the first, second, fourth, and ninth. Bergman, 22 Improved. therefore, in his Sciagraphia, first published in 1782, reduced the number of genera to five; which was the number of primitive earths known when he wrote. Since that period three new earths have been discovered. Accordingly, in the latest systems of mineralogy, the genera belonging to this order amount to eight. Each genus is named from an earth; and they are arranged in the newest Wernerian system, which we have seen, as follows:

1. Jargon genus.	5. Magnesian genus.
2. Siliceous genus.	6. Calcareous genus.
3. Glucina genus.	7. Barytic genus.
4. Argillaceous genus.	8. Strontian genus.

Mr Kirwan, in his very valuable system of mineralogy, has adopted the same genera. Under each genus, those stones are placed, which are composed chiefly of the earth which gives a name to the genus, or which at least are supposed to possess the characters which di-23 Still deficient. stinguish that earth.

A little consideration will be sufficient to discover that there is no natural foundation for these genera. Most stones are composed of two, three, or even four ingredients; and, in many cases, the proportion of two or more of these is nearly equal. Now, under what genus soever such minerals are arranged, the earth which gives it a name must form the smallest part of their composition. Accordingly, it has not been so much the chemical composition, as the external character, which has guided the mineralogist in the distribution of his species. The genera cannot be said properly to have any character at all, nor the species to be connected by any thing else than an arbitrary title. This defect, which must be apparent in the most valuable systems of mineralogy, seems to have arisen chiefly from an attempt to combine together an artificial and natural system. As we have separated these two from each other, it becomes necessary for us to attend more accurately to the natural distribution of genera than has hitherto been done. We have accordingly ventured to form new genera for this order, and we have formed them according 24 New genera. to the following rules.

The only substances which enter into the minerals belonging to this order, in such quantity as to deserve attention, are the following:

Alumina,	Glucina,
Silica,	Zirconia,
Magnesia,	Oxyd of iron,
Lime,	Oxyd of chromum,
Barytes,	Potass,

Simple Stones. All those minerals which are composed of the *same* ingredients we arrange under the *same* genus. According to this plan, there must be as many genera as there are varieties of combinations of the above substances existing in nature. The varieties in the *proportion* of the ingredients constitute species. We have not imposed names upon our genera, but, in imitation of Bergman*, have denoted each by a symbol. This symbol is composed of the first letter of every substance which enters in any considerable quantity into the composition of the minerals arranged under the genus denoted by it. Thus, suppose the minerals of a genus to be composed of *alumina*, *silica*, and *oxyd of iron*, we denote the genus by the symbol *asi*. The letters are arranged according to the proportion of the ingredients; that which enters in the greatest proportion being put first, and the others in their order. Thus the genus *asi* is composed of a considerable proportion of alumina, of a smaller proportion of silica, and contains least of all of iron. By this contrivance, the symbol of a genus contains, within the compass of a few letters, a pretty accurate description of its nature and character. Where the proportions of the ingredients vary in the same genus so much, that the letters which constitute its symbol change their place, we subdivide the genus into parts; and whenever the minerals belonging to any genus become too numerous, advantage may be taken of these subdivisions, and each of them may be formed into a separate genus. At present this seems unnecessary (E).

* Opusc. iv. 231.

The following is a view of the different genera belonging to this order, denoted each by its symbol. Every genus is followed by the species included under it; and the whole are in the order which we mean to follow in describing them:

I. A.
- Telesia,
- Corundum,
- Native alumina.

II. AMC.
- Ruby.

III. AIM.
- Ceylanite,

IV. S.
- Quartz,
- Elastic quartz,
- Flint,
- Opal,
- Pitchstone,
- Chrysoprasium.

V. 1. AS.
- Topaz,
- Sommite,
- Shorlite.

2. SA.
- Rubellite,
- Hornslate,
- Hornstone,
- Chalcedony,
- Jasper,
- Tripoli.

VI. 1. ASI.
- Micarell,
- Shorl,
- Granatite,

2. SAI.
- Tourmaline,
- Argentine felspar,
- Mica,
- Talc,
- Basaltine,
- Hornblende,
- Obsidian,
- Petrilite,
- Felsite.

VII. SAP.
- Felspar,
- Lepidolite,
- Leucite.

VIII. SAG.
- Emerald.

IX. SAB.
- Staurolite.

X. 1. ASL.
- Chrysoberyl.

2. SAL.
- Hyalite,
- Ædelite.

(E) We need hardly remark, that the last three genera of Werner belong to the second order of the first class of this treatise.

3. SAWL.
Zeolite,
Stilbite,
Analcime.
4. SLA.
Lazulite.
XI. SALI.
Garnet,
Thumerftone,
Prehnite,
Thallite.
XII. 1. AMS.
Cyanite.
2. MSA.
Serpentine.
XIII. MSAI.
Potftone,
Chlorite.
XIV. SLAM.
Siliceous fpar.
XV. SAMLI.
Argillite.
XVI. SM.
Kiffekill,
Steatites.
XVII. MSI.
Chryfolite,
Jade.
XVIII. SML.
Afbeftus,
Afbeftinite.
XIX. 1. SILM.
Pyroxen,
Afbeftoid.
2. SMIL.
Actinolite.
XX. SL.
Shiftofe hornftone.
XXI. ZS.
Zircon.

G. I. A. Telefia.

GENUS I. A.

SPECIES 1. Telefia (F).

Oriental ruby, fapphire, and *topaz* of mineralogifts.—*Rubis d'orient* of De Lifle.

Three ftones, diftinguifhed from each other by their colour, have long been held in high eftimation on account of their hardnefs and beauty. Thefe ftones were known among lapidaries by the names of *ruby, fapphire*, and *topaz*, and the epithet *oriental* was ufually added, to diftinguifh them from other three, known by the fame names and the fame colours, but very inferior in hardnefs and beauty. Mineralogifts were accuftomed to confider thefe ftones as three diftinct fpecies, till Romé de Lifle obferved that they agreed in the form of their cryftals, their hardnefs, and moft of their other properties. Thefe obfervations were fufficient to conftitute them one fpecies; and accordingly they were made one fpecies by Romé de Lifle himfelf, by Kirwan, and feveral other modern mineralogical writers. But this fpecies was deftitute of a proper name, till Mr Hauy, whofe labours, diftinguifhed equally by their ingenuity and accuracy, have contributed not a little to the progrefs of mineralogy, denominated it *telefia*, from the Greek word τελεσια, which fignifies *perfect*.

The telefia is found in the Eaft Indies, efpecially in Pegu and the ifland of Ceylon; and it is moft commonly cryftallized. The cryftals are of no great fize; Their *primitive* form, according to Mr Hauy, is a regular fix-fided prifm, divifible in directions parallel both to its bafes and its fides; and confequently giving for the form of its primitive nucleus, or of its *integrant molecule*, an equilateral three fided prifm *. The moft ufual variety is a dodecahedron, in which the telefia appears under the form of two very long flender fix-fided pyramids, joined bafe to bafe †. The fides of thefe pyramids are ifofceles triangles, having the angle at their vertex 22° 54', and each of thofe at the bafe 78° 48' (G). The inclination of a fide of one pyramid to a contiguous fide of the other pyramid is 139° 54' †. In fome fpecimens the fummits of the pyramids are wanting, fo that the cryftal has the appearance of a fix fided prifm, fomewhat thicker in the middle than towards the extremities *. The three alternate angles at each extremity of this prifm are alfo fometimes wanting, and a fmall triangular face inftead of them, which renders the bafes of the fuppofed prifm nine-fided. The inclination of each of thefe fmall triangles to the bafe is 122° 18' ‡ For figures of thefe cryftals we refer the reader to Romé de Lifle and Hauy *.

* Ann de Chim. xvii. 313.
† Plate XXXVI. fig. 1.
Simple Stones.
† Ibid and Romé de Lifle, ii. 315.
* Fig. 2.
‡ Hauy, ibid.
* Ibid.

The texture of the telefia is foliated, and the joints are parallel to the bafe of the prifm †. Its luftre varies from 3 to 4 (H). Tranfparency ufually 3 or 4, fometimes only 2. It caufes only a fingle refraction. Specific gravity from 4. to 4.288. Hardnefs from 15 to 17. It is either colourlefs, or red, yellow or blue. Thefe colours have induced lapidaries to divide the telefia into the three following varieties.

† Hauy.

Variety 1. Red telefia.

Oriental ruby.

Colour carmine red, fometimes verging towards violet. Sometimes various colours appear in the fame ftone, as red and white, red and blue, orange red. Hardnefs 17. Sp. gr. 4.288.

Variety 2. Yellow telefia.

Oriental topaz.

Colour golden yellow. Tranfp. 4. Hardnefs 15. Sp. gr. 4.0106.

Variety 3. Blue telefia.

Oriental fapphyr.

Colour Berlin blue, often fo very faint that the ftone appears almoft colourlefs. Tranfp. 3, 4, 2. Hardnefs 17. Sp. gr. 3.991 to 4.083 ‡. This variety is not probably the fame with the fapphyr of the ancients. Their fapphyr was diftinguifhed by gold-coloured fpots, none of which are to be feen in the fapphyr of the moderns ||.

‡ Greville, Nicholfon's Jour. iii. 11.
|| Hill's Theophraftus, περι των λιθων, p. 100.

A fpecimen of this laft variety, analyfed by Mr Klaproth, was found to contain in 100 parts,

98.5 alumina,
1.0 oxyd of iron,
0.5 lime,

100.0 *.

* Beiträge, i. 81.

The colouring matter of all thefe varieties is, according to Bergman's experiments, iron, in different ftates of oxydation. He found that the topaz contained .06, the ruby .1, and the fapphyr .02 of that metal †. But when thefe experiments were made, the analyfis of ftones was not arrived at a fufficient degree of perfection to enfure accuracy. No conclufion, therefore, can be drawn from thefe experiments, even though we were certain that they were made upon the real varieties of telefia.

† Bergman, ii. 96.

(G) In fome inftances, the angle at the vertex is 31°, thofe at the bafe 74° 30', and the inclination of two triangles 122° 36'. See *Hauy, ibid.*

(H) When the *kind* of luftre is not fpecified, as in the prefent inftance, the *common* is always meant.

Earths and Stones.

26 Corundum.

SPECIES 2. Corundum (I).

Corundum of Gmelin—*Adamantine spar* of Klaproth and Kirwan—*Corindon* of Hauy—*Corivindum* of Woodward.

This stone, though it appears to have been known to Mr Woodward, may be said to have been first distinguished from other minerals by Dr Black. In 1768, Mr Berry, a lapidary in Edinburgh, received a box of it from Dr Anderson of Madras. Dr Black ascertained, that these specimens differed from all the stones known to Europeans; and, in consequence of its hardness, it obtained the name of *adamantine spar*. Notwithstanding this, it could scarcely be said to have been known to European mineralogists till Mr Greville of London, who has done so much to promote the science of mineralogy, obtained specimens of it, in 1784, from India, and distributed them among the most eminent chemists, in order to be analysed. Mr Greville also learned, that its Indian name was Corundum. It is found in Indostan, not far from the river Cavery, which is south from Madras, in a rocky matrix, of considerable hardness, partaking of the nature of the stone itself *. It occurs also in China; and a substance, not unlike the matrix of corundum, has been found in Teree, one of the western islands of Scotland †.

* Garrow and Greville, *Nicholson's Jour.* ii. 540.

The corundum is usually crystallized. Its primitive form, discovered by Mr Hauy ‡ and the Count de Bournon *, is a rhomboidal parallelopiped, whose sides are equal rhombs, with angles of 86° and 94°, according to Bournon, or whose diagonals are to each other as $\sqrt{17}$ to $\sqrt{15}$, according to Hauy; which is very nearly the same thing †. The most common variety, for the primitive form has never yet been found, is the regular six-sided prism, the alternate angles of which are sometimes wanting ||, and the triangular faces, which occupy their place, are inclined to the base at an angle of 122° 34′ ‡. Sometimes the corundum is crystallized in the form of a six-sided pyramid, the apex of which is generally wanting. For a description and figure of these, and all the other varieties of corundum hitherto observed, we refer the reader to the dissertation of the Count de Bournon on the subject *.

† Greville, *ibid.*
‡ *Jour. de Min.* N° xxviii. 262.
* *Nicholson's Jour.* ii. 541.
† Fig. 3.
|| Fig. 4.
‡ *De Bournon.*
* See also *Hauy. Jour. de Min.* N° xxviii. 262.

The texture of the corundum is foliated, and the natural joints are parallel to the faces of the primitive rhomboidal parallelopiped. Lustre, when in the direction of the laminæ, 3; when broken across, 0. Opake, except when in very thin pieces. Hardness 15. Sp. gr. from 3.710 to 4.180 †. Colour grey, often with various shades of blue and green.

† *Klaproth.* See also *Mr Greville, Nicholson's Jour.* iii 11.

According to the analysis of Klaproth, the corundum of India is composed of

89.5	alumina,
5.5	silica,
1.25	oxyd of iron,
96.25 ‡.	

‡ *Beiträge* i. 77.

A specimen from China of

84.0	alumina,
6.5	silica,
7.5	oxyd of iron,
98.0 ||.	

|| *Ibid.* i 73.

Notwithstanding the quantity of silica and of iron which these analyses exhibit in the corundum, we have been induced to include it in the present genus, on account of the strong resemblance between it and the third variety of telesia. The striking resemblance between the crystals of telesia and corundum will appear evident, even from the superficial description which we have given; and the observations of De Bournon * render this resemblance still more striking. It is not improbable, therefore, as Mr Greville and the Count de Bournon have suggested, that corundum may be only a variety of telesia, and that the seeming difference in their ingredients is owing to the impurity of those specimens of corundum which have hitherto been brought to Europe. Let not the difference which has been found in the primitive form of these stones be considered as an insuperable objection, till the subject has been again examined with this precise object in view; for nothing is easier than to commit an oversight in such difficult examinations.

* *Nichol. Jour.* ii. 9.

27 Native alumina.

SPECIES 3. Native alumina (K).

This substance has been found at Halles in Saxony in compact kidney-form masses. Its consistence is earthy. Lustre 0. Opaque. Hardness 4. Brittle. Sp. gr. moderate. Feels soft, but meagre. Adheres very slightly to the tongue. Stains very slightly. Colour pure white. Does not readily diffuse itself in water.

It consists of pure alumina, mixed with a small quantity of carbonat of lime, and sometimes of sulphat of lime †.

G. II. AMC Ruby.

GENUS II. AMC.

SPECIES 1. Ruby (L).

Spinel and *balass Ruby* of Kirwan—*Ruby* of Hauy—*Rubis spinelle octoedre* of De Lisle—*Spinellus* of Gmelin.

This stone, which comes from the island of Ceylon, is usually crystallized. The primitive form of its crystals is a regular octohedron, composed of two four-sided pyramids applied base to base, each of the sides of which is an equilateral triangle ‡ (M). In some cases two opposite sides of the pyramids are broader than the other two; and sometimes the edges of the octohedron are wanting, and narrow faces in their place. For figures and descriptions of these, and other varieties of these crystals, we refer the reader to *Romé de Lisle* and the *Abbé Estner* *.

‡ Fig. 5.

The texture of the ruby is foliated. Its lustre is 3. Transp. 3.4. It causes a single refraction. Hardness 13. Sp. gr. 3.570 † to 3.625 †. Colour red: if deep, the ruby is usually called *balass*; if pale rose, *spinell*.

* *Cryst.* ii. 226. *Estner's Miner.*
† *Klaproth.*

GENUS III. AIM.

SPECIES 1. Ceylanite.

G. III. AIM. Ceylanite.

The mineral denominated *ceylanite*, from the island of Ceylon, from which it was brought into Europe, had been observed by Romé de Lisle ‡; but was first described by La Metherie in the Journal de Physique for January 1793.

‡ Crystal. iii. 180 Note 21.

It is most commonly found in rounded masses; but sometimes also crystallized. The primitive form of its crystals is a regular octohedron: it commonly occurs under this form, but more commonly the edges of the octohedron are wanting, and small faces in their place ‡.

The fracture of the ceylanite is conchoidal *. Its internal lustre is glassy. Nearly opaque, except when in very thin pieces. Hardness 12. Sp. gr. from 3.7617 † to 3.793 ‡. Colour of the mass, black; of very thin pieces, deep green. Powder, greenish grey. According to the analysis of Descotils the ceylanite is composed of

68 alumina,
16 oxyd of iron,
12 magnesia,
2 silica.

30

GENUS IV. S.

SPECIES 1. Quartz ||.

G. IV. S. Quartz.

This stone, which is very common in most mountainous countries, is sometimes crystallized, and sometimes amorphous. The primitive form of its crystals, according to Mr Hauy, is a rhomboidal parallelopiped; the angles of whole rhombs are 93° 22', and 86° 38'; so that it does not differ much from a cube *. The most common variety is a dodecahedron ‡, composed of two six-sided pyramids, applied base to base, whose sides are isosceles triangles, having the angle at the vertex 40°, and each of the angles at the base 70°; the inclination of a side of one pyramid to the contiguous side of the other pyramid is 104°. There is often a six-sided prism interposed between the two pyramids, the sides of which always correspond with those of the pyramids ||. For a description and figure of the other varieties of quartz crystals, and for a demonstration of the law which they have followed in crystallizing, we refer the reader to *Romé de Lisle* † and *Mr Hauy* ‡.

|| Kirwan's Min. i. 241.
* Jour de Min. No xxviii. 255.
‡ Fig. 6.
Fig. 7.
† Crystal. ii. 71.
‡ Mem. Par. 1786, p. 78 See also *Lametherie, Jour. de Phys.* xlii. 470.

The texture of quartz is more or less foliated. Fracture, conchoidal or splintery. Its lustre varies from 3 to 1, and its transparency from 4 to 1; and in some cases it is opaque. It causes a double refraction. Hardness, from 10 to 11. Sp. gr. from 2.64 to 2.67, and in one variety 2.691. Its colour is exceedingly various; a circumstance which has induced mineralogists to divide it into numerous varieties. Of these the following are the chief:

Simple Stones.

1. Pure colourless, perfectly transparent crystallized quartz, having much the appearance of artificial crystal; known by the name of *rock crystal*.

2. Quartz less transparent, and with a splintery fracture, has usually been distinguished by the name of *quartz*, and separated from rock crystal. As there is no occasion for this separation, we have, in imitation of Mr Hauy, chosen the word quartz for the *specific name*, comprehending under it all the varieties.

3. Blood red quartz; formerly called *crompostella hyacinth*, and by Hauy *quartz hematoide*. It owes its colour to oxyd of iron. The mineral known to mineralogists by the name of *sinople*, and considered by them as a variety of *jasper*, has been discovered by Dolomieu to be merely this variety of quartz in an amorphous state *.

4. Yellow quartz; called false topaz.

5. Rosy red quartz; called Bohemian ruby.

* Jour. de Min No xxviii. 255.

For a fuller enumeration of these varieties, we refer the reader to *Smeisser's Mineralogy* †, *Kirwan's Mineralogy* ‡, and Gmelin's edition of the *Systema Naturæ* of Linnæus §. This last writer, however, has arranged several minerals under quartz which do not belong to it.

† i. 89.
‡ i. 244.
§ iii. 194.

Pure quartz is composed entirely of silica; but some of the varieties of this species are contaminated with metallic oxyds, and with a small quantity of other earths.

SPECIES 2. Elastic Quartz (N).

31 Elastic quartz.

This singular stone is moderately elastic, and flexible in every direction. Texture, earthy. Lustre, 0 or 1. Hardness, 9. Brittle. Sp. gr. 2.624. Colour, greyish white. Phosphoresces when scraped with a knife in the dark. The specimen analysed by Mr Klaproth contained

96.5 silica,
2.5 alumina,
5 oxyd of iron,

99.5 †

† Beiträge, ii. 116.

SPECIES 3. Flint (O).

32 Flint.

Pyromachus—Pierre a fusil—Silex of Hauy.

This stone, which has become so necessary in modern war, is found in pieces of different sizes, and usually of a figure more or less globular, commonly among chalk, and often arranged in some kind of order. In Saxony it is said to have been found crystallized in hexahedrons, composed of two low three-sided pyramids applied base to base *.

* Gmelin's Systema Naturæ, iii. 183.

Its texture is compact. Its fracture, smooth conchoidal. Lustre, external 0, the stones being always covered by a white crust; internal 1, inclining to greasy. Transp. 2; when very thin, 3. Hardness, 10 or 11. Sp. gr. from 2.58 to 2.63. Colour varies from honey yellow to brownish black. Very brittle, and splits into splinters in every direction. Two pieces of flint rubbed smartly together phosphoresce, and emit a peculiar odour. When heated it decrepitates, and becomes white and opaque. When exposed long to the air

(N) *Kirwan's Min.* I. 316.—*Gerhard Mem. Berlin*, 1783. 107.—*Klaproth's Beitrage 2 Band.* 113. See also *Jour. de Phys.* XLI. 91.

(O) *Kirwan's Min.* I. 301.—*Dolomieu Jour de Min.* No XXXIII. 693. and *Salivet, ibid.* 713. These last gentlemen give the only accurate account of the method of making gun flints.

Earths and Stones.

air it often becomes covered with a white crust. A specimen of flint analysed by Klaproth contained

98.00 silica,
.50 lime,
.25 alumina,
0.25 oxyd of iron,
1.00 water.

100.00 †

† Beiträge, i. 46.

Another specimen analysed by Dolomieu was composed of 97 silica,
1 alumina and oxyd of iron,
2 water.

100 ‡

‡ Jour de Min No xxxiii 702.

The white crust with which flint is enveloped, consists of the same ingredients, and also a little carbonat of lime. Dolomieu discovered that water is essential to flint; for when it is separated by heat the stone loses its properties §.

§ Ibid.

The manufacture of gun flints is chiefly confined to two or three departments in France. The operation is exceedingly simple: a good workman will make a 1000 flints in a day. The whole art consists in striking the stone repeatedly with a kind of mallet, and bringing off at each stroke a splinter, sharp at one end and thicker at the other. These splinters are afterward shaped at pleasure, by laying the line at which it is wished they should break, upon a sharp iron instrument, and then giving it repeatedly small blows with a mallet. During the whole operation the workman holds the stone in his hand, or merely supports it on his knee ||.

|| Ibid.

33

SPECIES 4. Opal (P).

This stone is found in many parts of Europe. It is usually amorphous. Its fracture is conchoidal, commonly somewhat transparent. Hardness from 6 to 10. Sp. gr. from 1.7 to 2.66. The lowness of its specific gravity, in some cases, is to be ascribed to accidental cavities which the stone contains. These are sometimes filled with drops of water. Some specimens of opal have the property of emitting various coloured rays, with a particular effulgency, when placed between the eye and the light. The opals which possess this property, are distinguished by lapidaries by the epithet *oriental*; and often by mineralogists by the epithet *nobilis*. This property rendered the stone much esteemed by the ancients.

Variety 1. Opal edler—*Opalus nobilis*.

Lustre glassy, 3. Transp. 3 to 2. Hardness, 6 to 8. Colour, usually light bluish white, sometimes yellow or green. When heated it becomes opaque, and sometimes is decomposed by the action of the atmosphere. Hence it seems to follow, that water enters essentially into its composition. A specimen of this variety, analysed by Klaproth, contained

90 silica,
10 water.

100 ¶.

Variety 2. Semi-opal.

Fracture, imperfectly conchoidal. Lustre, glassy 2. Transp. 2 to 3. Hardness, 7 to 9. Its colours are very various, greys, yellows, reds, browns, greens of different kinds.

Simple Stones.

Specimens of this variety sometimes occur with rifts: these readily imbibe water, and therefore adhere to the tongue. These specimens sometimes become transparent when soaked in water, by imbibing that fluid. They are then called *hydrophanes*.

Variety 3. Cat's eye *.

* Kir. Min. Klaproth, Beiträge, i. 90.

This variety comes from Ceylon, and is seldom seen by European mineralogists till it has been polished by the lapidary. Mr Klaproth has described a specimen which he received in its natural state from Mr Greville of London. Its figure was nearly square, with sharp edges, a rough surface, and a good deal of brilliancy.

Its texture is imperfectly foliated. Lustre greasy, 2. Transp. 3 to 2. Hardness 10. Sp. gr. 2.56 to 2.66. Colour, grey; with a tinge of green, yellow or white; or brown, with a tinge of yellow or red. In certain positions it reflects a splendid white, as does the eye of a cat; hence the name of this stone.

Two specimens, analysed by Klaproth, the first from Ceylon, the other from Malabar, were composed of

95.00	94.50	silica,
1.75	2.00	alumina,
1.50	1.50	lime,
0.25	0.25	oxyd of iron.
98.5 *	98.25 †.	

* Beiträge, i. 94
† Ibid p. 96.

SPECIES 5. Pitchstone §.
Menelites.

34 Pitchstone.
§ Kir. Min. i. 92.—Dolomieu, Mem. Par. 1787, p. 80.

This stone, which occurs in different parts of Germany, France, and other countries, has obtained its name from some resemblance which it has been supposed to have to pitch. It is most usually in amorphous pieces of different sizes; and it has been found also crystallized in six-sided prisms, terminated by three-sided pyramids.

Its texture is conchoidal and uneven, and sometimes approaches the splintery. Lustre greasy, from 3 to 1. Transp. 2 to 1, sometimes 0. Hardness 8 to 10. Exceedingly brittle; it yields even to the nail of the finger. Sp. gr. 2.049 to 2.39. Its colours are numerous, greyish black, bluish grey, green, red, yellow of different shades. Sometimes several of these colours appear together in the same stone. A specimen of pitchstone from Mesnil-montant near Paris *, analysed by Mr Klaproth, contained

* See Jour. Phys. xxxi. 219.

85.5 silica,
11.0 air and water,
1.0 alumina,
.5 iron,
.5 lime and magnesia.

98.5 †

† Beiträg ii 169.

SPECIES 6. Chrysoprasium (Q).

35 Chrysoprasium.

This mineral, which is found in different parts of Germany, particularly near Kosemütz in Silesia, is always amorphous. Its fracture is either even or inclining to the splintery. Scarcely any lustre. Transp. 2 to 3. Hardness 10 to 12. Sp. gr. 2.479. Colour, green. In a heat of 130° Wedgewood it whitens and becomes opaque.

Earths and Stones.

A specimen of this stone, analysed by Mr Klaproth, contained

96.16 silica,
1.00 oxyd of nickel,
0.83 lime,
0.08 alumina,
0.08 oxyd of iron.

98.15 ‡

‡ Schrift. ... 16 G. V. 1. AS. Topaz.

GENUS V. 1. AS.

SPECIES 1. Topaz (R).

Occidental ruby, topaz, and sapphyr.

The name *topaz* has been restricted by Mr Hauy to the stones called by mineralogists occidental ruby, topaz, and sapphyr; which, agreeing in their crystallization and most of their properties, were arranged under one species by Mr Romé de Lisle. The word *topaz*, derived from an island in the Red Sea (S), where the ancients used to find topazes, was applied by them to a mineral very different from ours. One variety of our topaz they denominated *chrysolite*.

The topaz is found in Saxony, Bohemia, Siberia, and Brazil, mixed with other minerals in granite rocks.

It is commonly crystallized. The primitive form of its crystals is a prism whose sides are rectangles, and bases rhombs, having their greatest angles 124° 22', and the integral molecule has the same form*; and the height of the prism is to a side of the rhomboidal bases as 3 to 2 †. The different varieties of topaz crystals hitherto observed, amount to 6. Five of these are eight-sided prisms, terminated by four-sided pyramids, or wedge shaped summits, or by irregular figures of 7, 13, or 15 sides‖; the last variety is a twelve sided prism, terminated by six-sided pyramids wanting the apex. For an accurate description and figure of these varieties we refer the reader to Mr Hauy ‡.

* Hauy, Jour. de Min. N° xxviii, 2..
† Fig. 8.
‖ Fig. 9.
‡ Jour. de Min. ibid.

The texture of the topaz is foliated. Its lustre is from 2 to 4. Transp. from 2 to 4. It causes a double refraction. Hardness 12 to 14. Sp. gr. from 3.5311 to 3.564. The Siberian and Brazil topazes, when heated, become positively electrified on one side, and negatively on the other §. It is infusible by the blowpipe. The yellow topaz of Brazil becomes red when exposed to a strong heat in a crucible; that of Saxony becomes white by the same process. This shews us, that the colouring matter of these two stones is different.

§ Hauy, ib.

The colour of the topaz is various, which has induced mineralogists to divide it into the following varieties:

1. Red topaz, of a red colour inclining to yellow; called *Brazilian* or *occidental ruby*.

2. Yellow topaz, of a golden yellow colour, and sometimes also nearly white; called *occidental* or *Brazil topaz*. The powder of this and the following variety causes syrup of violets to assume a green colour ‖.

3. *Saxon topaz*. It is of a pale wine yellow colour, and sometimes greyish white.

‖ Vauquelin, Jour. de Min N° xxix. 105.

4. *Aigue marine*. It is of a bluish or pale green colour.

Simple Stones.

5. *Occidental sapphyr*. It is of a blue colour; and sometimes white.

A specimen of white Saxon topaz, analysed by Vauquelin, contained

68 alumina,
31 silica.

99 ¶

¶ Jour. de Min N° xxiv. 3.

SPECIES 2. Sommite.

37 Sommite.

This stone was called sommite by La Metherie, from the moutain Somma, where it was first found. It is usually mixed with volcanic productions. It crystallizes in six-sided prisms, sometimes terminated by pyramids. Colour white. Somewhat transparent. Sp. gr. 3.2741. Infusible by the blow-pipe. According to the analysis of Vauquelin, it is composed of

49 alumina,
46 silica,
2 lime,
1 oxyd of iron.

98 *

* Ibid. N° xxvii. 279.

SPECIES 3. Shorlite †.

38 Shorlite.

This stone, which received its name from Mr Klaproth, is generally found, in irregular oblong masses or columns, inserted in granite. Its texture is foliated. Fracture uneven. Lustre 2. Transparency 2 to 1. Hardness 9 to 10. Sp. gr. 3.53. Colour greenish white, or sulphur yellow. Not altered by heat. According to the analysis of Klaproth, it is composed of

† Kirwan's Min. i. 286.

50 alumina,
50 silica.

100

GENUS V. 2. SA.

39 G. V. 2. SA. Rubellite.

SPECIES 4. Rubellite (T).

Red shorl of Siberia.

This stone is found in Siberia mixed with white quartz. It is crystallized in small needles, which are grouped together and traverse the quartz in various directions. Texture fibrous. Fracture even, inclining to the conchoidal. Transparency 2; at the edges 3. Hardness 10. Brittle. Sp. gr. 3.1. Colour crimson, blood or peach red. By exposure to a red heat it becomes snow white; but loses none of its weight. It tinges soda blue, but does not melt with it.

According to the analysis of Mr Bindheim, it is composed of

57 silica,
35 alumina,
5 oxyds of iron and manganese.

97

SPECIES 5. Hornslate (U).

40 Hornslate.

Shistose-porphyry.

This stone, which occurs in mountains, is generally amorphous; but sometimes also in columns. Structure

Earths and Stones.

ture slaty. Texture foliated. Fracture uneven and splintery; sometimes approaching the conchoidal. Lustre 0. Transparency 1 or 0. Hardness about 10. Sp. gr. from 2.512 to 2.7. Colour different shades of *grey*, from *ash* to *bluish* or *olive green*. Melts at 140 Wedgewood into an enamel. A specimen, analysed by Wedgewood, contained

73.0	silica,
23.9	alumina,
3.5	iron.
100.4	

41 Hornstone.

SPECIES 6. Hornstone (x).

Petrosilex—Chert.

This stone, which makes a part of many mountains, is usually amorphous; but, as Mr Kirwan informs us, it has been found crystallized by Mr Beyer on Schneeberg. Its crystals are six sided prisms, sometimes terminated by pyramids; hexahedrons, consisting of two three-sided pyramids applied base to base; and cubes, or six-sided plates *. Its texture is foliated. Fracture splintery, and sometimes conchoidal. Lustre 0. Transparency 1 to 2. The crystals are sometimes opaque. Hardness 7 to 9. Sp. gr. 2.532 to 2.653. Colour usually dark blue: but hornstone occurs also of the following colours; grey, red, blue, green, and brown of different shades †.

According to Kirwan, it is composed of

72	silica,
22	alumina,
6	carbonat of lime.
100 ‡	

* Kirwan, i. 303.

† Schmeisser's Min. i. 103.

‡ Ibid. p. 105.

42 Chalcedony.

SPECIES 7. Chalcedony.

This stone is found abundantly in many countries, particularly in Iceland and the Faro islands. It is most commonly amorphous, stalactitical, or in rounded masses; but it occurs also crystallized in six-sided prisms, terminated by pyramids, or more commonly in four or six sided pyramids, whose sides are convex. Surface rough. Fracture more or less conchoidal. Lustre 1. Somewhat transparent. Hardness 10 to 11. Sp. gr. 2.56 to 2.665. Not brittle.

According to Bergman, the chalcedony of Faroe is composed of

84	silica,
16	alumina, mixed with iron.
100	

Variety 1. Common chalcedony.

Fracture even, inclining to conchoidal. Transparency 2 to 3; sometimes 1. Its colours are various; it is most commonly greyish, with a tint of yellow, green, blue, or pearl; often also white, green, red, yellow, brown, black, or dotted with red. When striped white and black, or brown, alternately, it is called *onyx*; when striped white and grey, it is called *chalcedonix*. Black or brown chalcedony, when held between the eye and a strong light, appears dark red.

Variety 2. Cornelian.

Fracture conchoidal. Transparency 3 to 1; often cloudy. Its colours are various shades of red, brown, and yellow. Several colours often appear in the same mass. To this variety belong many of the stones known by the name of *Scotch pebbles*.

Simple Stones.

SPECIES 8. Jasper (y).

This stone is an ingredient in the composition of many mountains. It occurs usually in large amorphous masses, and sometimes also crystallized in six sided irregular prisms. Its fracture is conchoidal. Lustre from 2 to 0. Either opaque, or its transparency is 1. Hardness 9 to 10. Sp. gr. from 2.5 to 2.82. Its colours are various. When heated, it does not decripitate. It seems to be composed of silica and alumina, and often also contains iron. 43 Jasper.

Variety 1. Common jasper.

Sp. gr. from 2.58 to 2.7. Its colours are, different shades of white, yellow, red, brown, and green; often variegated, spotted, or veined, with several colours.

Variety 2. Egyptian pebble.

This variety is found chiefly in Egypt. It usually has a spheroidal or flat rounded figure, and is enveloped in a coarse rough crust It is opaque. Hardness 1[illegible]. Sp. gr. 2.564. It is chiefly distinguished by the variety of colours, which always exist in the same specimen, either in concentric stripes or layers, or in dots or dentritical figures These colours are, different browns and yellows, milk white, and isabella green; black also has been observed in dots.

Variety 3. Striped jasper.

This variety is also distinguished by concentric stripes or layers of different colours: these colours are, yellow, brownish red, and green. It is distinguished from the last variety by its occurring in large amorphous masses, and by its fracture, which is nearly even.

SPECIES 9. Tripoli. 44 Tripoli.

This mineral is found sometimes in an earthy form, but more generally indurated. Its texture is earthy. Its fracture often somewhat conchoidal. Lustre 0. Generally opaque. Hardness 4 to 7 Sp gr. 2.080 to 2.529. Absorbs water. Feel, harsh dry. Hardly adheres to the tongue. Takes no polish from the nail. Does not stain the fingers Colour generally pale yellowish grey, also different kinds of yellow, brown, and white.

It contains, according to Haasse, 90 parts of silica, 7 alumina, and 3 of iron. A mineral belonging to this species was analysed by Klaproth, and found to contain

66.5	silica,
7.0	alumina,
2.5	oxyd of iron,
1.5	magnesia,
1.25	lime,
19.	air and water.
97.75	

GENUS VI. I. ASI.

SPECIES 1. Micarell *. 45 VI. r. ASI. Micarell.

This name has been given by Mr Kirwan to a stone which former mineralogists considered as a variety of * Kirw. mica. It is found in granite. Its texture is foliated, [illegible] and

and it may be split into thin plates. Lustre metallic, 3. Opaque. Hardness 6. Sp gr. 2.980. Colour brownish black. At 153° Wedgewood, it melts into a black compact glass, the surface of which is reddish †.

† Kirw. i. 3??

A specimen analysed by Klaproth contained

63.00 alumina,
29.50 silica,
6.75 iron.

—————

99.25

46 Shorl. Kirw. i. 265.

SPECIES 2. Shorl ‡.

No word has been used by mineralogists with less limitation than *shorl*. It was first introduced into mineralogy by Cronstedt, to denote any stone of a columnar form, considerable hardness, and a specific gravity from 3 to 3.4. This description applied to a very great number of stones. And succeeding mineralogists, though they made the word more definite in its signification, left it still so general, that under the designation of *shorl* almost 20 distinct species of minerals were included.

Mr Werner first defined the word *shorl* precisely, and restricted it to one species of stones. We use the word in the sense assigned by him.

Shorl is found abundantly in mountains, either massive or crystallized, in three or nine sided prisms, often terminated by three sided summits. The sides of the crystals are longitudinally streaked. Its texture is foliated. Its fracture conchoidal. Lustre 2. Opaque. Hardness 10. Sp. gr. 2.92 to 3.212. Colour black. Streak grey. It does not become electric by heat. When heated to redness, its colour becomes brownish red; and at 127° Wedgewood, it is converted into a brownish compact enamel *. According to Wiegleb, it is composed of

* Ibid. i. 166.

41.25 alumina,
34.16 silica,
20.00 iron,
5.41 manganese.

—————

100.82 †

† Crell's ... i.

SPECIES 5. Granatite.

Staurolide of Hauy—*Pierre de Croix* of De Lisle—*Staurolithe* of Lametherie.

47 Granatite.

We have adopted from Mr Vauquelin the term *granatite* to denote this stone, because all the other names are ambiguous, having been applied to another mineral possessed of very different properties.

Granatite is found in Galicia in Spain, and Britanny in France. It is always crystallized in a very peculiar form; two six sided prisms intersect each other, either at right angles or obliquely ‡. Hence the name *croisette*, by which it was known in France and Spain *. Mr Hauy has proved, in a very ingenious manner, that the primitive form of the granatite is a rectangular prism, whose bases are rhombs, with angles of 129½° and 50½°; and that the height of the prism is to the greater diagonal of a rhomb as 1 to 6; and that its integrant molecules are triangular prisms, similar to what would be obtained by cutting the primitive crystal in two, by a plane passing vertically through the shorter diagonal of the rhomboidal base. From this structure he has demonstrated the law of the formation of the cruciform varieties *. The colour of granatite is greyish or reddish brown.

‡ Fig. 10.
* Romé de Lisle, ii. 435.

Simple Stones.

* Ann. de Chim. vi. 142.

According to the analysis of Vauquelin, it is composed of

95.95 †

† Ibid xxx. 100.

GENUS VI. 2. SAL.

SPECIES 4. Tourmaline (z).

48 G. VI. 2. Sal. Tourmaline.

This stone was first made known in Europe by specimens brought from Ceylon; but it is now found frequently forming a part of the composition of mountains. It is either in amorphous pieces, or crystallized in three or nine sided prisms, with four sided summits.

Its texture is foliated: Its fracture conchoidal. Internal lustre 2 to 3. Transparency 3 to 4; sometimes only 2 (A). Causes only single refraction *. Hardness 9 to 11. Sp. gr. 3.05 to 3.155. Colour brown, often so dark that the stone appears black; the brown has also sometimes a tint of green, blue, red, or yellow.

* Hauy, Jour. de Min. No xxviii. 265.

When heated to 200° Fahrenheit, it becomes electric; one of the summits of the crystal negatively, the other positively †. It reddens when heated; and is fusible *per se* with intumescence into a white or grey enamel.

† Æpinus.

A specimen of the tourmaline of Ceylon, analysed by Vauquelin, was composed of

40 silica,
39 alumina,
12 oxyd of iron,
4 lime,
2.5 oxyd of manganese,

—————

97.5 ‡.

‡ Ann. de Chim. xxx. 105.

SPECIES 5. Argentine felspar §.

49 Argentine felspar.

§ Kirwan, i. 327.

This stone was discovered by Mr Dodun in the black mountains of Languedoc. It is either amorphous, or crystallized in rhomboidal tables, or six or eight sided prisms. Its texture is foliated. Fragments rectangular. Laminæ inflexible. Internal lustre 4. Transparency 2. Colour white; two opposite faces of the crystals are silver white, two others dead white. Hardness of the silvery laminæ 6, of the rest 9. Brittle. Sp. gr. 2.5. When the flame of the blow-pipe is directed against the edges of the crystal (stuck upon glass), it easily melts into a clear compact glass; but when the flame is directed against the faces, they preserve their lustre, and the edges alone slowly melt.

According to the analysis of Dodun, it is composed of

46 silica,
36 alumina,
16 oxyd of iron,

—

98

When this stone is exposed to the atmosphere, it is apt

Earths and Stones.

apt to decay: Its ſurface becomes irideſcent, and at laſt changes to ochre yellow: Its ſpecific gravity is 2.3 or 2.212; and when breathed upon, it gives out an earthy ſmell.

50 Mica.

SPECIES 6. Mica ||.

|| Kirw. i. 2.0—Gmelin, Nov. Com. Petropol. xii. 549.

This ſtone forms an eſſential part of many mountains, and has been long known under the names of *glacies mariæ* and *Muſcovy glaſs*. It conſiſts of a great number of thin laminæ adhering to each other, ſometimes of a very large ſize. Specimens have been found in Siberia nearly 2½ yards ſquare (B).

It is ſometimes cryſtallized: Its primitive form is a rectangular priſm, whoſe baſes are rhombs, with angles of 120° and 60° †: Its integrant molecule has the ſame form. Sometimes it occurs in rectangular priſms, whoſe baſes alſo are rectangles, and ſometimes alſo in ſhort fixſided priſms †; but it is much more frequently in plates or ſcales of no determinate figure or ſize *.

† Fig. 11.

† Fig. 12.

* Hauy, Jour. de Min. N° xxviii. 296.

Its texture is foliated. Its fragments flat. The lamellæ flexible, and ſomewhat elaſtic. Luſtre metallic, from 3 to 4. Tranſparency of the laminæ 3 or 4, ſometimes only 2 (C). Hardneſs 6. Very tough. Often abſorbs water. Sp. gr. from 2.6546 to 2.9342. Feels ſmooth, but not greaſy. Powder feels greaſy. Colour, when pureſt, ſilver white or grey; but it occurs alſo yellow, greeniſh, reddiſh, brown, and black. Mica is fuſible by the blow-pipe into a white, grey, green, or black, enamel; and this laſt is attracted by the magnet (D). Spaniſh wax rubbed by it becomes negatively electric *.

* Ibid.

A ſpecimen of mica, analyſed by Vauquelin, contained

50.00 ſilica,
35.00 alumina,
7.00 oxyd of iron,
1.35 magneſia,
1.33 lime,

94.68 †.

† Ibid. 302.

Mica has long been employed as a ſubſtitute for glaſs. A great quantity of it is ſaid to be uſed in the Ruſſian marine for panes to the cabin windows of ſhips; it is preferred, becauſe it is not ſo liable as glaſs to be broken by the agitation of the ſhip.

51 Talc.

SPECIES 7. Talc ‡.

‡ Kirw. i. 150.—Pott. Mem. Berl. 1746, p. 65.

This ſtone has a very ſtrong reſemblance to mica, and was long conſidered as a mere variety of that mineral. It occurs ſometimes in ſmall looſe ſcales, and ſometimes in an indurated form; but it has not hitherto been found cryſtallized.

Its texture is foliated. The lamellæ are flexible, but not elaſtic. Its luſtre is from 2 to 4. Tranſparency from 2 to 4. Hardneſs 4 to 6. Sp. gr. when indurated, from 2.7 to 2.8. Feels greaſy. Colour moſt commonly whitiſh or greeniſh. Spaniſh wax rubbed with it becomes *poſitively* electric §.

§ Hauy, Jour. de Min. N° xxviii. 291.

Variety 1. Scaly talc.
Talcite of Kirwan.

This variety occurs under the form of ſmall ſcales, ſcarcely cohering. Luſtre 3 to 4. Very light. Adheres to the fingers. When rubbed upon the ſkin, it gives it a gloſs. Colour white, with a ſhade of red or green; ſometimes leek green.

Simple Stones.

Variety 2. Common talc.
Venetian talc.

This variety often occurs in oblong nodules. Luſtre, nearly metallic, 4. Tranſparency 2 to 3; when very thin 4. Hardneſs 4 to 5. Colour white, with a ſhade of green or red; or apple green, verging towards ſilver white. By tranſmitted light green.

Variety 3. Shiſtoſe talc.

Its ſtructure is ſlaty. Fracture hackly and long ſplintery. Eaſily crumbles when rubbed in the fracture. External luſtre 2 to 3; internal, 1; but ſometimes, in certain poſitions, 3. Colour grey, with a ſhade of white, green or blue. Becomes white and ſcaly when expoſed to the air.

A ſpecimen of *common talc*, analyſed by Mr Chenevix, contained

48.0 ſilica,
37.0 alumina,
6.0 oxyd of iron,
1.5 magneſia,
1.5 lime,
5.0 water,

SPECIES 10. Refplendent Hornblende.

54 Refplendent hornblende.

There are two minerals which Werner confiders as varieties of hornblende, and Mr Kirwan as conftituting a diftinct fpecies. Thefe, till future analyfes decide the point, we fhall place here under the name of refplendent hornblende, the name given them by Mr Kirwan; and we fhall defcribe them feparately.

Variety 1. Labradore hornblende.

Texture, curved foliated. Luftre, in fome pofitions, 2; in others metallic, and from 3 to 4. Opaque. Hardnefs 8 to 9. Sp. gr. from 3.35 to 3.434. Colour, in moft pofitions, greyifh black; in others, it reflects a ftrong iron grey, fometimes mixed with copper red.

Variety 2. Shiller fpar *.

Texture foliated. Luftre metallic, 4. Tranfparency, in thin pieces, 1. Hardnefs 8 to 9. Sp. gr. 2.882. Colour, green, often with a fhade of yellow: alfo golden yellow. In fome pofitions it reflects white, grey, or yellow. At 141 Wedgewood, hardened into a porcelain mafs. A fpecimen, analyzed by Gmelin, was compofed of

43.7 filica,
17.9 alumina,
13.7 iron,
21.2 magnefia.

96.5 †

* Kirwan, i. 211

† Per Schr. Berl. 9 Band. p. 92.

It has been found in the Hartz, ftuck in a ferpentine rock.

SPECIES 11. Obfidian ‖.

Iceland agate.

55 Obfidian.

‖ Kirwan i. 264

This ftone is found either in detached maffes, or forming a part of the rocks which compofe many mountains. It is ufually invefted with a grey or opaque cruft. Its fracture is conchoidal. Its internal luftre 3. Tranfparency 1. Hardnefs 10. Sp. gr. 2.348. Colour black or greyifh black; when in very thin pieces, green. It melts into an opaque grey mafs. According to Bergman, it is compofed of

69 filica,
22 alumina,
9 iron.

100 §.

§ Bergm. iii. 204

SPECIES 12. Petrilite *.

Cubic felfpar.

56 Petrilite.

* Kirw. i. 325.

This ftone is found in the mafs of mountains. It is amorphous. Texture foliated. Fracture fplintery. Fragments cubic, or inclining to that form; their faces unpolifhed. Luftre 2. Tranfparency partly 2, partly 1. Hardnefs 9. Sp. gr. 3.081. Colour reddifh brown. Does not melt at 160 Wedgewood.

SPECIES 13. Felfite †.

Compact felfpar.

57 Felfite.

This ftone alfo forms a part of many mountains, and is amorphous. Texture fomewhat foliated. Fracture uneven, approaching to the fplintery. Luftre 1. Tranfparency fcarce 1. Hardnefs 9. Colour azure blue, and fometimes brown and green. Streak white. Before the blow-pipe, whitens and becomes rifty; but is infufible *per fe*.

Simple

GENUS VII. SAP.

58 G. VII. SAP. Felfpar.

SPECIES 1. Felfpar ‡.

‡ Kirw. i. 316. and Jour. de Phyf. paffim.

This ftone forms the principal part of many of the higheft mountains. It is commonly cryftallized. Its primitive form, according to De Lifle, is a rectangular prifm, whofe bafes are rhombs, with angles of 65° and 115° †. Sometimes the edges of the prifm are wanting, and faces in their place; and fometimes this is the cafe alfo with the acute angles of the rhomb. For a defcription and figure of thefe, and other varieties, we refer the reader to *Rome de Lifle* *, *Mr Hauy* †, and *Mr Pini* ‡.

† Fig. 13. and 14.

* Cryftall. ii. 461.

† Mem. Par. 1784, p. 273.

‡ Sur de Nouvelle Cryftallifation, &c. 8.

Its texture is foliated. Its crofs fracture uneven. Fragments rhomboidal, and commonly fmooth and polifhed on four fides. Luftre of the polifhed faces often 3. Tranfparency from 3 to 1. Hardnefs 9 to 10. Sp. gr. from 2.437 to 2.7. Gives a peculiar odour when rubbed. It is made electric with great difficulty by friction. Fufible *per fe* into a more or lefs tranfparent glafs. When cryftallized, it decrepitates before the blow-pipe.

Variety 1. Pure Felfpar.

Moon ftone—Adularia.

This is the pureft felfpar hitherto found. It occurs in Ceylon and Switzerland; and was firft mentioned by Mr Sage. Luftre nearly 3. Tranfparency 2 to 3. Hardnefs 10. Sp. gr. 2.559. Colour white; fometimes with a fhade of yellow, green, or red. Its furface is fometimes iridefcent.

Variety 2. Common Felfpar.

Luftre of the crofs fracture 0; of the fracture, in the direction of the laminæ, from 3 to 1. Tranfparency 2 to 1. Colour moft commonly flefh red; but often bluifh grey, yellowifh white, milk white, brownifh yellow; and fometimes blue, olive green, and even black.

Variety 3. Labradore felfpar.

This variety was difcovered on the coaft of Labradore by Mr Wolfe; and fince that time it has been found in Europe. Luftre 2 to 3. Tranfparency from 1 to 3. Sp. gr. from 2.67 to 2.6925. Colour grey. In certain pofitions, fpots of it reflect a blue, purple, red, or green colour.

Variety 4. Continuous felfpar.

This variety moft probably belongs to a different fpecies; but as it has not hitherto been analyfed, we did not think ourfelves at liberty to alter its place.

It is found in large maffes. Texture earthy. Fracture uneven, fometimes fplintery. Luftre 0. Tranfparency 1. Hardnefs 10. Sp. gr. 2.609. Colour reddifh grey, reddifh yellow, flefh red.

A fpecimen of green felfpar from Siberia, analyfed by Vauquelin, contained

62.83 filica,
17.02 alumina,
16.00 potafs,
3.00 lime,
1.00 oxyd of iron.

99.85 ‖

‖ Ann. de Chim. xxx

Earths and Stones.

SPECIES 2. Lepidolite (F).

Lilalite.

59 Lepidolite.

This stone appears to have been first observed by the Abbé Poda, and to have been first described by De Born §. Hitherto it has only been found in Moravia in Germany, and Sudermania in Sweden *. There it is mixed with granite in large amorphous masses. It is composed of thin plates, easily separated, and not unlike those of mica †. Lustre, pearly 3. Transparency between 1 and 2. Hardness 4 to 5. Not easily pulverised ‡. Sp. gr. from 2.816 ‖ to 2.8549 ¶. Colour of the mass, violet blue; of the thin plates, silvery white. Powder white, with a tint of red §. Before the blowpipe, it froths, and melts easily into a white semitransparent enamel, full of bubbles. Dissolves in borax with effervescence, and communicates no colour to it *. Effervesces slightly with soda, and melts into a mass spotted with red. With microcosmic salt, it gives a pearl coloured globule †.

This stone was first called lilalite from its colour, that of the *lily*. Klaproth, who discovered its component parts, gave it the name of *lepidolite* (G).

It is composed of

53 silica,
20 alumina,
18 potash,
5 fluat of lime,
3 oxyd of manganese,
1 oxyd of iron.

100 ‡

* *Ibid.*
† *Klaproth*, *Ann de Chim.* xxii. 87.
‡ *Vauquelin*, *Ann. de Chim.* xxx. 105.

SPECIES 3. Leucite ‖.

Vesuvian of Kirwan—*White garnet* of Vesuvius.

60 Leucite.

This stone is usually found in volcanic productions, and is very abundant in the neighbourhood of Vesuvius. It is always crystallized. The primitive form of its crystals is either a cube or a rhomboidal dodecahedron, and its integrant molecules are tetrahedrons; but the varieties hitherto observed are all polyhedrons: The most common has a spheroidal figure, and is bounded by 24 equal and similar trapeziods †; sometimes the faces are 12, 18, 36, 54, and triangular, pentagonal, &c. For a description and figure of several of these, we refer the reader to Mr Hauy ‖. The crystals vary from the size of a pin head to that of an inch.

The texture of the leucite is foliated. Its fracture somewhat conchoidal. Lustre 3; when in a state of decomposition 0. Transparency 3 to 2; when decomposing 0. Hardness 8 to 10; when decomposing 5 to 6. Sp. gr. 2.4648. Colour white, or greyish white (H). Its powder causes syrup of violets to assume a green colour *.

It is composed, as Klaproth has shewn, of

54 silica,
23 alumina,
22 potash.

99 (I)

‖ *Kirw.* i. 285.
† Fig. 15.
‖ *Jour de Min.* No xxvii. 185.
* *Vauquelin*, *Jour. de Min.* No xxxix. 165.

It was by analysing this stone that Klaproth discovered the presence of potash in the mineral kingdom; which is not the least important of the numerous discoveries of that accurate and illustrious chemist.

Simple Stones.

Leucite is found sometimes in rocks which have never been exposed to volcanic fire; and Mr Dolomieu has rendered it probable, from the situations in which it is found, that the leucite of volcanoes has not been formed by volcanic fire, but that it existed previously in the rocks upon which the volcanoes have acted, and that it was thrown out unaltered in fragments of these rocks §.

§ *Jour de Min.* No xxxix. 177.

GENUS VIII. SAG.

SPECIES 1. Emerald (K).

61 Gen. VIII sag. Emerald.

This stone has hitherto been only found crystallized. The primitive form of its crystals is a regular six-sided prism; and the form of its integrant molecules is a triangular prism, whose sides are squares, and bases equilateral triangles *. The most common variety of its crystals is the regular six-sided prism, sometimes with the edges of the prism, or of the bases, or the solid angles, or both wanting ‡, and small faces in their place †. The sides of the prism are generally channelled.

Its texture is foliated. Its fracture conchoidal. Lustre usually from 3 to 4. Transparency from 2 to 4. Causes a double refraction. Hardness 12. Sp. gr. 2.65 to 2.775. Colour green. Becomes electric by friction, but not by heat. Its powder does not phosphoresce when thrown on a hot iron †. At 150° Wedgewood it melts into an opaque coloured mass. According to Dolomieu, it is fusible *per se* by the blow-pipe ‡.

This mineral was formerly subdivided into two distinct species, the *emerald*, and *beryl* or *aqua marina*. Hauy demonstrated, that the emerald and beryl corresponded exactly in their structure and properties, and Vauquelin found that they were composed of the same ingredients, henceforth, therefore, they must be considered as varieties of the same species.

The variety formerly called *emerald* varies in colour from the pale to the perfect green. When heated to 120° Wedgewood, it becomes *blue*, but recovers its colour when cold. A specimen, analysed by Vauquelin, was composed of

64.60 silica,
14.00 alumina,
13.00 glucina,
3.50 oxyd of chromum,
2.56 lime,
2.00 moisture or other volatile ingredient.

99.66 ‖

The *beryl* is of a greyish green colour, and sometimes blue, yellow, and even white: sometimes different colours appear in the same stone §. It is found in Ceylon, different parts of India, Brazil, and especially in Siberia and Tartary, where its crystals are sometimes a foot long ¶.

It was by analyfing this ftone that Vauquelin difcovered the earth which he called *glucina*.

62 G. IX. SAB. Staurolite.

GENUS IX. SAB.

SPECIES 1. Staurolite *.

* Kirw. i. 282.

Andreolite of Lametherie and Hauy—*Hyacinthe blanche cruciforme*, var. 0. of Romé de Lifle.

This ftone has been found at Andreafberg in the Hartz. It is cryftallized, and the form of its cryftals has induced mineralogifts to give it the name of *crofsftone*. Its cryftals † are two four-fided flattened prifms, terminated by four fided pyramids, interfecting each other at right angles: the plane of interfection paffing longitudinally through the prifms (L).

† Fig. 17.

Its texture is foliated. Its luftre waxy, 2. Tranfparency from 1 to 3. Hardnefs 9. Brittle. Sp. gr. 2.355 to 2.361. Colour milk white. When heated flowly, it lofes 0.15 or 0.16 parts of its weight, and falls into powder. It effervefces with borax and microcofmic falt, and is reduced to a greenifh opaque mafs. With foda it melts into a frothy white enamel. When its powder is thrown on a hot coal, it emits a greenifh yellow light †.

† Hauy, Jour. de Min. N° xxviii. 280.

A fpecimen analyfed by Weftrum was compofed of

44	filica,
20	alumina,
20	barytes,
16	water.
100	

Klaproth found the fame ingredients, and nearly in the fame proportions ‡.

‡ Beitrage, ii. 80.

A variety of ftaurolite has been found only once, which has the following peculiarities.

Its luftre is pearly, 2. Sp. gr. 2.361. Colour brownifh grey. With foda it melts into a purplifh and yellowifh frothy enamel. It is compofed, according to Weftrum, of

47.5	filica,
12.0	alumina,
20.0	barytes,
16.0	water,
4.5	oxyds of iron and manganefe.

GENUS

(L) See *Gillot*, *Jour. de Phyf.* 1792, p. 1 and 2.

(M) Hence probably the name *hyalite*, which was impofed by Werner from ὕαλος, *glafs*, and λίθος, *a ftone*.

Earths and Stones.

GENUS X. 3. SAWL.

SPECIES 4. Zeolite (N).

66 G. X. 3. SAWL. Zeolite. This stone was first described by Cronstedt in the Stockholm Transactions for 1756. It is found sometimes amorphous and sometimes crystallized. The primitive form of its crystals is a rectangular prism, whose bases are squares. The most common variety is a long four sided prism, terminated by low four sided pyramids*.

Its texture is striated or fibrous. Its lustre is silky, from 3 to 1. Transparency from 2 to 4; sometimes 1. Hardness 6 to 8; sometimes only 4. Absorbs water. Sp. gr. 2.07 to 2.3. Colour white, often with a shade of red or yellow; sometimes brick red, green, blue. When heated, it becomes electric like the tourmaline†. Before the blow-pipe it froths (O), emits a phosphorescent light, and melts into a white semitransparent enamel, too soft to cut glass, and soluble in acids. In acids it dissolves slowly and partially without effervescence; and at last, unless the quantity of liquid be too great, it is converted into a jelly.

A specimen of zeolite (P), analysed by Vauquelin, contained

53.00	silica,
27.00	alumina,
9.46	lime,
10.00	water.
99.46‡.	

SPECIES 5. Stilbite.

67 Stilbite. This stone was first formed into a distinct species by Mr Hauy. Formerly it was considered as a variety of zeolite.

The primitive form of its crystals is a rectangular prism, whose bases are rectangles. It crystallizes sometimes in dodecahedrons, consisting of a four-sided prism with hexagonal faces, terminated by four-sided summits, whose faces are oblique parallelograms; sometimes in six-sided prisms, two of whose solid angles are wanting, and a small triangular face in their place*.

Its texture is foliated. The laminæ are easily separated from each other; and are somewhat flexible. Lustre pearly, 2 or 3 (Q). Hardness inferior to that of zeolite, which scratches stilbite. Brittle. Sp. gr. 2.500†. Colour pearl white. Powder bright white, sometimes with a shade of red. This powder, when exposed to the air, cakes and adheres as if it had absorbed water. It causes syrup of violets to assume a green colour. When stilbite is heated in a porcelain crucible, it swells up and assumes the colour and semitransparency of baked porcelain. By this process it loses 0.185 of its weight. Before the blow-pipe it froths like borax, and then melts into an opaque white coloured enamel §.

According to the analysis of Vauquelin, it is composed of

52.0	silica,
17.5	alumina,
9.0	lime,
18.5	water.
97.0‖	

SPECIES 6. Analcime.

68 Analcime. This stone, which was discovered by Mr Dolomieu, is found crystallized in the cavities of lava. It was first made a distinct species by Mr Hauy. Mineralogists had formerly confounded it with zeolite.

The primitive form of its crystals is a cube. It is sometimes found crystallized in cubes, whose solid angles are wanting, and three small triangular faces in place of each; sometimes in polyhedrons with 24 faces. It is usually somewhat transparent. Hardness about 8; scratches glass slightly. Sp. gr. above 2. When rubbed, it acquires only a small degree of electricity, and with difficulty (R). Before the blow-pipe it melts without frothing, into a white semitransparent glass*.

GENUS X. 4. SLA.

SPECIES 7. Lazulite†.

69 G. X. 4. SLA. Lazulite. This stone, which is found chiefly in the northern parts of Asia, has been long known to mineralogists by the name of *lapis lazuli*. This term has been contracted into *lazulite* by Mr Hauy; an alteration which was certainly proper, and which therefore we have adopted.

Lazulite is always amorphous. Its texture is earthy. Its fracture uneven. Lustre 0. Opaque, or nearly so. Hardness 8 to 9. Sp. gr. 2.76 to 2.945‡. Colour blue (S); often spotted white from specks of quartz, and yellow from particles of pyrites.

It retains its colour at 100° Wedgewood; in a higher heat it intumesces, and melts into a yellowish black mass. With acids it effervesces a little, and if previously calcined, forms with them a jelly.

Margraff published an analysis of lazulite in the Berlin Memoirs for 1758. His analysis has since been confirmed by Klaproth, who found a specimen of it to contain

46.0	silica,
14.5	alumina,
28.0	carbonat of lime,
6.5	sulphat of lime,
3.0	oxyd of iron,
2.0	water.

Earths and Stones.

crystals is a dodecahedron whose sides are rhombs, with angles of 70° 31' 44", and 109° 28' 16". The inclination of the rhombs to each other is 120°. This dodecahedron may be considered as a four-sided prism, terminated by four-sided pyramids *. It is divisible into four parallelopipeds, whose sides are rhombs; and each of these may be divided into four tetrahedrons, whose sides are isosceles triangles, equal and similar to either of the halves into which the rhomboidal faces of the dodecahedron are divided by their shorter diagonal. The integrant molecules of garnet are similar tetrahedrons †. Sometimes the edges of the dodecahedron are wanting, and small faces in their place; and sometimes garnet is crystallized in polyhedrons, having 24 trapezoidal faces. For a description and figure of these, and other varieties of garnet, we refer to *Romé de Lisle* and *Hauy* ‡.

Simple Stones.

¶ Beiträge, ii. 21.

SPECIES 2. Thumerstone *.

Yanolite of Lametherie—*Axinite* of Hauy.

71 Thumerstone.

This stone was first described by Mr Schreber, who found it near Balme d'Auris in Dauphiné, and gave it the name of *shorl violet* †. It was afterwards found near Thum in Saxony, in consequence of which Werner called it *thumerstone*.

* Kirw. i. 273.—Pel. Jour. de Phys. xxvi 66.
† De Lisle, ii. 353.

It is sometimes amorphous; but more commonly crystallized. The primitive form of its crystals is a rectangular prism, whose bases are parallelograms with angles of 101° 32' and 78° 28' ‡. The most usual variety is a flat rhomboidal parallelopiped, with two of its opposite edges wanting, and a small face in place of each §. The faces of the parallelopiped are generally streaked longitudinally.

‡ Hauy, Jour. de Min. N° xxviii 264.
§ Fig 21.
§ De Lisle, ibid.

The texture of thumerstone is foliated. Its fracture conchoidal. Lustre 2. Transparency, when crystallized, 3 to 4; when amorphous, 2 to 1. Causes simple refraction ||. Hardness 10 to 9. Sp gr. 3.2956. Colour clove brown; sometimes inclining to red, green, grey, violet, or black. Before the blow-pipe it froths like zeolite, and melts into a hard black enamel. With borax it exhibits the same phenomena, or even when the stone is simply heated at the end of a pincer ¶.

|| Hauy, ibid.
¶ Vauquel Jour. de Min. N° xxiii. 1.

A specimen of thumerstone, analysed by Klaproth, contained

52.7	silica,
25.6	alumina,
9.4	lime,
9.6	oxyd of iron with a trace of manganese.
97.3 *	

* Beiträge, ii. 126.

A specimen, analysed by Vauquelin, contained

44	silica,
18	alumina,
19	lime,
14	oxyd of iron,
4	oxyd of manganese.
99 †	

† Jour. de Min. ibid.

SPECIES 3. Prehnite (y).

72 Prehnite.

Though this stone had been mentioned by Sage †, Romé de Lisle *, and other mineralogists, Werner was the first who properly distinguished it from other minerals, and made it a distinct species. The specimen which he examined was brought from the Cape of Good Hope by Colonel Prehn; hence the name *prehnite*, by which he distinguished it. It was found near Dumbarton by Mr Grotche †; and since that time it has been observed in other parts of Scotland.

† Miner. i. 232.
* Crystallog. ii. 275.
† Ann. de Chim. i. 213.

It

(u) This seems to be the *carbunculus* [illegible] of Theophrastus, and the *carbunculus garamanticus* of other ancient writers. See *Hill's Theophrastus*, [illegible] p. 74 and 77.

(x) Hence, according to many, the name *garnet* (in Latin *granatus*), from the resemblance of the stone in colour to the blossoms of the pomegranate.

(y) *Kirw.* I. 274.—*Hassenfratz, Jour. de Phys.* XXXII. 81.—*Sage, ibid.* XXXIV. 446.—*Klaproth, Beob. der Berlin*, 2 *Band.* 211. And *Ann. de Chim.* I. 201.

Earth and Stones.

It is both amorphous and crystallized. The crystals are in groups, and confused: they seem to be four-sided prisms with dihedral summits ‡. Sometimes they are irregular six sided plates, and sometimes flat rhomboidal parallelopipeds.

‡ Hauy, Jour. de Min Nº xxviii. 277.

Its texture is foliated. Fracture uneven. Internal lustre pearly, scarcely 2. Transparency 3 to 2. Hardness 9 to 10. Brittle. Sp. gr. 2.6969 ||. Colour apple green, or greenish grey. Before the blow-pipe it froths more violently than zeolite, and melts into a brown enamel. A specimen of prehnite, analysed by Klaproth, was composed of

|| Hauy, ibid.

43.83	silica,

SPECIES 4. Thallite.

73 Thallite

Green shorl of Dauphiné of De Lisle*—*Delphinite* of Saussure.

* Crystallog. ii. 401.

This stone is found in the fissures of mountains; and hitherto only in Dauphiné and on Chamouni in the Alps.

It is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals is a rectangular prism, whose bases are rhombs with angles of 114° 37', and 65° 23' †. The most usual variety is an elongated four-sided prism (often flattened), terminated by four-sided incomplete pyramids §; sometimes it occurs in regular six-sided prisms ‡. The crystals are often very slender.

† Hauy, Jour. de Min Nº xxviii 271. § Fig. 12. Romé de Lisle, ibid. and Hauy, Jour de Min Nº xxx 415.

Its texture appears fibrous. Lustre inconsiderable. Transparency 2 to 3, sometimes 4; sometimes nearly opaque. Causes single refraction. Hardness 9 to 10. Brittle. Sp. gr. 3.4529 to 3.46. Colour dark green (z). Powder white or yellowish green, and feels dry. It does not become electric by heat. Before the blow-pipe, froths and melts into a black slag. With borax melts into a green bead ||.

|| Hauy, and Descotils, ibid.

A specimen of thallite, analysed by Mr Descotils, contained

37	silica,
27	alumina,
17	oxyd of iron,
14	lime,
1.5	oxyd of manganese.
96.5 §	

§ Ibid Nº xxx. 420.

GENUS XII. ALUMINA-MAGNESIA.

SPECIES 1. Cyanite*.

Sappare of Saussure.

Sappare Stones.

74 G. XII Alumina-Magnesia. Cyanite.

This stone was first described by Mr Saussure, the son, who gave it the name of *sappare* †. It is commonly found in granite rocks. The primitive form of its crystals is a four sided oblique prism, whose sides are inclined at an angle of 103°. The base forms with one side of the prism an angle of 103°; with another, an angle of 77°. It is sometimes crystallized in six sided prisms ‡.

* Kirw. i. 209.—Sage, Jour. de Phys. xxxv. 39.

† Jour de Phys. xxxiv. 213.

Its texture is foliated. Laminæ long. Fragments long, splintery. Lustre pearly, 2 to 3. Transparency of the laminæ 3. Causes single refraction ||. Hardness 6 to 9. Brittle. Sp. gr. from 3.092 to 3.622 ‡. Feels somewhat greasy. Colour milk white, with shades of sky or prussian blue (A); sometimes bluish grey; sometimes partly bluish grey, partly yellowish or greenish grey.

‡ Hauy, Jour de Min. Nº xxviii. 282.

|| Hauy, ibid.

‡ Kirwan.

Before the blow pipe it becomes almost perfectly white; but does not melt. According to the analysis of Saussure, it is composed of

66.92	alumina,
13.25	magnesia,
12.81	silica,
5.48	iron,
1.71	lime.
100.17 ¶	

¶ Jour de Phys ibid.

Cyanite has also been analysed by Struvius and Hermann, who agree with Saussure as to the ingredients; but differ widely from him and one another as to the proportions.

* [illegible] † [illegible] 179 ‡ Ibid.

GENUS XII. 2. MSA.

SPECIES 2. Serpentine (B).

75 G. XII. [illegible]

This stone is found in amorphous masses. Its fracture is splintery. Lustre 0. Opaque. Hardness 6 to 7. Sp. gr. 2.2645 to 2.709. Feels rather soft, almost greasy. Generally emits an earthy smell when breathed upon. Its colours are various shades of green, yellow, red, grey, brown, blue: commonly one or two colours form the ground, and one or more appear in spots or veins (C).

Before the blow pipe it hardens and does not melt.

A specimen of serpentine, analysed by Mr Chenevix, contained

34.5	magnesia,
28.0	silica,
23.0	alumina,
4.5	oxyd of iron,
0.5	lime,
10.5	water.
101.0*	

GENUS [illegible]

(z) Hence the name *thallite* given it by Lametheric, from θαλλος, *a green leaf*.

(A) Hence the name *cyanite*, imposed by Werner.

(B) *Kirw.* I. 156.—*Margraf, Mem. Berlin*, 1759, p. 3.—*Bayen, Jour. de Phys.* XIII. 46.—*M*[illegible] *Annals*, 1789, II. 416.

(C) Hence the name *serpentine*, given to the stone from a supposed resemblance in colours to the skin of a serpent.

Earths and Stones. | Simple Stones.

76
G. XIII. MSAI. Potſtone.
† Kirw. i. 155.

GENUS XIII. MSAI.

SPECIES 1. Potſtone †.

This ſtone is found in neſts and beds, and is always amorphous. Its ſtructure is often ſlaty. Texture undulatingly foliated. Luſtre from 1 to 3. Tranſparency from 1 to 0; ſometimes 2. Hardneſs 4 to 6. Brittle. Sp. gr. from 2.8531 to 3.023. Feels greaſy. Sometimes abſorbs water. Colour grey with a ſhade of green, and ſometimes of red or yellow; ſometimes leek green; ſometimes ſpeckled with red.

Potſtone is not much affected by fire; and has therefore been made into utenſils for boiling water; hence its name.

According to Wiegleb, the potſtone of Como contains
38 magneſia,
38 ſilica,
7 alumina,
5 iron,
1 carbonat of lime,
1 fluoric acid.
———
90

77
Chlorite.
* Kirw. i. 147

SPECIES 2. Chlorite*.

This mineral enters as an ingredient into different mountains. It is ſometimes amorphous, and ſometimes cryſtallized in oblong, four ſided, acuminated cryſtals.

Its texture is foliated. Its luſtre from 0 to 2. Opaque. Hardneſs from 4 to 6; ſometimes in looſe ſcales. Colour green.

Variety 1. Farinaceous chlorite.

Compoſed of ſcales ſcarcely cohering, either heaped together, or inveſting other ſtones. Feels greaſy. Gives an earthy ſmell when breathed on. Difficult to pulveriſe. Colour graſs green; ſometimes greeniſh brown; ſometimes dark green, inclining to black. Streak white. When the powder of chlorite is expoſed to the blowpipe it becomes brown. Before the blow pipe, farinaceous chlorite froths and melts into a dark brown glaſs; with borax it forms a greeniſh brown glaſs*:

* [illegible] melin, [illegible] Nov. N° xxxix. 167.

Variety 2. Indurated chlorite.

This variety is cryſtallized. Luſtre 1. Hardneſs 6. Feel meage. Colour dark green, almoſt black. Streak mountain green.

Variety 3. Slaty chlorite.

Structure ſlaty. Fragments flatted. Internal luſtre 1 to 2. Hardneſs 5. Colour greeniſh grey, or dark green inclining to black. Streak mountain green.

A ſpecimen of the firſt variety, analyſed by Vauquelin, contained
43.3 oxyd of iron,
26.0 ſilica,
15.5 alumina,
8.0 magneſia,
2.0 muriat of potaſs,
4.0 water.
———
98.8 †

† Ann. de Chim. xxx. 106.

A ſpecimen of the ſame variety yielded Mr Høpner
12.92 oxyd of iron,
37.50 ſilica,
4.17 alumina,
43.75 magneſia,
1.66 lime.
———
100.0 ‡

‡ Sauſſure's Voyages, ii. 133.

A ſpecimen of the ſecond variety, analyſed by the ſame chemiſt, contained
10.15 oxyd of iron,
41.15 ſilica,
6.13 alumina,
39.47 magneſia,
1.50 lime,
1.50 air and water.
———
99.9 §.

§ Crell's Annals, 1790, p. 56.

On the ſuppoſition that theſe analyſes are accurate, the enormous difference between them is a demonſtration that chlorite is not a chemical combination, but a mechanical mixture.

78
G. XIV. SLAM. Siliceous ſpar.

GENUS XIV. SLAM.

SPECIES 1. Siliceous ſpar (D).

This ſtone has been found in Tranſylvania. It is cryſtallized in 4 or 6 ſided priſms, channelled tranſverſely, and generally heaped together. Its texture is fibrous. Its luſtre ſilky, 2. Its colours white, yellow, green, light blue. According to Bindheim, it contains
61.1 ſilica,
21.7 lime,
6.6 alumina,
5.0 magneſia,
1.3 oxyd of iron,
3.3 water.
———
99.0 *

79
G. XV. SAMLI. Argillite.
† Kirw. i. 234.

GENUS XV. SAMLI.

SPECIES 1. Argillite †.

Argillaceous ſchiſtus—Common ſlate.

This ſtone conſtitutes a part of many mountains.

Its ſtructure is ſlaty. Its texture foliated. Fracture ſplintery. Fragments often tabular. Luſtre moſt commonly ſilky, 2; ſometimes 0. Tranſparency from 0 to 1. Hardneſs from 5 to 8. Sp. gr. from 2.67 to 2.88. Does not adhere to the tongue. Gives a clear ſound when ſtruck. Often imbibes water. Streak white or grey. Colour moſt commonly grey, with a ſhade of blue, green, or black; ſometimes purpliſh, yellowiſh, mountain green, brown, bluiſh black; ſometimes ſtriped or ſpotted with a darker colour than the ground.

It is compoſed, according to Kirwan, of ſilica, alumina, magneſia, lime, oxyd of iron. In ſome varieties the

(D) Is this the *tremolite* of Lowitz from the lake Baikal in Siberia? If ſo, the name of the genus ought to be SLM; for he found it to contain no alumina. According to his analyſis, it was compoſed of
52 ſilica,
20 lime,
12 carbonat of lime,
12 magneſia,
———
96

The

Earths and Stones.

the lime is wanting. Several varieties contain a considerable quantity of carbonaceous matter.

Simple Stones.

Genus XVI. SLACMI.

80 G. XVI. SLACMI. Smaragdite.

SPECIES 1. Smaragdite.

This stone was called *smaragdite* by Mr Saussure, from some resemblance which it has to the emerald. Its texture is foliated. The laminæ are inflexible. Fracture even. Hardness 7. Colour in some cases fine green, in others it has the grey colour and metallic lustre of mica: it assumes all the shades of colour between these two extremes †.

According to the analysis of Vauquelin, it is composed of

50.0	silica,
13.0	lime,
11.0	alumina,
7.5	oxyd of chromum.
6.0	magnesia,
5.5	oxyd of iron,
1.5	oxyd of copper.

Genus XVII. SM.

81 G. XVII. SM. Kiffekil.

SPECIES 1. Kiffekil*.

Myrsen—Seafroth.

This mineral is dug up near Konie in Natolia, and is employed in forming the bowls of Turkish tobacco pipes. The sale of it supports a large monastery of dervises established near the place where it is dug. It is found in a large fissure six feet wide, in grey calcareous earth. The workmen assert, that it grows again in the fissure †, and puffs itself up like froth (E). This mineral, when fresh dug, is of the consistence of wax; it feels soft and greasy; its colour is yellow; its sp. gr. 1.600 ‡: when thrown on the fire it sweats, emits a fetid vapour, becomes hard, and perfectly white.

* Kirwan's Min. i. 144.

† Reignegg. Philos. Mag. iii. 63.

‡ Klaproth.

According to the analysis of Klaproth, it is composed of

50.50	silica,
17.25	magnesia,
25.00	water,
5.00	carbonic acid,
.50	lime.
98.25 §	

§ Beiträge, 172.

82 Steatites.

SPECIES 2. Steatites (F).

Though this mineral was noticed by the ancients, little attention was paid to it by mineralogists, till Mr Pott published his experiments on it in the Berlin Memoirs for 1747.

It is usually amorphous, but sometimes it is crystallized in six-sided prisms. Its texture is commonly earthy, but sometimes foliated. Lustre from 0 to 2. Transparency from 0 to 2. Hardness 4 to 7. Sp. gr. from 2.61 to 2.794 *. Feels greasy. Seldom adheres to the tongue. Colour usually white or grey; often with a tint of other colours; the foliated commonly green. Does not melt *per se* before the blow-pipe.

* Brisson.

Variety 1. Semi-indurated steatites.

Texture earthy. Fracture sometimes coarse splintery. Lustre 0. Transparency 0, or scarce 1. Hardness 4 to 5. Absorbs water. Takes a polish from the nail. Colour white, with a shade of grey, yellow, or green; sometimes pure white; sometimes it contains dendritical figures; and sometimes red veins.

Variety 2. Indurated steatites.

Fracture fine splintery, often mixed with imperfectly conchoidal. External lustre 2 to 1, internal 0. Transparency 2. Often has the feel of soap. Absorbs water. Colour yellowish or greenish grey; often veined or spotted with deep yellow or red.

Variety 3. Foliated or striated steatites.

The texture of this variety is usually foliated; sometimes striated. Fragments cubiform. Lustre 3. Transparency 2 to 1. Hardness 6 to 7. Colour leek green, passing into mountain green or sulphur yellow. Streak pale greenish grey. When heated to redness, it becomes grey; and at 147° Wedgewood, it forms a grey porous porcelain mass*.

* Kirwan, i. 155.

A specimen of steatites, analysed by Klaproth, contained

59.5	silica,
30.5	magnesia,
2.5	iron,
5.5	water,
98.0 †	

† Beiträge, ii. 179.

2.50	lime,
2.25	iron.
96.25 ‡	

‡ Ann de Chim xxvi 200.

Genus XVIII. MSI.

83 G. XVIII. MSI. Chrysolite.

SPECIES 1. Chrysolite (G).

Peridot of the French—*Topaz* of the ancients.

The name *chrysolite* was applied, without discrimination, to a great variety of stones, till Werner defined it accurately, and confined it to that stone which the French chemists distinguish by the appellation of *peridot*. This stone is the *topaz* of the ancients; their chrysolite is now called *topaz* §.

§ Plinii, lib. 37. c. 8.

Chrysolite is found sometimes in unequal fragments, and sometimes crystallized †. The primitive form of its crystals is a right angled parallelopiped ‡, whose length, breadth, and thickness, are as 5, $\sqrt{8}$, $\sqrt{5}$*.

† Fig. 13.

‡ Fig. 14.

* Hauy, Jour. de Min. N° xxviii. 251.

The texture of the chrysolite is foliated. Its fracture conchoidal. Its internal lustre from 2 to 4. Its transparency from 4 to 2. Causes double refraction. Hardness

The carbonat of lime was only mechanically interposed between the fibres of the stone. See *Pallas, Neu. Nord. Beiträge*, 6 *Band*, p. 146.

(E) Hence the name *kiff-kil*, or rather *keff-kelli*, "clay froth," or "light clay."

(F) *Kirw.* I. 151.—*Pott, Mem. Berlin*, 1747, p. 57.—*Wiegleb, Jour. de Phys.* XXIX. 60.—*Lavoisier, Mem. Par.* 1778, 433.

38.0 silica,
9.5 oxyd of iron.

99.0‡

‡ Ann de Chim ibid.

The second variety, according to the analysis of Klaproth, is composed of
37.58 magnesia,
50.00 silica,
11.75 oxyd of iron,
.21 lime.

99.54 §.

§ Beiträge, i. 112.

84 Jade.

SPECIES 2. Jade (H).

This stone was formerly called *lapis niphriticus*, and was much celebrated for its medical virtues. It is found in Egypt, China, America, and in the Siberian and Hungarian mountains. It is sometimes adhering to rocks, and sometimes in detached round pieces.

Its surface is smooth. Its fracture splintery. External lustre 0, or scarce 1; internal waxy, 1. Transparency from 2 to 1. Hardness 10. Not brittle. Sp. gr. from 2.95 to 2.9829; or, according to Saussure, to 3.389. Feels greasy. Looks as if it had imbibed oil. Colour dark leek green, or verging towards blue; in some prominencies inclining to greenish or bluish white. When heated it becomes more transparent and brittle, but is infusible *per se*. According to Hœpfner, it is composed of
47 silica,
38 carbonat of magnesia,
9 iron,
4 alumina,
2 carbonat of lime,

100

This is the stone which the inhabitants of New Zealand make into hatchets and other cutting instruments.

G. XIX. SML.

GENUS XIX. SML.

SPECIES 1. Asbestus (I).

This mineral was well known to the ancients. They even made a kind of cloth from one of the varieties, which was famous among them for its incombustibility. It is found abundantly in most mountainous countries, and no where more abundantly than in Scotland.

It is commonly amorphous. Its texture is fibrous. Its fragments often long splintery. Lustre from 0 to 2; sometimes 3, and then it is metallic. Transparency from 0 to 2. Hardness from 3 to 7. Sp. gr. from 2.7 to 0.6806. Absorbs water. Colour usually white or green. Fusible *per se* by the blow-pipe.

Variety 1. Common asbestus.

Lustre 2 to 1. Transparency 1. Hardness 6 to 7. Sp. gr. 2.577 to 2.7. Feels somewhat greasy. Colour leek green; sometimes olive or mountain green; sometimes greenish or yellowish grey. Streak grey. Powder grey.

Variety 2. Flexible asbestus.

Amiantus.

Composed of a bundle of threads slightly cohering. Fibres flexible. Lustre 1 to 2, sometimes 3. Transparency 1 to 2, sometimes 0. Hardness 3 to 4. Sp. gr. before it absorbs water, from 0.9088 to 2.3134; after absorbing water, from 1.5662 to 2.3803†. Feels greasy. Colour greyish or greenish white; sometimes yellowish or silvery white, olive or mountain green, pale flesh red, and mountain yellow.

† Brisson.

Variety 3. Elastic asbestus.

Mountain cork.

This variety has a strong resemblance to common cork. Its fibres are interwoven. Lustre commonly 0. Opaque. Hardness 4. Sp. gr. before absorbing water, from 0.6806 to 0.9933; after absorbing water, from 1.2492 to 1.3492. Feels meagre. Yields to the fingers like cork, and is somewhat elastic. Colour white; sometimes with a shade of red or yellow; sometimes yellow or brown.

A specimen of the first variety from Dalecarlia, analysed by Bergman, contained
63.9 silica,
16.0 carbonat of magnesia,
12.8 carbonat of lime,
6.0 oxyd of iron,
1.1 alumina.

99.8 *

A specimen of the second variety yielded to the same chemist
64.0 silica,
17.2 carbonat of magnesia,
13.9 carbonat of lime,
2.7 alumina,
2.2 oxyd of iron.

100.0 †

* Opusc. iv. 170.

A specimen of the third variety contained, according to the same analysis, 56.2 silica,
26.1 carbonat of magnesia,
12.7 carbonat of lime,
3.0 iron,
2.0 alumina.

100.0 ‡

† Opusc. iv.

SPECIES 2. Asbestinite (K)

86 Asbestinite. This stone is amorphous. Texture foliated or broad striated. Lustre silky, 3. Transparency 1 to 2. Hardness 5 to 6. Sp. gr. from 2.806 to 2.880. Colour white, with shades of red, yellow, green, or blue. At 150° Wedgewood it melts into a green glass.

87 G. XX. 1. SILM. Pyroxen.

GENUS XX. 1. SILM.

SPECIES 1. Pyroxen

This stone is found abundantly in lava and other volcanic productions (L). It is always crystallized. The primitive form of its crystals is an oblique angled prism, whose bases are rhombs with angles of 92° 18, and 37° 42′ ‡. It generally crystallizes in eight sided prisms, terminated by dihedral summits ||. Its texture is foliated. Hardness 9. Colour black; sometimes green. Powder greenish grey *. Commonly attracted by the magnet †. Scarcely fusible by the blow pipe ‡. With borax it melts into a yellowish glass, which appears red while it is hot §.

|| De Lisle, ... 98.
* Vauquelin, Gerber.
§ Lievre.
|| Vauquelin.

According to the analysis of Vauquelin, it is composed of

52.00	silica,
14.66	oxyd of iron,
13.20	lime,
10.00	magnesia,
3.33	alumina,
2.00	oxyd of manganese.
95.19 ||	

|| Jour. de Min. N° ... x. 172.

SPECIES 2. Asbestoid *.

88 Asbestoid. This stone has obtained its name from its similarity to common asbestus. It is amorphous. Its texture is foliated or striated. Its lustre common or glassy, from 2 to 3. Transparency from 0 to 1. Hardness 6 to 7. Sp. gr. from 3 to 3.31. Colour olive or leek green; when decomposing, brown. Before the blowpipe it melts *per se* into a brown globule. With borax it forms a violet coloured globule verging towards hyacinth †. According to the analysis of Mr Macquart, it is composed of

Simple Stones.

GENUS XX. 2. SMIL.

SPECIES 3. Shorlaceous actinolite (M).

89 G. XX. 2. SMIL. Shorlaceous actinolite. This stone crystallizes in four or six sided prisms, thicker at one end than the other; hence it has been called by the Germans *strahlstein*, " arrow-stone." The crystals sometimes adhere longitudinally. Fracture hackly. External lustre glassy, 3 to 4; internal, 1 to 2. Transparency from 2 to 3; sometimes 1. Hardness from 7 to 10. Sp. gr. 3.023 to 3.45. Colour leek or dark green.

This stone is often the matrix of iron, copper, and tin ores.

SPECIES 5. Lamellar actinolite.

90 Lamellar actinolite. This stone resembles hornblende. It is amorphous. Texture foliated. Lustre various in different places. Transparency 0, or scarce 1. Sp. gr. 2.916. Colour dark yellowish or greenish grey.

SPECIES 6. Glassy actinolite.

91 Glassy actinolite. This stone is found amorphous, composed of fibres adhering longitudinally, or in slender four or six sided prisms. Texture fibrous. Fragments long splintery, so sharp that they can scarcely be handled without injury. External lustre glassy or silky, 3 to 4; internal 0. Transparency 2. Exceedingly brittle. Sp. gr. 2.95 to 3.493. Colour leek green; sometimes verging towards greenish or silver white; sometimes stained with yellowish or brownish red. According to Bergman it is composed of

72.0	silica,
12.7	carbonat of magnesia,
6.0	carbonat of lime,
7.0	oxyd of iron,
2.0	alumina.
99.7 *	

* Opusc. iv. 171

GENUS XXI. SL.

SPECIES 1. Shistose hornstone †.

G. XXI. SL. Shistose hornstone. The structure of this stone is slaty. Lustre from 0 to 1. Commonly opaque. Hardness 9 to 10. Sp. gr. from 2.596 to 2.641. Colour dark bluish or blackish grey. Infusible *per se*.

† Kirwan, i. 305.

Variety 1. Siliceous shistus.

Commonly intersected by reddish veins of iron stone. Fracture splintery. Lustre 0. Transparency from 0 to 1.

Variety 2. Basanite or Lydian stone.

Commonly intersected by veins of quartz. Fracture even; sometimes inclining to conchoidal. Lustre scarce 1. Hardness 10. Sp. gr. 2.596. Powder black. Colour greyish black.

This, or a stone similar to it, was used by the ancients as a touchstone. They drew the metal to be examined along the stone, and judged of its purity by the

(K) *Kirw. Min.* I. 165. Is this the *tremolite* of Werner? It certainly is not the *tremolite* of the French mineralogists.

(L) Hence the name *pyroxen* given it by Hauy; from πυρ *fire*, and ξενος, *a stranger*. It means, as he himself explains it, a *stranger in the regions of fire*. By this he means to indicate, that pyroxen, though present in lava, is not a volcanic production.

(M) In this and the following species we have followed Mr Kirwan's new arrangement exactly, without even venturing to give the synonimes of other authors. The descriptions which have been given are so many and incomplete, and the minerals themselves are still so imperfectly known, and have got so many names, that no part of mineralogy is in a state of greater confusion.

Earths and Stones.

the colour of the metallic ſtreak. On this account they called it [illegible], *the trier*. They called it alſo *Lydian ſtone*, becauſe, as Theophraſtus informs us, it was found moſt abundantly in the river Tmolus in Lydia†. A ſpecimen of the firſt variety, analyſed by Wiegleb, contained

75.0	ſilica,
10.0	lime,
4.6	magneſia,
3.5	iron,
5.2	carbon.
98.3	

† Hill's Theophraſtus, [illegible] p. 192.

This ſpecies is rather a mechanical mixture than a chemical combination.

93 G. XXII. Zs. Zircon.

Genus XXII. Zs.

Species 1. Zircon*.

Jargon—Hyacinth.

* Kirwan, i. 257. and 333.

This ſtone is brought from Ceylon, and found alſo in France, Spain, and other parts of Europe. It is commonly cryſtallized. The primitive form of its cryſtals is an octahedron§, compoſed of two four-ſided pyramids applied baſe to baſe, whoſe ſides are iſoſceles triangles (N). The inclination of the ſides of the ſame pyramid to each other is 124° 12′; the inclination of the ſides of one pyramid to thoſe of another 82° 50′. The ſolid angle at the apex is 73° 44′†. The varieties of the cryſtalline forms of zircon amount to ſeven. In ſome caſes there is a four ſided priſm interpoſed between the pyramids of the primitive form; ſometimes all the angles of this priſm are wanting, and two ſmall triangular faces in place of each; ſometimes the cryſtals are dodecahedrons, compoſed of a flat four-ſided priſm with hexagonal faces, terminated by four-ſided ſummits with rhomboidal faces‖; ſometimes the edges of this priſm, ſometimes the edges where the priſm and ſummit join, and ſometimes both together, are wanting, and we find ſmall faces in their place. For an accurate deſcription and figure of theſe varieties, we refer to *Mr Hauy*‡.

§ Fig. 25.

† Hauy. Jour. de Min. N° xxvi. 91.

‖ Fig. 26.

‡ Ibid.

The texture of the zircon is foliated. Internal luſtre 3. Tranſparency from 4 to 2. Cauſes a very great double refraction. Hardneſs from 10 to 16. Sp. gr. from 4.2 to 4.165†. Colour commonly reddiſh or yellowiſh; ſometimes it is limpid.

† Ibid.

Before the blow pipe it loſes its colour, but not its tranſparency. With borax it melts into a tranſparent glaſs. Infuſible with fixed alkali and microcoſmic ſalt.

1. The variety formerly called *hyacinth* is of a yellowiſh red colour, mixed with brown. Its ſurface is ſmooth. Its luſtre 3. Its tranſparency 3 to 4.

2. The variety formerly called *jargon of Ceylon*, is either grey, greeniſh, yellowiſh brown, reddiſh brown, or violet. It has little external luſtre. Is ſometimes nearly opaque.

The firſt variety, according to the analyſis of Vauquelin, is compoſed of

64.5	zirconia,
32.0	ſilica,
2.0	oxyd of iron.
98.5†	

† Ibid. p. 106.

Saline Stones.

A ſpecimen analyſed by Klaproth contained

70.0	zirconia,
25.0	ſilica,
0.5	oxyd of iron.
95.5‡	

‡ Beiträge, i. 231.

The ſecond variety, according to Klaproth, who diſcovered the component parts of both theſe ſtones, contains

68.0	zirconia,
31.5	ſilica,
0.5	nickel and iron.
100.0§	

§ Ibid. i. 219.

Order II. SALINE STONES.

Under this order we comprehend all the minerals which conſiſt of an earthy baſis combined with an acid. They naturally divide themſelves into five genera. We ſhall deſcribe them in the following order. 94 Genera.

I. Calcareous salts.
- Carbonat of lime,
- Sulphat of lime,
- Phoſphat of lime,
- Fluat of lime,
- Borat of lime.

II. Barytic salts.
- Carbonat of barytes,
- Sulphat of barytes.

III. Strontitic salts.
- Carbonat of ſtrontites,
- Sulphat of ſtrontites.

IV. Magnesian salts.
- Sulphat of magneſia.

V. Aluminous salts.
- Alum.

Genus I. Calcareous salts. 95 G. I. Calcareous ſalts.

This genus comprehends all the combinations of lime and acids which form a part of the mineral kingdom.

Species 1. Carbonat of lime. 96 Carbonat of lime.

No other mineral can be compared with carbonat of lime in the abundance with which it is ſcattered over the earth. Many mountains conſiſt of it entirely, and hardly a country is to be found on the face of the globe, where, under the names of limeſtone, chalk, marble, ſpar, it does not conſtitute a greater or ſmaller part of the mineral riches.

It is often amorphous, often ſtalactitical, and often cryſtallized. The primitive form of its cryſtals is a parallelopiped, whoſe ſides are rhombs, with angles of 77° 30′ and 102° 30′‡. Its integrant molecules have the ſame form. The varieties of its cryſtals amount to more than 40; for a deſcription and figure of which we refer to *Romé de Liſle** and *Hauy* (O).

‡ Fig. 28.

* Cryſtal. i. 497.

When cryſtallized, its texture is foliated; when amorphous, its ſtructure is ſometimes foliated, ſometimes ſtriated, ſometimes granular, and ſometimes earthy. Its luſtre

(N) Let ABC (fig. 27.) be one of the ſides. Draw the perpendicular BD; then AB = 5, BD = 4, AD = 3.

(O) *Eſſai d'une Theorie*, &c. p. 75.—*Jour. de Phyſ.* 1793, Auguſt, p. 114.—*Jour. d'Hiſt. Nat.* 1792, February, p. 148.—*Ann. de Chim.* XVII. 249. &c.—*Jour de Min.* N° XXVIII. 304.

Earths and Stones. lustre varies from 0 to 3. Transparency from 0 to 4. It causes double refraction; and it is the only mineral which causes double refraction through two parallel faces of the crystal. Hardness from 3 to 9. Sp. gr. from 2.315 to 2.78. Colour, when pure, white. Effervesces violently with muriatic acid, and dissolves completely, or leaves but a small residuum. The solution is colourless.

This species occurs in a great variety of forms; and therefore has been subdivided into numerous varieties. All these may be conveniently arranged under two general divisions.

I. Soft carbonat of lime.

Variety 1. Agaric mineral.

Mountain milk, or *mountain meal* of the Germans.

This variety is found in the clefts of rocks, or the bottom of lakes. It is nearly in the state of powder; of a white colour, sometimes with a shade of yellow; and so light, that it almost floats on water.

Variety 2. Chalk.

The colour of chalk is white, sometimes with a shade of yellow. Lustre 0. Opaque. Hardness 3 to 4. Sp. gr. from 2.315 to 2.657. Texture earthy. Adheres slightly to the tongue. Feels dry. Stains the fingers, and marks. Falls to powder in water. It generally contains about $\frac{2}{100}$ of alumina, and $\frac{2}{100}$ of water; the rest is carbonat of lime.

Variety 3. Arenaceous limestone.

Colour yellowish white. Lustre 1. Transparency 1. So brittle, that small pieces crumble to powder between the fingers. Sp. gr. 2.742. Phosphoresces in the dark when scraped with a knife, but not when heated. It consists almost entirely of pure carbonat of lime.

Variety 4. Testaceous tufa.

The colour of this variety is yellowish or greyish white. It is exceedingly porous and brittle; and is either composed of broken shells, or resembles mortar containing shells; or it consists of fistulous concretions variously ramified, and resembling moss.

II. Indurated carbonat of lime.

Variety 1. Compact limestone.

The texture of this variety is compact. It has little lustre; and is most commonly opaque. Hardness 5 to 8. Sp. gr. 1.3864 to 2.72. Colour grey, with various shades of other colours. It most commonly contains about $\frac{1}{12}$th of alumina, oxyd of iron, &c.; the rest is carbonat of lime. This variety is usually burnt as lime.

Variety 2. Granularly foliated limestone.

Structure sometimes slaty. Texture foliated and granular. Lustre 2 to 1. Transparency 2 to 1. Hardness 7 to 8. Sp. gr. 2.71 to 2.8376. Colour white, of various shades from other colours.

Variety 3. Sparry limestone.

Structure sparry. Texture foliated. Fragments rhomboidal. Lustre 2 to 3. Transparency from 2 to 4; sometimes 1. Hardness 5 to 6. Sp. gr. from 2.693 to 2.718. Colour white: often with various shades of other colours. To this variety belong all the crystals of carbonat of lime.

Variety 4. Striated limestone.

Texture striated or fibrous. Lustre 1 to 0. Transparency 2 to 1. Hardness 5 to 7. Sp. gr. commonly from 2.6 to 2.77. Colours various.

Variety 5. Swine stone.

Saline Stones. Texture often earthy. Fracture often splintery. Lustre 1 to 0. Transparency 0 to 1. Hardness 6 to 7. Sp. gr. 2.701 to 2.7121. Colour dark grey, of various shades. When scraped or pounded, it emits an urinous or garlic smell.

Variety 6. Oviform.

This variety consists of a number of small round bodies, closely compacted together. Lustre 0. Transparency 0 or 1. Hardness 6 to 7.

SPECIES 2. Sulphat of lime. 97 Sulphat of lime.

Gypsum—Selenite.

This mineral is found abundantly in Germany, France, England, Italy, &c.

It is found sometimes in amorphous masses, sometimes in powder, and sometimes crystallized. The primitive form of its crystals, according to Romé de Lisle, is a decahedron ‡, which may be conceived as two four-sided pyramids, applied base to base, and which, instead of terminating in pointed summits, are truncated near their bases; so that the sides of the pyramids are trapeziums, and they terminate each in a rhomb. These rhombs are the largest faces of the crystal. The angles of the rhombs are 52° and 158°. The inclination of two opposite faces of one pyramid to the two similar faces of the other pyramid is 145°, that of the other faces 110° *. Sometimes some of the faces are elongated: sometimes it crystallizes in six-sided prisms, terminated by three or four sided summits, or by an indeterminate number of curvilinear faces. For a description and figure of these varieties, we refer to *Romé de Lisle* †.

‡ Fig. 29.

* *Crystal.* 144.

† *Ibid.*

The texture of sulphat of lime is most commonly foliated. Lustre from 0 to 4. Transparency from 0 to 4. It causes double refraction. Its hardness does not exceed 4. Its sp. gr. from 1.872 to 2.311. Colour commonly white or grey.

Before the blow-pipe, it melts into a white enamel, provided the blue flame be made to play upon the edges of its laminæ. When the flame is directed against its faces, the mineral falls into powder †.

† *Le Lievre, Jour de Min*, N° xxviii. 315.

It does not effervesce with muriatic acid, except it be impure; and it does not dissolve in it.

The following varieties of this mineral are deserving of attention.

Variety 1. Broad foliated sulphat.

Texture broad foliated. Lustre glassy, from 4 to 2. Transparency from 4 to 3. Hardness 4. Sp. gr. 2.311. Colour grey, often with a shade of yellow.

Variety 2. Grano-foliated sulphat.

Texture foliated, and at the same time granular; so that it easily crumbles into powder. Lustre 2 to 3. Transparency 2 to 3. Hardness 4 to 3. Sp.gr. from 2.274 to 2.310. Feels soft. Colour white or grey, often with a tinge of yellow, blue, or green; sometimes flesh red, brown, or olive green.

Variety 3. Fibrous sulphat.

Texture fibrous. Fragments long splintery. Lustre 2 to 3. Transparency 2 to 1; sometimes 3. Hardness 4. Brittle. Sp. gr. 2.300. Colour white, often with a shade of grey, yellow, or red; sometimes flesh red, and sometimes honey yellow; sometimes several of these colours meet in stripes.

Variety 4. Compact sulphat.

Texture compact. Lustre 1 or 0. Transparency 2 to

1,

1, sometimes – Hardness 4. Sp. gr. from 1.872 to 2.288. Feels dry, but not harsh. Colour white, with a shade of grey, yellow, blue, or green: sometimes yellow; sometimes red; sometimes spotted, striped, or veined.

Variety 5. Farinaceous sulphat.

Of the consistence of meal. Lustre 0. Opaque. Scarcely sinks in water. Is not gritty between the teeth. Feels dry and meagre. Colour white. When heated below redness, it becomes of a dazzling white.

95 Phosphat of lime.

SPECIES 3. Phosphat of lime.

Apatite – *Phosphorite* – *Chrysolite*—of the French.

This substance is found in Spain, where it forms whole mountains, and in different parts of Germany. It is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals is a regular six-sided prism ‡. Its integrant molecule is a regular triangular prism, whose height is to a side of its base as 1 to $\sqrt{2}$ §. Sometimes the edges of the primitive hexagonal prism are wanting, and small faces in their place; sometimes there are small faces instead of the edges which terminate the prism; sometimes these two varieties are united; sometimes the terminating edges and the angles of the prism are replaced by small faces †; and sometimes the prism is terminated by four-sided pyramids *.

‡ Fig. 30.

§ *Hauy, Jour. de Min* N° xxviii p. 310.

† Fig. 31

* *Hauy, ibid.*

Its texture is foliated. Its fracture uneven, tending to conchoidal. External lustre from 2 to 3, internal 3 to 2. Transparency from 4 to 2. Causes single refraction. Hardness 6 to 7. Brittle. Sp. gr. from 2.8249 to 3.218. Colour commonly green or grey; sometimes brown, red, blue, and even purple.

It is infusible by the blow-pipe. When its powder is thrown upon burning coals, it emits a yellowish green phosphorescent light. It is soluble in muriatic acid without effervescence or decomposition, and the solution often becomes gelatinous.

99 Fluat of lime.

SPECIES 4. Fluat of lime.

Fluor.

This mineral is found abundantly in different countries, particularly in Derbyshire. It is both amorphous and crystallized.

The primitive form of its crystals is the regular octohedron; that of its integrant molecules the regular tetrahedron *. The varieties of its crystals hitherto observed amount to 7. These are the primitive octohedron; the cube; the rhomboidal dodecahedron; the cubo octohedron †, which has both the faces of the cube and of the octohedron; the octohedron wanting the edges; the cube wanting the edges, and either one face ‡, or two faces in place of each. For a description and figure of these we refer to *Mr Hauy* †.

* *Hauy, ibid* p. 325.

† Fig. 32.

‡ Fig. 33.

† *Ibid.*

The texture of fluat of lime is foliated. Lustre from 2 to 3, sometimes 0. Transparency from 2 to 4, sometimes 1. Causes single refraction. Hardness 8. Very brittle. Sp gr. from 3.0943 to 3.1911. Colours numerous, red, violet, green, red yellow, blackish purple. Its powder thrown upon hot coals emits a bluish or greenish light. Two pieces of it rubbed in the dark phosphoresce. It decrepitates when heated. Before the blow-pipe it melts into a transparent glass ‡.

‡ *Ibid.*

It admits of a polish, and is often formed into vases and other ornaments.

100 Borat of lime.

SPECIES 5. Borat of lime.

Boracite

This mineral has been found at Kalkberg near Luneburg, seated in a bed of sulphat of lime. It is crystallized. The primitive form of its crystals is the cube §. In general, all the edges and angles of the cube are truncated; sometimes, however, only the alternate angles are truncated *. The size of the crystals does not exceed half an inch.

§ *Hauy, Jour. de Min.* N° xxv i p. 325

* *Hauy* and *Westrum.*

The texture of this mineral is compact. Its fracture is flat conchoidal. External lustre 3; internal, greasy, 2. Transparency from 2 to 3. Hardness 9 to 10. Sp. gr. 2.566. Colour greyish white, sometimes passing into greenish white or purplish.

When heated it becomes electric; and the angles of the cube are alternately positive and negative †.

† *Hauy, ibid.* and *Ann. de Chim.* ix. 59.

Before the blow-pipe it froths, emits a greenish light, and is converted into a yellowish enamel, garnished with small points, which, if the heat be continued, dart out in sparks ‖.

‖ *Le Lievre, Jour. de Min. ibid.*

According to Westrum, who discovered its component parts, it contains

68	boracic acid,
13.5	magnesia,
11	lime,
1	alumina,
2	silica,
1	iron.
96 §	

§ *Ann. de Chim.* ii. 116.

SPECIES 6. Nitrat of lime.

101 Nitrat of lime.

Found abundantly mixed with native nitre. For a description see the article CHEMISTRY in this *Supplement*, n° 672.

102 Genus II. Barytic salts.

GENUS II. BARYTIC SALTS.

This genus comprehends the combinations of barytes with acids.

103 Carbonat of barytes.

SPECIES 1. Carbonat of barytes.

Witherite.

This mineral was discovered by Dr Withering; hence Werner has given it the name of *witherite*. It is found both amorphous and crystallized. The crystals are octohedrons or dodecahedrons, consisting of four or six sided pyramids applied base to base; sometimes the six-sided pyramids are separated by a prism; sometimes several of these prisms are joined together in the form of a star.

Its texture is fibrous. Its fracture conchoidal. Its fragments long splintery. Lustre 2. Transparency 2 to 3. Hardness 5 to 6. Brittle. Sp. gr. 4.3 to 4.338. Colour greenish white. When heated it becomes opaque. Its powder phosphoresces when thrown on burning coals *.

* *Hauy.*

It is soluble with effervescence in muriatic acid. The solution is colourless.

According to Pelletier it contains

62	barytes,
22	carbonic acid,
16	water.
100 †	

† *Jour. de Min.* N° xxi. p 46.

104 Sulphat of barytes.

SPECIES 2. Sulphat of barytes.

Borosélenite.

This mineral is found abundantly in many countries, particularly in Britain. It is sometimes in powder, often in amorphous masses, and often crystallized. The primitive form of its crystals is a rectangular prism, whose

Earths and Stones.

whose bases are rhombs, with angles of 101° 30' and 78° 30' ‡. The varieties of its crystals are very numerous. For a description and figure of them we refer to *Rom de Lisle* || and *Hauy* *. The most common varieties are the octohedron with cuneiform summits, the six or four sided prism, the hexangular table with bevelled edges. Sometimes these crystals are needle form.

Its texture is commonly foliated. Lustre from 0 to 2. Transparency from 2 to 0; in some cases 3 or 4. Hardness from 5 to 6. Sp. gr. from 4.4 to 4.44. Colour commonly white, with a shade of yellow, red, blue, or brown.

‡ *Hauy, Ess. d'une Theorie*, &c. p. 119.

|| *Crystal.* i. 588.

* *Ibid.* and *Ann de Chim* xii. 3.

When heated it decrepitates. It is fusible *per se* by the blue flame of the blow-pipe, and is converted into sulphuret of barytes. Soluble in no acid except the sulphuric; and precipitated from it by water.

Variety 1. Foliated sulphat.

Lustre 3 to 3. Transparency from 4 to 2, sometimes 1. Colours white, reddish, bluish, yellowish, blackish, greenish. Mr Werner subdivides this variety into three, according to the nature of the texture. These three subdivisions are *granularly foliated*, *straight foliated*, *curve foliated*.

Variety 2. Fibrous sulphat.

Texture fibrous; fibres converging to a common centre. Lustre silky or waxy, 2. Transparency 2 to 1. Hardness 5. Colours yellowish, bluish, reddish.

Variety 3. Compact sulphat.

Texture compact, Lustre 0 to 1. Transparency 1 to 0. Feels meagre. Almost constantly impure. Colours light yellow, red, or blue.

Variety 4. Earthy sulphat.

In the form of coarse dusty particles, slightly cohering. Colour reddish or yellowish white.

105 G. III. Strontitic Salts.

GENUS III. STRONTITIC SALTS.

This genus comprehends all the combinations of strontites and acids which form a part of the mineral kingdom.

106 Carbonat of strontites.

SPECIES 1. Carbonat of strontites.

This mineral was first discovered in the lead mine of Strontion in Argyleshire; and since that time it is said to have been discovered, though not in great abundance, in other countries. It is found amorphous, and also crystallized in needles, which, according to Hauy, are regular six sided prisms.

Its texture is fibrous; the fibres converge. Fracture uneven. Lustre 2. Transparency 2. Hardness 5. Sp. gr. from 3.4 to 3.66. Colour light green. Does not decrepitate when heated. Before the blow pipe becomes opaque and white, but does not melt. With borax it effervesces, and melts into a transparent colourless glass. Effervesces with muriatic acid, and is totally dissolved. The solution tinges flame purple.

107 Sulphat of strontites.

SPECIES 2. Sulphat of strontites.

Celestine.

This mineral has been found in Pennsylvania, in Germany, in France, in Sicily, and Britain. It was first discovered near Bristol by Mr Clayfield. There it is found in such abundance, that it has been employed in mending the roads.

It occurs both amorphous and crystallized. The crystals are most commonly bevelled tables, sometimes rhomboidal cubes. Its texture is foliated. More or less transparent. Hardness 5. Sp. gr. from 3.51 to 3.96. Colour most commonly a fine sky blue; sometimes reddish; sometimes white, or nearly colourless *.

Aggregates.

* *Cl. of M. Nicholson's Jour.* iii. 56.

Klaproth found a specimen of this mineral from Pennsylvania composed of

58 strontites,
42 sulphuric acid.

100 †

† *Beiträge*, ii. 97.

According to the analysis of Mr Clayfield, the sulphat of strontites found near Bristol is composed of

58.25 strontites,
41.75 sulphuric acid of 2.24, and a little iron ‡.

100.00

‡ *Ibid. Nicholson's Journal.*

According to the analysis of Vauquelin, the sulphat of strontites found at Bouvron in France, which was contaminated with .1 of carbonat of lime, is composed of

54 strontites,
45 sulphuric acid.

99 §

§ *Jour. de Min.* N° xxxvii. 6.

108 G. IV. Magnesian Salts.

GENUS IV. MAGNESIAN SALTS.

This genus comprehends the combinations of magnesia and acids which occur in the mineral kingdom. Only two species have hitherto been found; namely,

109 Sulphat of magnesia.

SPECIES 1. Sulphat of magnesia.

It is found in Spain, Bohemia, Britain, &c.; and enters into the composition of many mineral waters. For a description of it, we refer to CHEMISTRY, n° 633. in this *Suppl.*

110 Nitrat of magnesia.

SPECIES 2. Nitrat of magnesia.

Found sometimes associated with nitre. For a description see CHEMISTRY, n° 674.

111 G. V. Aluminous salts.

GENUS V. ALUMINOUS SALTS.

This genus comprehends those combinations of alumina and acids which occur in the mineral kingdom.

112 Alum.

SPECIES 1. Alum.

This salt is found in crystals, in soft masses, in flakes, and invisibly mixed with the soil. For a description, we refer to CHEMISTRY, n° 636.

ORDER III. AGGREGATES.

THIS order comprehends all mechanical mixtures of earths and stones found in the mineral kingdom. These are exceedingly numerous: the mountains and hills, the mould on which vegetables grow, and indeed the greater part of the globe, may be considered as composed of them. A complete description of aggregates belongs rather to geology than mineralogy. It would be improper, therefore, to treat of them fully here. But they cannot be altogether omitted; because aggregates are the first substances which present themselves to the view of the practical mineralogist, and because, without being acquainted with the names and component parts of many of them, the most valuable mineralogical works could not be understood.

113 Divisions of aggregates.

Aggregates may be comprehended under four divisions: 1. Mixtures of earths; 2. Amorphous fragments of stones agglutinated together; 3. Crystallized stones, either agglutinated together or with amorphous stones; 4. Aggregates formed by fire. It will be exceedingly convenient

Earth and Stones. convenient to treat each of these separately. We shall therefore divide this order into four sections.

Sect. I. *Aggregates of Earths.*

The most common earthy aggregates may be comprehended under the following genera:

1. Clay,
2. Colorific earths,
3. Marl,
4. Mould.

114 Clay.

Genus I. Clay.

Clay is a mixture of alumina and silica in various proportions. The alumina is in a state of an impalpable powder; but the silica is almost always in small stones, large enough to be distinguished by the eye. Clay, therefore, exhibits the character of alumina, and not of silica, even when this last ingredient predominates. The particles of silica are already combined with each other; and they have so strong an affinity for each other, that few bodies can separate them; whereas the alumina, not being combined, readily displays the characters which distinguish it from other bodies. Besides alumina and silica, clay often contains carbonat of lime, of magnesia, barytes, oxyd of iron, &c. And as clay is merely a mechanical mixture, the proportion of its ingredients is exceedingly various.

Clay has been divided into the following species:

115 Porcelain clay.

Species 1. Porcelain clay.

Its texture is earthy. Its lustre 0. Opaque. Hardness 4. Sp. gr. from 2.23 to 2.4. Colour white, sometimes with a shade of yellow or red. Adheres slightly to the tongue. Feels soft. Falls to powder in water.

A specimen, analysed by Hassenfratz, contained

62 silica,
19 alumina,
12 magnesia,
7 sulphat of barytes.

———

100 *

A specimen, analysed by Mr Wedgewood, contained

60 alumina,
20 silica,
12 air of water.

———

92

116 Common clay.

Species 2. Common clay.

Its texture is earthy. Lustre 0. Opaque. Hardness 3 to 6. Sp. gr. 1.8 to 2.68. Adheres slightly to the tongue. Often feels greasy. Falls to powder in water. Colour, when pure, white; often tinged blue or yellow.

Variety 1. Potter's clay.

Hardness 3 to 4. Sp. gr. 1.8 to 2. Stains the fingers slightly. Acquires some polish by friction. Colour white; often with a tinge of yellow or blue; sometimes brownish, greenish, reddish. Totally diffusible in water; and, when duly moistened, very ductile.

Variety 2. Indurated clay.

Hardness 5 to 6. Does not diffuse itself in water, but falls to powder. Discovers but little ductility. Colours grey, yellowish, bluish, greenish, reddish, brownish.

* *Ann. de Chim.* xiv. 144.

Variety 3. Shistose clay.

Structure slaty. Sp. gr. from 2.6 to 2.68. Feels smooth. Streak white or grey. Colour commonly bluish, or yellowish grey; sometimes blackish, reddish, greenish. Found in strata, usually in coal mines.

This variety is sometimes impregnated with bitumen. It is then called bituminous *shale*.

Species 3. Lithomarga. 117 Lithomarga.

Texture earthy. Fracture conchoidal. Lustre from 0 to 2. Opaque. Hardness 3 to 7. Sp. gr. when pretty hard, 2.815. Surface smooth, and feels soapy. Adheres strongly to the tongue. Falls to pieces, and then to powder, in water; but does not diffuse itself through that liquid. Fusible *per se* into a frothy mass.

Variety 1. Friable lithomarga.

Formed of scaly particles slightly cohering. Lustre 1 to 0. Hardness 3 to 4. Exceedingly light. Feels very smooth, and assumes a polish from the nail. Colour white; sometimes tinged yellow or red.

Variety 2. Indurated lithomarga.

Hardness 4 to 7. The softer sorts adhere very strongly to the tongue when newly broken; the harder very moderately. Colours grey, yellow, red, brown, blue.

A specimen of lithomarga from Osmund, analysed by Bergman, contained

60.0 silica,
11.0 alumina,
5.7 carbonat of lime,
4.7 oxyd of iron,
0.5 carbonat of magnesia,
18.0 water and air.

———

99.9 †

† *Opusc.* iv.

Species 4. Bole. 118 Bole.

Texture earthy. Fracture conchoidal. Lustre 0. Transparency scarce 1. Hardness 4. Sp. gr. from 1.4 to 2. Acquires a polish by friction. Scarcely adheres to the tongue. Feels greasy. Colour yellow or brown; sometimes red; sometimes spotted.

The lemnian earth which belongs to this species, according to the analysis of Bergman, contains

47.0 silica,
19.0 alumina,
6.0 carbonat of magnesia,
5.4 carbonat of lime,
5.4 oxyd of iron,
17.0 water and air.

———

99.8 ‡

‡ *Ibid*, p. 157.

Species 5. Fullers earth. 119 Fullers earth.

Texture earthy. Structure sometimes slaty. Fracture imperfectly conchoidal. Lustre 0. Opaque. Hardness 4. Receives a polish from friction. Does not adhere to the tongue. Feels greasy. Colour usually light green.

A specimen from Hampshire, analysed by Bergman, contained

51.8 silica,
25.0 alumina,
3.3 carbonat of lime,
3.7 oxyd of iron,
0.7 carbonat of magnesia,
15.5 moisture.

———

100.0 §

§ *Ibid*, 159.

This

Earths and Stones.

This earth is used by fullers to take the grease out of their cloth before they apply soap. It is essential to fullers earth that the particles of silica be very fine, otherwise they would cut the cloth. Any clay, possessed of this last property, may be considered as *fullers earth*; for it is the alumina alone which acts upon the cloth, on account of its strong affinity for greasy substances.

120 G. II. Colorific earths.

GENUS II. COLORIFIC EARTHS.

The minerals belonging to this genus consist of clay, mixed with so large a quantity of some colouring ingredient as to render them useful as paints. The colouring matter is commonly oxyd of iron, and sometimes charcoal.

121 Red chalk.

SPECIES 1. Red chalk.

Reddle.

Texture earthy. Fracture conchoidal. Lustre 0. Opaque. Hardness 4. Sp. gr. inconsiderable. Colour dark red.

Feels rough. Stains the fingers. Adheres to the tongue. Falls to powder in water. Does not become ductile. When heated it becomes black, and at 159° Wedgewood melts into a greenish yellow frothy enamel.

Composed of clay and oxyd of iron.

122 Yellow chalk.

SPECIES 2. Yellow chalk.

Texture earthy. Fracture conchoidal. Hardness 3. Sp. gr inconsiderable. Colour ochre yellow.

Feels smooth or greasy. Stains the fingers. Adheres to the tongue. Falls to pieces in water. When heated becomes red; and at 156° Wedgewood melts into a brown porous porcelain.

According to Sage, it contains

50 alumina,
40 oxyd of iron,
10 water, with some sulphuric acid.

100 *

* Mem. Par. 1779, 313.

123 Black chalk.

SPECIES 3. Black chalk.

Structure slaty. Texture earthy. Fragments splintery. Lustre 0. Opaque. Hardness 5. Sp. gr. 2.144 to 2.277. Colour black. Streak black.

Feels smooth. Adheres slightly to the tongue. Does not moulder in water. When heated to redness it becomes reddish grey.

According to Wiegleb, it is composed of

64.50 silica,
11.25 alumina,
11.00 charcoal,
2.75 oxyd of iron,
7.50 water.

97.00 †

† Ann. de Chim. xxx. 13.

124 Green earth.

SPECIES 4. Green earth.

Texture earthy. Lustre 0. Opaque. Hardness 6 to 7. Sp gr. 2.637. Colour green.

Commonly feels smooth. Does not stain the fingers. Often falls to powder in water. When heated it becomes reddish brown; and at 147° Wedgewood melts into a black compact glass.

Composed of clay, oxyds of iron and nickel.

125 G. III. Marl.

GENUS III. MARL.

A mixture of carbonat of lime and clay, in which the carbonat considerably exceeds the other ingredient, is called *marl*. Aggregates.

Its texture is earthy. Lustre 0. Opaque. Hardness from 4 to 8; sometimes in powder. Sp. gr. from 1.6 to 2.877. Colour usually grey, often tinged with other colours. Effervesces with acids.

Some marls crumble into powder when exposed to the air; others retain their hardness for many years.

Marls may be divided into two species: 1. Those which contain more silica than alumina; 2. Those which contain more alumina than silica. Mr Kirwan has called the first of these *siliceous*, the second *argillaceous*, marls. Attention should be paid to this distinction when marls are used as a manure.

GENUS IV. MOULD. 126 G. IV. Mould.

By *mould* is meant the soil on which vegetables grow.

It contains the following ingredients: silica, alumina, lime, magnesia (sometimes), iron, carbon derived from decayed vegetable and animal substances, carbonic acid, and water. And the good or bad qualities of *soils* depends upon a proper mixture of these ingredients. The silica is seldom in the state of an impalpable powder, but in grains of a greater or smaller size: Its chief use seems to be to keep the soil open and pervious to moisture. If we pass over the carbon, the iron, and the carbonic acid, the goodness of a soil depends upon its being able to retain the quantity of moisture which is proper for the nourishment of vegetables, and no more. Now the retentive power of a soil increases with the proportion of its alumina, lime, or magnesia, and diminishes as the proportion of its silica increases. Hence it follows, that in a dry country, a fertile soil should contain less silica, and more of the other earths, than in a wet country.

Giobert found a fertile soil near Turin, where it rains annually 30 inches, to contain

From 77 to 79 silica,
9 — 14 alumina,
5 — 12 lime.

Near Paris, where it rains about 20 inches annually, Mr Tillet found a fertile soil to contain

Coarse sand 25
Fine sand 21
— 46.0 silica,
16.5 alumina,
37.5 lime.

100.0 ‡

‡ Kirwan on Manures.

The varieties of mould are too numerous to admit an accurate description: we shall content ourselves, therefore, with mentioning the most remarkable.

SPECIES 1. Sand. 127 Sand.

This consists of small grains of siliceous stones not cohering together, nor softened by water. When the grains are of a large size, the soil is called *gravel*.

SPECIES 2. Clay. 128 Clay.

This consists of common clay mixed with decayed vegetable and animal substances.

SPECIES 3. Loam. 129 Loam.

Any soil which does not cohere so strongly as clay, but more strongly than chalk, is called *loam*. There are many varieties of it. The following are the most common.

Earth and Stones.

Variety 1. Clayey loam; called alſo *ſtrong*, *ſtiff*, *cold*, and *heavy*, loam.

It conſiſts of a mixture of clay and coarſe ſand.

Variety 2. Chalky loam.

A mixture of clay, chalk, and coarſe ſand; the chalk predominating.

Variety 3. Sandy loam.

A mixture of the ſame ingredients; the ſand amounting to .8 or .9 of the whole.

130 Till.

SPECIES 4. Till.

Till is a mixture of clay and oxyd of iron. It is of a red colour, very hard and heavy.

SECT. II. *Aggregates of amorphous ſtones.*

THE aggregates which belong to this ſection conſiſt of amorphous fragments of ſtones cemented together. They may be reduced to the following genera:

1. Sandſtone,
2. Puddingſtone,
3. Amygdaloid,
4. Breccia.

131 G. I. Sandſtone.

GENUS I. SANDSTONE.

Small grains of ſand, conſiſting of quartz, flint, hornſtone, ſiliceous ſhiſtus, or felſpar, and ſometimes of mica, cemented together, are denominated ſandſtones. They feel rough and ſandy; and when not very hard, eaſily crumble into ſand. The cement or baſis by which the grains of ſand are united to each other is of four kinds; namely, lime, alumina, ſilica, iron. Sandſtones, therefore, may be divided into four ſpecies.

SPECIES 1. Calcareous ſandſtones.

Calcareous ſandſtones are merely carbonat of lime or marl, with a quantity of ſand interpoſed between its particles. Though the quantity of ſand, in many caſes, far exceeds the lime, calcareous ſandſtones are ſometimes found cryſtallized: and, in ſome caſes, the cryſtals, as might be expected, have ſome of the forms which diſtinguiſh carbonat of lime. Thus the calcareous ſandſtone of Fountainbleau is cryſtallized in rhomboidal tables. It contains, according to the analyſis of Laſſone

62.5 ſiliceous ſand,
37.5 carbonat of lime.
———
100

Calcareous ſandſtones have commonly an earthy texture. Their ſurface is rough. Their hardneſs from 6 to 7. Their ſpecific gravity about 2.5 or 2.6. Their colour grey; ſometimes yellowiſh or brown. They are ſometimes burned for lime.

133 Aluminous.

SPECIES 2. Aluminous ſandſtones.

The baſis of argillaceous ſandſtones is alumina, or rather clay. Their ſtructure is often ſlaty. Their texture is compact, and either fine or coarſe grained, according to the ſize of the ſand of which they are chiefly compoſed. Their hardneſs is from 6 to 8, or even 9. Their colour is uſually grey, yellow, or brown.

They are often formed into mill-ſtones, filtering-ſtones, and coarſe whet ſtones.

134 Siliceous.

SPECIES 3. Siliceous ſandſtones.

Siliceous ſandſtones conſiſt of grains of ſand cemented together by ſilica, or ſome ſubſtance which conſiſts chiefly of ſilica or flint. They are much harder than any of the other ſpecies.

Sometimes ſtones occur, conſiſting of grains of lime cemented together with ſilica. These ſtones are alſo denominated ſiliceous ſandſtones. Aggregates

135 Ferruginous.

SPECIES 4. Ferruginous ſandſtones.

The iron which acts as a cement in ferruginous ſandſtones is not far from a metallic ſtate. When iron is completely oxydated, it loſes the property of acting as a cement. This is the reaſon that ferruginous ſandſtones, when expoſed to the air, almoſt always crumble into powder.

The colour of ferruginous ſandſtones is uſually dark red, yellow, or brown. The grains of ſand which compoſe them are often pretty large. Their hardneſs is commonly inconſiderable.

136 G. II. Pudding ſtone.

GENUS II. PUDDING STONE.

Pebbles of quartz, flint, or other ſimilar ſtones of a round or eliptical form, from the ſize of rape ſeed to that of an egg, cemented together by a ſiliceous cement, often mixed with iron, have been denominated *pudding ſtones*.

Pudding ſtones, of courſe, are not inferior in hardneſs to quartz, flint, chalcedony, &c. of which the pebbles may conſiſt. The colour of the cement is uſually yellow, brown, or red. Its fracture is conchoidal.

The finer ſorts of pudding ſtones are capable of a fine poliſh; the coarſe are uſed for mill-ſtones.

137 G. III. Amygdaloid.

GENUS III. AMYGDALOID.

Rounded or eliptical maſſes of chalcedony, zeolite, limeſtone, lithomarga, ſteatites, green earth, garnets, hornblend, or opal, cemented together by a baſis of indurated clay, trap, mullen, walken or kragg, conſtitute an *amygdaloid*.

Amygdaloids are opaque. They have no luſtre. Their fracture is uneven or conchoidal. Hardneſs 6 to 9. Their colours are as various as the ingredients of which they are compoſed.

138 G. IV. Breccia.

GENUS IV. BRECCIA.

Angular fragments of the ſame *ſpecies* of ſtone agglutinated together, conſtitute a *breccia*. Thus *calcareous* breccia conſiſts of fragments of marble cemented together by means of lime.

SECT. III. *Aggregates of Cryſtals.*

THE minerals belonging to this ſection conſiſt either of cryſtals of different kinds cemented together, or of cryſtals and amorphous ſtones cemented together.

They may be reduced under the following genera.

1. Granite.
2. Sienite.
3. Granatine.
4. Granitell.
5. Granilite.
6. Trap.
7. Porphyry.

139 G. I. Granite.

GENUS I. GRANITE.

An aggregate of felſpath, quartz, and mica, whatever be the ſize or the figure of the ingredients, is denominated *granite*. This aggregate may be divided into two ſpecies, namely, *common* granite, and *ſhiſtoſe* granite or gneiſs.

140 Common.

SPECIES 1. Common granite.

Its ſtructure is always granular. The felſpar is often amor-

Earths and Stones. amorphous, and constitutes most frequently the greatest part of the aggregate.

Common granites differ much in their appearance, according to the size, proportion, colour, and figure of their component parts They are commonly very hard: Their specific gravity varies from 2.5388 to 2.9564.

141 Gneiss. SPECIES 2. Shistose granite or gneiss.

The structure of gneiss is always slaty, and this constitutes its specific character. In gneiss, the proportion of quartz and felspar is nearly equal: the proportion of mica is smallest. It is evidently subject to the same varieties with common granite.

142 G. II. Sienite. GENUS II. Sienite.

Mr Werner has given the name of *sienite* to aggregates composed of felspar, hornblende, and quartz; or of felspar, hornblende, quartz, and mica. These aggregates were formerly confounded with quartz.

Sienite is found both of a granular and slaty structure: it might, therefore, like granite, be divided into two species. In sienite the quartz is commonly in by far the smallest proportion.

143 G. III. Granatine. GENUS III. GRANATINE.

Mr Kirwan has applied the name *granatine* to the following aggregates.

Quartz, Felspar, Shorl.	Quartz, Mica, Garnet.	Quartz, Hornblende, Jade.	Felspar, Mica, Shorl.
Quartz, Felspar, Jade.	Quartz, Shorl, Hornblende,	Quartz, Hornblende, Garnet,	Felspar, Mica, Hornblende.
Quartz, Felspar, Garnet.	Quartz, Shorl, Jade.	Quartz, Jade, Garnet.	Felspar, Quartz, Serpentine.
Quartz, Mica, Shorl.	Quartz, Shorl, Garnet.	Quartz, Hornblende, Hornstone,	Felspar, Quartz, Steatites.
Quartz, Mica, Jade.			

One of these aggregates, namely, *quartz, mica, garnet*, was called by Cronstedt *norka* or *murksten*.

144 G. IV. Granitell. GENUS IV. GRANITELL.

Mr Kirwan gives the name of *granitell* to all aggregates composed of any two of the following ingredients: quartz, felspath, mica, shorl, hornblende, jade, garnet, steatites. The most remarkable of these are:

Quartz, Felspar	Quartz, Hornblende.	Quartz, Steatites.	Felspar, Hornblende.
Quartz, Mica.	Quartz, Jade.	Felspar, Mica.	Felspar, Jade.
Quartz, Shorl.	Quartz, Garnet.	Felspar, Shorl.	Felspar, Garnet.
Mica, Shorl.	Mica, Jade.	Hornblende, Jade.	Jade, Garnet.
Mica, Hornblende.	Mica, Garnet.	Hornblende, Garnet.	Steatites, Shorl.

Some of these aggregates have received particular names. The aggregate of *quartz* and *mica*, when its structure is slaty, is called by Werner *[illegible]* by the Swedes, it is denominated *[illegible]*, whatever be its structure.

The aggregate of hornblende and mica is called *grunstein*, from the dark green colour which it usually has.

145 G. V. Granilite. GENUS V. GRANILITE.

Under the name of *granilite*, Mr Kirwan comprehends all aggregates containing more than three ingredients. Of these the following are the most remarkable.

Quartz, Felspar, Mica, Shorl.	Quartz, Mica, Shorl, Garnet.	Quartz, Sulph. of barytes, Mica, Shorl.
Quartz, Felspar, Mica, Steatites.	Quartz, Felspar, Mica, Garnet	Quartz, Sulph. of barytes, Mica, Hornblende.

146 G. VI. Trap. GENUS VI. TRAP (P).

Under this genus we class not only what has commonly been called *trap*, but also wacken, and taullen, and kragstone of Kirwan.

147 Common. SPECIES 1. Common trap.

This stone is very common in Scotland, and is known by the name of *whinstone*. Whole hills are formed of it; and it occurs very frequently in large rounded detached fragments. Sometimes it assumes the form of immense columns, and is then called *basalt*. The Giant's Causeway in Ireland, the island of Staffa, and the south side of Arthur's Seat in Scotland, are well known instances of this figure

Its texture is earthy or compact. Its fracture uneven. Its lustre commonly 0. Opaque. Hardness 8 to 9. Not brittle. Sp. gr from 2.[illegible] to 3.021 *. Colour black, with a shade of grey, blue, or purple; sometimes blackish or reddish brown: in some cases greenish grey. By exposure to the atmosphere, it often becomes invested with a brownish rind. Before the blow-pipe, it melts *per se* into a more or less black glass.

* Kirwan.

Trap consists of small crystals of hornblende, felspar, olivine, &c. usually set in a ground composed apparently of clay and oxyd of iron. A specimen, in the form of basaltes, from Staffa, analysed by Dr Kennedy of Edinburgh, contained 48 silica,

16 alumina,
16 oxyd of iron,
9 lime,
5 moisture,
4 soda,
1 muriatic acid.

99 †

(P) *Kirw.* I. 231 and 431.—*Faujas de St Fond. Essai sur l'Hyl. Nat des Roch.* [illegible] *Phil. Trans.* passim. See also a very ingenious set of experiments on the fusion of trap, by Sir James Hall in [illegible] V. 43.

Earths and ... A specimen from Salisbury rock, near Edinburgh, contained, according to the analysis of the same gentleman,

46.0	silica,
19.0	alumina,
17.0	oxyd of iron,
8.0	lime,
4.0	moisture,
3.5	soda,
1.0	muriatic acid.
98.5 ‡	

‡ E. Tra. 90. Dr Kennedy conducted these analyses with great ingenuity and judgment; and the discovery in which they terminated, that trap contains soda, is certainly of importance, and may lead to valuable consequences both in a geological and mineralogical view.

148 Wacken. SPECIES 2. Wacken *.

* Kirw. i. 223. This stone often forms considerable parts of hills, and, like trap, is amorphous. Its texture is earthy. Its fracture usually even. Lustre 0. Opaque. Hardness 6 to 9. Sp. gr. from 2.535 to 2.893 †. Colour grey, with a shade of green, black, red, brown. When exposed to the atmosphere, it withers and becomes more grey.

† Kirwan.

It melts into a grey porous slag.

149 Mullen. SPECIES 3. Mullen ‡.

‡ Kirw. i. 225. This stone is also found in considerable masses, and sometimes has a tendency to a columnar form like basalt. Texture earthy. Fracture uneven, and fine splintery. Lustre 0, except from some shining particles of basaltine. Opaque. Hardness from 7 to 9. Sp. gr. from 2.6 to 2.738. Colour ash or bluish grey; sometimes mixed with ochre yellow, in consequence of the decomposition of the stone. At 130° Wedgewood it melts into a black compact glass.

When mullen is exposed to the air, its surface becomes covered with a greyish white rind, sometimes slightly ochry.

150 Kragstone. SPECIES 4. Kragstone *.

* Kirw. i. 226. This stone, which, like the others, forms considerable parts of rocks, was formed into a distinct species by Mr Kirwan. Its texture is earthy. It is exceedingly porous, and the pores are often filled with the crystals of other minerals. Fracture uneven. Lustre 0. Opaque. Hardness 5 to 7. Sp. gr. 2.314. Feels rough and harsh. Colour reddish grey. Streak yellowish grey. At 138° Wedgewood it melts into a reddish brown porcelain mass.

151 G. VII. Porphyry. GENUS VII. PORPHYRY.

Any stone which contains scattered crystals or grains of felspar, visible to the naked eye, is denominated a *porphyry*. Besides felspar, porphyries generally contain small crystals of quartz, hornblende, and mica. These crystals are usually of a different colour from the stone in which they are found, and they are stuck in it as in a cement. It is evident from this definition, that the number of porphyries must be great. Each species receives its name from the stone which forms its basis. To describe them would be unnecessary. We shall only give a catalogue of the principal species.

Aggregates.

1. Hornstone porphyry.
2. Pitchstone porphyry.
3. Hornslate porphyry.
4. Felspar or petunse porphyry.
5. Clay porphyry.
6. Hornblende porphyry.
7. Trap porphyry.
8. Wacken porphyry.
9. Mullen porphyry.
10. Krag porphyry.
11. Argillitic porphyry.
12. Potstone porphyry.
13. Serpentine porphyry.
14. Sandstone porphyry.

The aggregates belonging to this section compose most of the mountains of the globe. In giving an account of them, we have adhered implicitly to the arrangement most generally received by mineralogists. It must be acknowledged, that this arrangement is by no means complete, and that some of the genera are too vague to be of much use. The number of aggregates already discovered is too great for giving to each a particular name. Perhaps it would be better henceforth to adopt the method proposed by Mr Hauy, namely, to constitute the genera from that ingredient which enters most abundantly into the aggregate, and which forms as it were its basis, and to distinguish the species according to the nature and proportion of the other ingredients. According to this plan, the aggregates hitherto discovered have been divided by Hauy into the following genera:

1. Felspathic rock.
2. Quartzous rock.
3. Micaceous rock.
4. Chloritous rock.
5. Serpentine rock.
6. Trappean rock.
7. Hornblendean rock.
8. Petro-siliceous rock.
9. Garnetic rock.
10. Calcareous rock.
11. Argillaceous rock.
12. Corneous rock.

SECT. IV. *Volcanic Aggregates.*

AGGREGATES formed by volcanoes may be reduced to the following genera.

1. Lava.
2. Tufa.
3. Pumice.
4. Ashes.

GENUS I. LAVA. 152 G. I. Lava.

All substances which have issued out of a volcano in a state of fusion are called *lavas*. They have been divided into three species.

SPECIES 1. Vitreous lava. 153 Vitreous.

Found in small pieces.

Texture glossy. Fracture conchoidal. Lustre 3. Transparency from 3 to 1. Hardness 9 to 10. Sp. gr. from 2 to 3. Colour blackish, greenish, or whitish. Commonly somewhat porous.

SPECIES 2. Cellular lava. 154 Cellular.

This species is full of cells. Surface rough and full of cavities. Texture earthy. Lustre 0. Opaque. Hardness 7 to 9. Sp. gr. varies, but does not exceed 2.8. Colour brown or greyish black. Commonly somewhat magnetic.

SPECIES 3. Compact lava. 155 Compact.

This species is the most common of all; it runs into the

the ſecond by inſenſible degrees; and indeed is ſeldom found of any conſiderable ſize without ſome pores. It bears in general a very ſtrong reſemblance to trap.

A ſpecimen of the lava of Catania in Sicily, analyſed by Dr Kennedy, contained

51.0	ſilica,
19.0	alumina,
14.5	oxyd of iron,
9.5	lime,
4.0	ſoda,
1.0	muriatic acid.
99.0 †	

A ſpecimen of the lava of Sta. Venere in Sicily he found to contain

50.75	ſilica,
17.50	alumina,
14.25	oxyd of iron,
10.00	lime,
4.00	ſoda,
1.00	muriatic acid.
97.5 ‡.	

Thus we ſee, that the reſemblance between trap and lava holds not only in their external appearance, but alſo in their component parts.

† Tranſ. Edin. v. 93.

156 G. II. Puzzolana.

Genus II. puzzolana.

Found in ſmall pieces. Surface rough. Texture earthy and porous. Fracture uneven. Luſtre 0. Opaque. Hardneſs 3. Very brittle. Sp. gr. from 2.57 to 2.8. Colour brown or dark grey. Magnetic. Eaſily melts into a black ſlag.

When mixed with lime into a mortar, it poſſeſſes the property of hardening even under water. This property it owes moſt probably, as Mr Kirwan ſuppoſes, to the iron which it contains. The iron decompoſes the water of the mortar, and by this means it becomes too hard to be acted upon by water in a very ſhort time.

157 G. III. Pumice.

Genus III. pumice.

This is a very light ſubſtance ejected from volcanoes. It is porous. Hardneſs 3. Brittle. Sp. gr. below 1. Colour grey or brown.

In ſome varieties the luſtre and tranſparency are 0: in others, the luſtre is glaſſy, 2. Tranſparency from 1 to 2.

158 G. IV. Volcanic aſhes.

Genus IV. volcanic ashes.

Theſe are analogous to the aſhes of common pit coal. Looſe and ſmooth, very light, and fine. Slowly diffuſible in water, and when wet ſomewhat ductile.

Class II. SALTS.

UNDER this claſs we comprehend all the combinations of alkalies with acids which exiſt in the mineral kingdom. As they have been already deſcribed in the article Chemistry, *Suppl.* we ſhall here only give a liſt of their names.

159 Genera.

Genus I. potass.

Sp. 1. Sulphat of potaſs.
2. Nitrat of potaſs.

Genus II. soda.

Sp. 1. Carbonat of ſoda.
2. Sulphat of ſoda.
3. Muriat of ſoda.
4. Borax.

Genus III. ammonia.

Sp. 1. Sulphat of ammonia.
2. Muriat of ammonia.

Class III. COMBUSTIBLES.

160 Genera.

THE combuſtible ſubſtances belonging to the mineral kingdom, excluding the metals, may be comprehended under the following genera.

1. Sulphur.
2. Carbon.
3. Bitumen.
4. Coal.
5. Amber.

Genus I. sulphur.

species 1. Native ſulphur.

This ſubſtance is found abundantly in many parts of the world, eſpecially near volcanoes, as Hecla, Ætna, Veſuvius, the Lipari iſlands, &c. It is either in the ſtate of powder, or maſſive, or cryſtallized. The primitive form of its cryſtals is an octohedron, compoſed of two four-ſided pyramids, joined baſe to baſe †. The ſides of theſe pyramids are ſcalene triangles, and ſo inclined that the plane where the baſes of the pyramids join is a rhomb, whoſe long diagonal is to its ſhort as 5 to 4 *. Sometimes the apices of the pyramids, to uſe the language of De Liſle, are truncated; ſometimes they are ſeparated from each other by a priſm; ſometimes they are truncated near their baſes, and a low four-ſided pyramid riſes from the truncature: this pyramid is alſo ſometimes truncated near its apex ‡. Finally, one of the edges of the pyramids is ſometimes truncated. For figures of theſe varieties, and for the laws of their formation, we refer to *Mr Lefroy* †.

Colour yellow, with a ſhade of green; ſometimes reddiſh (q). Luſtre greaſy, 2. Tranſparency varies from 0 to 4. Cauſes double refraction ‡. Texture compact. Hardneſs 4 to 5. Brittle.—For its other properties, we refer to Chemistry in this *Suppl.*

Sometimes ſulphur is mixed with different proportions of earths. Theſe combinations are hardly ſuſceptible of accurate deſcription.

Sulphur combines alſo with metals. Theſe combinations ſhall be deſcribed in the fourth claſs.

† Fig. 34.

* Romé de Liſle, i. 292. Haüy and Lefroy, Jour. de Min. N° xxix. 337.

‡ Fig.

† Jour. de Min. N° xxix. 337.

‡ Haüy.

161 G. II. Carbon.

Genus II. carbon.

This genus comprehends all minerals compoſed of pure carbon, or of carbon combined with a little earth.

162 Diamond.

species 1. Diamond.

This mineral, which was well known to the ancients,

(q) It then contains arſenic.

[illegible] parts of Asia, particularly in the kingdoms of Golconda and Visapour, it is found also in Brazil.

It is always crystallized; but sometimes so imperfectly, that at the first sight it might pass for amorphous. Its primitive form is a regular octogon; but it more commonly assumes a spheroidal form, and then has nearly 30 curvilinear triangular faces, 6 of which are raised upon each of the faces of the primitive octogon †. Its integrant molecule, according to Hauy, is a regular tetrahedron. — For a more particular account of the crystals of this mineral, we refer the reader to *Mr Romé de Lisle* and *Mr Hauy* †.

Texture foliated. Lustre 4. Transparency from 2 to 4. Causes single refraction. Hardness 20. Sp. gr. 3.5185 to 3.5310 †. Colour various; sometimes limpid, sometimes red, orange, yellow, green, blue, and even blackish.

When rubbed it becomes positively electric, even before it has been cut by the lapidary, which is not the case with any other gem §.

It is composed of pure carbon §.

164 Mineral charcoal.

SPECIES 2. Mineral charcoal.

Kilkenny coal—Wales culm.

This mineral has been found in Hungary, Italy, France, Ireland, and Wales. It occurs in stratified masses, or in lumps nested in clay.

Colour black. Lustre 4, metallic. Opaque. Texture foliated. Hardness 5 to 7. Sp. gr. 1.4 to 1.526. Often stains the fingers. Insoluble in acids. Deflagrates with nitre. Does not burn till wholly ignited, and then consumes slowly without emitting flame or smoke.

It consists almost entirely of *charcoal*, which, as Morveau has proved, is an oxyd of carbon *.

SPECIES 3. Anthracite (R).

Anthracolite.

This substance, as Dolomieu informs us, is found exclusively in the primitive mountains. It is always amorphous. Colour black or brownish black. Lustre 3 to [illegible]. Structure slaty. Fragments rhomboidal. Hardness 6 to 7. Sp. gr. greater than that of coal. Often stains the fingers.

Burns precisely like the last species, and leaves .40 of white ashes. According to Dolomieu, it is composed of [illegible]

64.0 charcoal,
32.5 silica,
3.5 iron,
—
100.0 †

It is probable that the charcoal in the two last substances is in the same state in which it exists in plumbago, combined with oxygen, but not containing so much as charcoal does ‡.

165 G. III. Bitumen.

GENUS III. BITUMEN.

By bitumen we understand, with mineralogists in general, an oil, which is found in different parts of the earth, in various states of consistence. These different states form distinct species; in our arrangement of which we shall be guided by the observations which Mr Hatchett has made in his valuable paper on bituminous substances *.

Combustibles.

SPECIES 1. Naphtha. 167 Naphtha.

This substance is found sometimes on the surface of the water of springs, and sometimes issuing from certain strata. It is found in great abundance in Persia.

It is as fluid and transparent as water. Colour white or yellowish white. Smell strong, but not disagreeable. Sp. gr. when white, .708 * or .729 †; when yellowish, .8475 ‡. Feels greasy. Catches fire on the approach of flame, burns with a white flame, and leaves scarce any residuum.

Insoluble in alcohol. Does not freeze at 0° Fahrenheit. When pure naphtha is exposed to the air, it becomes yellow and then brown; its consistence is increased, and it passes into *petroleum* *.

SPECIES 2. Petroleum. 168 Petroleum.

This substance is also found in Persia, and likewise in many countries in Europe, particularly Italy, France, Switzerland, Germany, Sweden, England, and Scotland.

Not so fluid nor transparent as water. Colour yellow, either pale or with a shade of red or green; reddish brown and reddish black. Smell that of naphtha, but less pleasant. Sp. gr. .8783 *. When burned it yields a soot, and leaves a small quantity of coally residuum.

By exposure to the air it becomes like tar, and is then called *mineral tar* †.

SPECIES 3. Mineral tar. 169 Mineral tar.

This substance is found in many parts of Asia, America, and Europe. It is viscid, and of a black, brownish black, or reddish colour. Smell sometimes strong, but often faint. Sp. gr. 1.1. When burned, emits a disagreeable bituminous smell. By exposure to the air it passes into *mineral pitch* and *maltha* *.

SPECIES 4. Mineral pitch and maltha. 170 Mineral pitch and maltha.

This substance has a strong resemblance to common pitch. When the weather is warm it is soft, and has some tenacity; it is then called *adhesive mineral pitch*: when the weather is cold, it is brittle; its hardness is 5; and its fracture has a glassy lustre. In this state it is called *maltha*. Colour black, dark brown, or reddish. Lustre 2. Opaque. Sp. gr. from 1.45 to 2.07. Does not stain the fingers. On a white hot iron it flames with a strong smell, and leaves a quantity of grey ashes. It is to the presence of the earths which compose these ashes that the great specific gravity of this bitumen is to be ascribed. By farther induration, it passes into *asphalt*.

SPECIES 5. Asphalt. 171 Asphalt.

This substance is found abundantly in many parts of Europe, Asia, and America, especially in the island of Trinidad.

Colour black or brownish black. Lustre greasy 2. Opaque. Fracture conchoidal, of a glassy lustre. Hardness from 7 to 8. Very brittle. Sp. gr. 1.07 to 1.165 *. Feel smooth, but not greasy. Does not stain the fingers. Has little or no smell, unless when rubbed or heated. When heated melts, swells, and inflames; and when pure, burns without leaving any ashes.

SPECIES 6. Elastic bitumen. 172 Elastic bitumen.

Mineral caoutchouc.

This substance was found about the year 1786 in the lead

(R) This name was given by Hauy from [illegible] *coal*.

† Romé de Lisle. ‡ Hauy. § Morveau, Ann. de Chim. xxvi. * Morveau, ibid. ‡ Morveau, ibid. * Nich. Jour. [illegible]

* Muschenbroek. † Bouldoc. ‡ Brisson. * Hatchett. * Brisson. † Hatchett, ibid. * Hatchett, ibid. * Kirwan.

Combus- lead mine of Odin, near Castletown, Derbyshire. It was first mentioned by Mr De Born.

Colour yellowish or reddish brown, sometimes blackish brown. In its appearance it has a strong resemblance to caoutchouc or Indian rubber; hence its name. Consistency various: sometimes so soft as to adhere to the fingers; sometimes nearly as hard as asphalt. When soft it is elastic; when hard brittle. Sp. gr. 0.9053 to

‡ Hatchett, ibid. 1.0233‡.

Insoluble in alcohol, ether, and oil of turpentine, but soluble in oil of olives. Not affected by nitric acid. When distilled, it yields a bituminous oil insoluble in

* Lametherie, Jour. de Phys. xxxi. 312. alcohol; the residuum is carbonaceous*.

There is a variety of this substance found in a rivulet near the mine of Odin, which, when fresh cut, exactly resembles fine cork in colour and texture; but in a few days after being exposed to the air, becomes of a pale reddish brown. This substance contains within

† Hatchett, ibid. it a nucleus of elastic bitumen. It seems to be the elastic bitumen altered in its texture by the water †.

173 G. IV Coal.

Genus IV. coal.

The substances belonging to this genus are composed of carbon or rather charcoal, and bitumen.

174 Jet.

species 1. Jet (s).

This substance is found in France, Spain, Germany, Britain, and other countries. It is found in detached kidneyform masses, of various sizes, from an inch to seven or eight feet in length.

Colour full black. Lustre 3 to 4; internal glassy. Opaque. Hardness 7 to 8. Not near so brittle as asphalt. Texture striated. Fracture conchoidal. Sp.

* Brisson. gr. 1.259*. It has no odour except when heated, and then it resembles the odour of asphaltum. Melts in a strong heat, burns with a greenish flame, and leaves an

† Hatchett. earthy residuum†.

‡ Kirwan. Becomes somewhat electric by friction ‡. When

§ Vauquelin. distilled yields a peculiar acid §.

This mineral is formed into buttons, beads, and other

‖ Jour. de Min. N° iv. 41. trinkets. The manufacture has been almost confined to France ‖.

175 Cannel coal.

species 2. Cannel coal.

This mineral is found in Lancashire, and in different parts of Scotland, where it is known by the name of *parrot coal*.

Colour black. Lustre common, 2. Opaque. Structure sometimes slaty. Texture compact. Fracture conchoidal. Hardness 5 to 8. Brittle. Sp. gr. 1.232 to 1.426. Does not stain the fingers.

Kindles easily, and burns with a bright white flame like a candle (T), which lasts but a short time. It does not cake. It leaves a stony or sooty residuum.

A specimen of Lancashire cannel coal, analysed by Mr Kirwan, contained

75.20 charcoal,
21.68 maltha,
3.10 alumina and silica.

99.98†

† Mineral. ii. 523.

A specimen of the slaty kind from Ayrshire, called *splent coal*, was composed of — Combustibles.

47.62 charcoal,
32.52 maltha,
20.00 earths.

100.14‡

‡ Ibid. 524.

Cannel coal is susceptible of polish, and, like jet, is often wrought into trinkets.

176 Common coal.

species 3. Common coal.

This very useful combustible is never found in the primitive mountains, but only in the secondary mountains, or in plains formed of the same materials with them. It is always in strata, and generally alternates with clay, sandstone, or limestone.

Colour black, more or less perfect. Lustre usually greasy or metallic, 2 to 4. Opaque. Structure generally slaty. Texture often foliated. Fracture various. Hardness 4 to 6. Sp. gr. 1.25 to 1.37. Usually stains the fingers. Takes fire more slowly, and burns longer, than the last species. Cakes more or less during combustion.

Of this species there are many varieties, distinguished in Britain by the names of caking coal, rock coal, &c. These are too well known to require any description.

Mr Kirwan analysed a variety of different kinds of coal: The result of his experiments may be seen by the following table.

Whitehaven coal.	Wigan	Swansey	Leitrim	
57.0	61.73	73.53	71.43	charcoal.
41.3	36.7	23.14	23.37	maltha & asph
1.7	1.57	3.33	5.20	earths ‡.
100.0	100.00	100.00	100.00	

‡ Mineral. ii. 525.

177 Spurious coal.

species 4. Spurious coal.

This mineral is generally found amidst strata of genuine coal. It is also called *parrot coal* in Scotland.

Colour greyish black. Lustre 0 to 1. Structure usually slaty. Texture earthy. Hardness 7 to 8. Sp. gr. 1.5 to 1.6. Generally explodes, and bursts when heated.

Composed of charcoal, maltha, and asphalt, and above .20 of stony matter.

178 G. V. Amber.

Genus V. amber.

species 1. Common amber.

This substance, called *electrum* by the ancients, is found in different countries; but most abundantly in Prussia, either on the sea shore, or under ground at the depth of about 100 feet, reposing on *wood coal**. It

* Kirw. Min. ii. 66. is in lumps of different sizes.

Colour yellow. Lustre 3 to 2. Transparency 2 to 4. Fracture conchoidal. Hardness 5 to 6. Sp. gr. 1.078 to 1.085. Becomes electric by friction.

If a piece of amber be fixed upon the point of a knife, and then kindled, it burns to the end without melting †.

By distillation it yields succinic acid.

(s) It was called *gagathes* by the ancients, from the river Gages in Licia, [illegible] which it was found [illegible] French, *azabache* in Spanish, *gagath* in German.

(T) Hence it has been called *cannel coal*. *Candle*, in the Lancashire and Scotch dialect, [illegible] *cannel*.

Class IV. METALLIC ORES.

This class comprehends all the mineral bodies, composed either entirely of metals, or of which metals constitute the most considerable and important part. It is from the minerals belonging to this class that all metals are extracted; for this reason they have obtained the name of *ores*.

179 Orders. The metals hitherto discovered amount to 21; we shall therefore divide this class into 21 orders, allotting a distinct order for the ores of every particular metal.

Metals exist in ores in one or other of the four following states. 1. In a metallic state, and either solitary or combined with each other. 2. Combined with sulphur. 3. In the state of oxyds. 4. Combined with acids. Each order therefore may be divided into the four following genera.

180 Genera

1. Alloys.
2. Sulphurets.
3. Oxyds.
4. Salts.

It must be observed, however, that every metal has not hitherto been found in all these four states, and that some of them are hardly susceptible of them all. Some of the orders therefore want one or more genera, as may be seen from the following table.

Order I. *Gold ores.*
 1. Alloys.
Order II. *Silver ores.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
 4. Salts.
Order III. *Platinum ores.*
 1. Alloys.
Order IV. *Ores of mercury.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
 4. Salts.
Order V. *Copper ores.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
 4. Salts.
Order VI. *Iron ores.*
 1. Alloys.
 2. Sulphurets.
 3. Carburets.
 4. Silicated iron.
 5. Oxyds.
 6. Salts.
Order VII. *Tin ores.*
 1. Sulphurets.
 2. Oxyds.
Order VIII. *Lead ores.*
 1. Sulphurets.
 2. Oxyds.
 3. Salts.
Order IX. *Zinc ores.*
 1. Sulphurets.
 2. Oxyds.
 3. Salts.
Order X. *Antimonial ores.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
 4. Salts.
Order XI. *Bismuth ores.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
Order XII. *Arsenic ores.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
Order XIII. *Cobalt ores.*
 1. Alloys.
 2. Sulphurets.
 3. Oxyds.
 4. Salts.
Order XIV. *Nickel ores.*
 1. Sulphurets.
 2. Oxyds.
 3. Salts.
Order XV. *Manganese ores.*
 1. Oxyds.
 2. Salts.
Order XVI. *Tungsten ores.*
 1. Oxyds.
 2. Salts.
Order XVII. *Ores of molybdenum.*
 1. Sulphurets.
Order XVIII. *Ores of uranium.*
 1. Oxyds.
 2. Salts.
Order XIX. *Ores of titanium.*
 1. Oxyds.
Order XX. *Ores of tellurium.*
 1. Alloys.
Order XXI. *Ores of chromum.*
 1. Oxyds.

Order I. GOLD ORES.

No metal perhaps, if we except iron, is more widely scattered through the mineral kingdom than gold *. Hitherto it has been found only in a metallic state; most commonly in grains, ramifications, leaves, or rhomboidal, octohedral, or pyramidal crystals. It is generally mixed with quartz, though there are instances of its having occurred in calcareous rocks. It is not uncommon also to find it disseminated through the ores of other metals; especially iron, mercury, copper, and zinc. The greatest quantity of gold is found in the warmer regions of the earth. It abounds in the sands of many African rivers, and is very common in South America and India. Europe, however, is not destitute of this metal. Spain was famous in ancient times for its gold mines, and several of the rivers in France contain it in their sands †. But the principal gold mines in Europe are those of Hungary, and next to them those of Salzburg. Gold also has been discovered in Sweden and Norway, and more lately in the county of Wicklow in Ireland ‡. 181 Where found.

* Bergman.

† Reaumur, Mem. Par. 1718, p. 68.

‡ Lloyd, Phil. Trans. 1790, p. 36. Mills, ibid. p. 38.—Nicholson's Journ. ii. 224.

Genus I. Alloys of gold.

Species 1. Native gold.

182 G. I. Native gold.

Native gold is never completely pure; it is alloyed with some silver or copper, and sometimes with iron. In the native gold found in Ireland, indeed, the quantity of alloy appears to have been exceedingly small.

Its colour is yellow. Lustre metallic. Fracture hackly. Hardness 5. Sp. gr. from 12 to 19.

Order II. SILVER ORES.

Silver is found most commonly in quartz, limestone, hornstone; or combined with the ores of other metals, most commonly with copper, antimony, zinc, cobalt, and lead. This last metal indeed is seldom totally destitute of silver. 183 Where found.

Genus I. Alloys of silver.

Species 1. Native silver *.

184 G. I. Native silver.

Native silver, so called because the silver is nearly in a state of purity, forms the principal part of some of the richest silver mines in the world. It is sometimes in small lumps; sometimes crystallized in cubes, hexahedrons, octohedrons, or dodecahedrons; sometimes in leaves, or threads, often so connected with each other as to resemble branches of trees, and therefore called *dendrites*. The silver in the famous mines of Potosi has this last form. When newly extracted, it is not unlike small branches of fir †.

The colour of native silver is white; often tarnished. Lustre metallic. Fracture hackly. Hardness 6. Malleable. Sp. gr. from 10 to 10.338.

The silver in this species is almost constantly alloyed with from .03 to .05 of some other metal, frequently gold or arsenic.

* Kirw. ii. 108.—Collings. Act. Liter. Svecia, 1738, p. 440.

† Bergman's Phys. Geogr. Jour. de Min. No xvi. p. 26.

Silver

185 Alloy of silver and gold.

SPECIES 2. Alloy of silver and gold.

Auriferous native silver.

This alloy is not uncommon in silver mines. Its colour is yellowish white. Its lustre metallic. Hardness 5. Malleable. Sp. gr. above 10.6. Dr Fordyce found a specimen from Norway composed of

72 silver,
28 gold.

100*

* *Phil. Trans.* 1776, p 532.

SPECIES 3. Alloy of silver and antimony †.

Antimoniated silver ore.

186 Alloy of silver and antimony. This alloy, which is found in the silver mines of Spain and Germany, is sometimes in grains or lumps, and sometimes crystallized in six-sided prisms, whose sides are longitudinally channelled ‡.

Its colour is white. Its lustre metallic. Hardness 10. Brittle. Sp. gr. from 9.4406 § to 10||. Texture foliated. Fracture conchoidal. Before the blow-pipe the antimony evaporates in a grey smoke, and leaves a brownish slag, which tinges borax green. If borax be used at first, a silver bead may be obtained.

This alloy was long supposed to contain arsenic. Bergman examined it, and found only silver and antimony ¶. His analysis has been confirmed by the experiments of Vauquelin and Selb *. According to Selb, it is composed of 89 silver,

11 antimony.

100

A specimen, analysed by Klaproth, contained

84 silver,
16 antimony.

100

Another specimen contained

76 silver,
24 antimony.

100 †

† Kirwan, ii. 110.

§ Haüy, Jour. de Min. N° xxx p 473.
|| Kirwan, ibid.
¶ Opusc. ii 415.
* Jour. de Min. ibid
† Beiträge, ii. 301.

GENUS II. SULPHURETS OF SILVER.

187 G. II. Sulphurets. Common sulphuret of silver.

SPECIES 1. Common sulphuret of silver ‡.

Vitreous silver ore.

This ore occurs in the silver mines of Germany and Hungary. It is sometimes in masses, sometimes in threads, and sometimes crystallized. Its crystals are either cubes or regular octohedrons, whose angles and edges are often variously truncated. For a description of the varieties produced by these truncatures, we refer the reader to *Romé de Lisle* ¶.

Its colour is dark bluish grey, inclining to black; often tarnished. Internal lustre metallic. Texture foliated. Fracture uneven. Hardness 4 to 5. May be cut with a knife like lead. Flexible and malleable. Sp. gr. 6 909* to 7.215 †. In a gentle heat the sulphur evaporates. Melts when heated to redness.

A specimen of this ore, analysed by Klaproth, contained

85 silver,
15 sulphur.

100 ‡

‡ Kirwan, ii. 115.
¶ Crystal. 441.
* Brisson.
† Gellert.
‡ Beiträge, i. 162.

SPECIES 2. Antimoniated silver ore *.

Sulphuret of silver with antimony and iron.

188 Antimoniated silver ore. This ore, which occurs in Saxony and Hungary, seems to be sulphuret of silver contaminated with antimony and iron, and ought therefore, in all probability, to be considered merely as a variety of the last species. It is sometimes in masses, but more frequently crystallized in six-sided prisms, tables, or rhomboids; generally indistinct and accumulated together.

Its colour is iron grey; often tarnished. Its lustre metallic. Fracture uneven. Hardness 4 to 5. Brittle. Sp. gr. 7.208 †. Before the blow pipe the sulphur and antimony exhale, leaving a bead, which may be freed from iron by fusion with nitre and borax.

A specimen of this ore, analysed by Klaproth, contained

66.5 silver,
12.0 sulphur,
10.0 antimony,
5.0 iron,
1.0 silica,
0.5 arsenic and copper.

95.0 ‡

* Kirwan, ii. 118.
† Gellert.
‡ Beiträge, i. 160.

SPECIES 3. Sulphuret of silver and copper *.

Cupriferous sulphurated silver ore.

189 Sulphuret of silver and copper. This ore, which is found in the Korbolokinsk mountains in Siberia, was first described by Mr Renovantz. It is in amorphous masses, varying in size from that of the thumb to that of the fist.

Its colour is bluish grey like lead. Lustre metallic. Hardness 5 to 6. Brittle. Its powder, when rubbed on the skin, gives it a black colour and a leaden gloss. Before the blow-pipe the sulphuret of silver melts readily; that of copper with difficulty. This ore is composed of about

42 silver,
21 copper,
35 sulphur.

98

* Kirwan, ii. 121.

GENUS III. OXYDS OF SILVER.

190 G. III. Oxyds. Calciform silver ore.

SPECIES 1. Calciform silver ore †.

This ore was first described by Mr Widenman. It is sometimes in masses, sometimes disseminated through other minerals.

Its colour is greyish black. Its streak bright. Its lustre metallic. Its fracture uneven. Hardness 4 to 5. Brittle. Sp. gr. considerable. Effervesces with acids. Melts easily before the blow-pipe. Froths with borax.

According to Selb, it contains 72.5 silver,

15.5 copper,
12.0 carbonic acid.

100.0

† Kirwan, ii. 112.

SPECIES 2. Red silver ore (v).

191 Red silver ore. This ore is very common in several German silver mines. It occurs in masses, disseminated and crystallized. The primitive form of its crystals is a dodecahedron ‡, whose sides are equal rhombs, and which may be con-

‡ Fig. 38.

(v) *Kirw.* II. 122.—*Scopoli de Minera Argenti Rubra.*—*Sage*, *Jour. de Phys.* XXXIV. 331. and XLI. 370; and *Nouv. Jour. de Phys.* II. 284.—*Westrum*, *Jour. de Phys.* XLIII. 291.—*Klaproth*, *Beiträge*, I. 141.

Silver. considered as a six sided rhomboidal prism, terminated by three sided summits *. Sometimes the prism is lengthened, and sometimes its edges, or those of the terminating summits, or both, are wanting. For a description and figure of these varieties, we refer to *De Lisle* † and *Hauy* ‡.

Its colour is commonly red. Streak red. External lustre metallic, internal common. Transparency from 3 to 1; sometimes opaque. Fracture flat conchoidal. Hardness 5 to 7. Brittle. Sp. gr. from 5.44 § to 5.592 ¶. Becomes electric by friction, but only when insulated ‖. Soluble in nitric acid without effervescence *. Before the blow pipe melts, blackens, burns with a blue flame, gives out a white smoke with a slight garlic smell, and leaves a silver bead †.

Variety 1. Light red.

Colour intermediate between blood and cochineal red; sometimes variegated. Streak orange red. Powder black.

Variety 2. Dark red.

Colour commonly between dark cochineal red and lead grey; sometimes nearly black and without any shade of red. Streak dark crimson red.

This ore was long supposed to contain arsenic. Klaproth first ascertained its real composition ‡; and his analysis has been confirmed by Vauquelin, who found a specimen composed of 56.6748 silver,

16.1300 antimony,
15.0666 sulphur,
12.1286 oxygen.

100.

Klaproth proved, that the silver and antimony are in the state of oxyds; and Vauquelin, that the sulphur is combined partly with the oxyd of silver and partly with the oxyd of antimony. Klaproth obtained a little sulphuric acid; but this acid, as Vauquelin, with his usual ingenuity, demonstrated, was formed during the analysis.

This ore sometimes contains a minute portion of arsenic, but never more than .02 *.

GENUS IV. SALTS OF SILVER.

SPECIES 1. Muriat of silver (x).

Corneous silver ore.

192 G. IV. Salts. Muriat of silver. This ore occurs at Johanngeorgenstadt in Saxony, in South America, &c. It is often amorphous, sometimes nearly in powder, and sometimes crystallized in cubes or parallelopipeds.

Its colours are various: when exposed to the light it becomes brown. Internal lustre greasy, 2; external, 2 to 1. Acquires a gloss when scraped with a knife. Transparency 2 to 1. Texture foliated. Hardness 4 to 5. Sp. gr. 4.745 * to 4.804 †. Before the blow-pipe it instantly melts, and gradually evaporates, but may be reduced by adding an alkali.

* Prisson.
† Gellert.

Metallic ores

That this ore contains muriatic acid, has been long known. Mr Woulfe first shewed that it contained also sulphuric acid ‡: and this discovery has been confirmed by Klaproth, according to whose analysis this ore is composed of

67.75 oxyd of silver,
6.00 oxyd of iron,
21.00 muriatic acid,
.25 sulphuric acid,
1.75 alumina.

96.75 ¶

The alumina can only be considered as mixed with the ore. Sometimes its quantity amounts to .67 of the whole §.

‡ Phil. Trans. 1776.
¶ Beiträge, i. 134.
§ Ibid. p. 137.

ORDER III. ORES OF PLATINUM (y).

193 Mines. HITHERTO no mine of platinum has been discovered. It is found in small scales or grains on the sands of the river Pinto, and near Carthagena in South America. It is always in a metallic state, and always combined with iron.

GENUS I. ALLOYS OF PLATINUM.

SPECIES 1. Native platinum.

194 G. I. Alloys. Native platinum. Its colour is whitish iron grey. Magnetic. Sp. gr. from 12 to 16. Soluble in nitro-muriatic and oxy-muriatic acids.

ORDER IV. ORES OF MERCURY.

MERCURY is employed in medicine; it serves to separate silver and gold from their ores; the silvering of looking glasses, gilding, &c. are performed by means of it; and its sulphuret forms a beautiful paint.

195 Mines. Mercury abounds in Europe, particularly in Spain, Germany, and Hungary: it is found also in China (z), the Philippines *, and in Peru, and perhaps Chili (A) in South America. The most productive mines of mercury are those of Idria †; of Almaden, near Cordova in Spain, which were wrought by the Romans (B); of the Palatinate ‡; and of Guanca Veliça in Peru (C).

Mercury has never been found in Britain, nor has any mine worth working been discovered in France. It occurs most commonly in argillaceous shistus, limestones, and sandstones.

* Carreri Voyage.
† Scopoli, Jour. de Min. N° xxxvi. p. 915.
‡ Jour. de Min. Nos vi. and vii.

GENUS I. ALLOYS OF MERCURY.

SPECIES 1. Native mercury.

196 G. I. Alloys. Native mercury. Native mercury is found in most mercurial mines: it is in small globules, scattered through different kinds of stones, clays, and ores.

Fluid. Colour white. Sp. gr. about 13.6.

Ores of Mercury.

SPECIES 2. Amalgam of silver *.
Native amalgam.

197 Amalgam of silver. This mineral has been found in the silver mine of Sahlberg †, in the province of Dalecarlia, in Sweden; in the mines of Deux Ponts ‡, in the Palatinate; and in other places. It is in thin plates, or grains, or crystallized in cubes, parallelopipeds, or pyramids.

Its colour is silvery white or grey. Lustre metallic. Creaks when cut. Sp. gr. above 10. Tinges gold white. Before the blow-pipe the mercury evaporates and leaves the silver.

A specimen of this amalgam, analysed by Klaproth, contained 64 mercury,
36 silver.

100 §

Sometimes it contains a mixture of alumina, and sometimes the proportion of mercury is so great that the amalgam is nearly as soft as paste.

* *Kirwan*, ii. 223.
† *Cronstedt's Min.*
‡ *Hever Crell's Annals*, 1790.
§ *Beiträge* i 183.

108 G. II. Sulphurets. Common sulphuret.

GENUS II. SULPHURETS OF MERCURY.
SPECIES I. Common sulphuret *.
Native cinnabar.

This ore, which is found in almost all mercurial mines, is sometimes in veins, sometimes disseminated, sometimes in grains, and sometimes crystallized. The form of its crystals is a tetrahedron or three-sided pyramid, most commonly wanting the summit; sometimes two of these pyramids are joined base to base; and sometimes there is a three-sided prism interposed between them †.

Its colour is red. Its streak red and metallic. Lustre when crystallized 2 to 3; when amorphous, often 0. Transparency, when crystallized, from 1 to 3; when amorphous, often 0. Texture generally foliated. Hardness from 3 to 8. Sp. gr. from 5.419 to 10 1285.

Before the blow-pipe evaporates with a blue flame and sulphureous smell. Insoluble in nitric acid ‡.

Variety 1. Dark red.

Colour cochineal red. Hardness 6 to 7. Sp. gr. when pure, 10.1285 §; sometimes only 7.2, or even 6.188 ¶.

Variety 2. Bright red.

Colour commonly scarlet. Sp. gr. 6.9022 † to 5.419 ‡.

¶ *Muschenbroek.*
† *Brisson.*
‡ *Gellert.*

199 G. III. Oxyds. Hepatic mercurial ore.

GENUS III. OXYDS OF MERCURY.
SPECIES I. Hepatic mercurial ore *.

This ore, which is the most common in the mines of Idria, is always amorphous, and is often mixed with native mercury and cinnabar.

Its colour is somewhat red. Its streak dark red and brighter. Lustre commonly metallic. Hardness from 6 to 8. Sp. gr. from 9.2301 † to 7.186 ‡. When heated the mercury evaporates.

Though this ore has never been accurately analysed, chemists have concluded that the mercury which it contains is in the state of a red oxyd, because it is insoluble in nitric and soluble in muriatic acid ¶. When purest, it contains about .77 of mercury §. It contains also some sulphur and iron.

Werner has divided this species into two varieties, the *compact* and the *slaty*. The second is often nothing more than bituminous shale impregnated with oxyd of mercury †.

* *Kirwan*, ii. 224.
† *Brisson*

§ *Scopoli, Jour. de Min.* N° xxxvi. p 919
† *Kirwan*, ii. 226.

GENUS IV. MERCURIAL SALTS.
SPECIES I. Muriat of mercury *
Corneous mercury.

200 Mercurial salts. Muriat of mercury. This ore, which occurs in the Palatinate, is sometimes in scales, sometimes in grains, and sometimes crystallized. Its crystals are either small four or six sided prisms whose sides are rhombs †, or cubes, or four sided pyramids wanting their angles. They are always very small and generally confused.

Its colours are various; but it is most frequently white. Its lustre, when white, is pearly. Sometimes opaque, and sometimes semitransparent. Evaporates before the blow-pipe.

Mr Woulfe discovered, that this ore generally contains some sulphuric acid ‡. Specimens have been found in which the quantity of sulphuric acid exceeds that of the muriatic §.

† *Jour. de Min.* iii. 161.
‡ [illegible]
§ [illegible]

ORDER V. COPPER ORES.

MANY of the most useful utensils are formed of copper: it enters largely into the composition of brass, bronze, and bell metal; not to mention the dyes and paints of which it is the basis.

201 Mines. Copper mines abound in most countries. They are wrought in China, Japan, Sumatra; the north of Africa; in Chili and Mexico; and in most parts of Europe; especially Britain, Germany, Russia, Hungary.

Copper is found most commonly in rocks of hornblende, shistus, and quartz.

GENUS I. ALLOYS OF COPPER.
SPECIES I. Native copper *.

202 G.I. Alloys. Native copper. Native copper occurs now and then in the greater number of copper mines: Sometimes it is in masses, sometimes in plates and threads, which assume a variety of forms; and sometimes, as in Siberia, it is crystallized in cubes, or other forms nearly resembling cubes †.

Colour commonly that of copper, but sometimes dark brown. Lustre metallic. Streak brighter. Fracture hackly. Flexible and malleable. Hardness 6 to 7. Sp. gr. from 7.6 to 8.5844 ¶.

* *Kirwan*, ii. [illegible]
† *Cronstedt*, [illegible]
¶ *Hauy, Jour. de Min.* N° xxxii. [illegible]

SPECIES 2. White copper ore *.
Alloy of copper, iron, and arsenic.

203 White copper ore. This ore, which is said to be uncommon, occurs in masses. Colour white. Lustre metallic. Fracture uneven. Hardness 8 to 9. Brittle. Sp. gr. considerable.

Before the blow-pipe gives out a white arsenical smoke, and melts into a greyish black slag *.

* *Kirwan's Min.* ii. 152.
* *Wiedeman.*

GENUS II. SULPHURETS OF COPPER.
SPECIES I. Common sulphuret of copper †.
Vitreous copper ore.

204 G. II. Sulphurets. Common sulphuret of copper. This ore, which is found in Cornwall, Hungary, and Siberia, occurs in masses, plates, threads, and crystallized in six-sided prisms, or four sided pyramids, joined base to base.

Colour bluish grey. Streak brighter grey. Lustre metallic. Hardness 4 to 7. Sp. gr. 5.452 to 5.565; sometimes so low as 4.129 *. Detonates with nitre.

Before the blow-pipe it melts easily, and while in fusion exhibits a green pearl, which, on cooling, is covered with a brown crust. Tinges borax green.

Werner makes two varieties of these ores; the first he

† *Kirwan*, ii 134.
* *Kirwan.*

Copper Ores. calls *compact*, from its fracture; and the second, for the same reason, he calls *foliated*. This last is somewhat darker coloured than the first, but in other respects they agree.

205 Copper pyrites

SPECIES 2. Copper pyrites*.
Yellow copper ore.

* Kirwan, ii. 140. This ore, which is probably nothing else than fulphuret of iron combined with copper, and which, therefore, would be more properly placed among iron ores, is found frequently in copper mines, and mixed with common pyrites or fulphuret of iron. It is sometimes amorphous, and sometimes cryftallized. Its cryftals are either three or four fided pyramids applied base to base, or six fided plates.

Its colour is yellow; often tarnished. Its internal lustre metallic. Hardness 6 to 7; sometimes 9. Brittle. Sp. gr. 4.314 † to 4.3 ‡. Deflagrates; but does not detonate with nitre ‖.

† Brisson. ‡ Kirwan. ‖ Id. Min. ii 141.

Before the blow pipe decrepitates, gives a greenish fulphureous smoke, and melts into a black mass, which tinges borax green. Does not effervesce with nitric acid.

206 Purple copper ore.

SPECIES 3. Purple copper ore*.

* Kirwan, ii. 142. This ore is found in masses, or plates, or disseminated; sometimes, also, it is cryftallized in octohedrons. Colour various, but most commonly purple; internally reddish. Streak reddish and bright. Lustre metallic. Hardness 6 to 7. Brittle. Sp. gr. 4.956 to 4.983†.

† Id. ii. 143.

Effervesces with nitric acid, and tinges it green. Deflagrates with nitre. Before the blow-pipe melts readily, without smoke, vapour, or smell; but is not reduced. Tinges borax a bright green.

A specimen of this ore, analysed by Klaproth, contained

58	copper,
18	iron,
19	sulphur,
5	oxygen.
100 ‡	

‡ Beiträge, ii. 286.

207 Grey copper ore

SPECIES 4. Grey copper ore §.

§ Kirwan, ii 146. This ore is found in Cornwal, Saxony, Hungary, &c. It is often amorphous, but often also cryftallized. The primitive form of its cryftals is the regular tetrahedron, but, in general, either the angles or the edges, or both, are truncated or bevelled ‖.

‖ Romé de Lisle, iii. 315

Colour steel grey; often tarnished, and then dark grey. Streak dark grey; sometimes reddish brown. Powder blackish; sometimes with a tint of red. Lustre metallic. Hardness 7 or 8. Very brittle. Sp. gr. 4.8648 *. Deflagrates with nitre. Before the blowpipe crackles, but at last melts, especially if assisted by borax. The bead gives a white smoke, without any particular smell; tinges borax yellow or brownish red, but does not unite with it.

* Hauy, Jour. de Min. N° xxxi. 512.

A specimen of this ore from Cremnitz, analysed by Klaproth, contained

31	copper,
14	silver,
34	antimony,
3	iron,
11	sulphur.

Napion, in an ore from the valley of Lanzo, found copper, silver, and antimony, nearly in the same proportions, but more iron, and some arsenic †. Savoresi, as Baron Born informs us, besides the ingredients of Klaproth's analysis, found some gold and mercury in grey copper ore ‡: and Klaproth himself found lead in most of the other specimens which he examined.

† Mem Turin, v. 173.

‡ Catal. ii. 498.

208 G. III. Oxyds. Red oxyd of copper.

GENUS III. OXYDS OF COPPER.

SPECIES 1. Red oxyd of copper §.
Florid red copper ore—Red copper glass.

This ore is found in Cornwal, and many other countries. It occurs in masses, disseminated, in scales, and cryftallized. The figure of its cryftals is most commonly the regular octohedron *.

§ Kirwan, ii 135.

* Hauy, Jour. de Min N° xxxi. 517.

Colour commonly cochineal red. Streak brick red. Lustre semimetallic. Transparency, when amorphous, generally 0; when cryftallized, 3 or 4. Hardness from 4 to 7. Soluble with effervescence in nitric acid. Before the blow pipe melts easily, and is reduced.

This ore was supposed to be composed of carbonic acid and red oxyd of copper; but a specimen, examined by Vauquelin, which consisted of pure cryftals, contained no acid †. It must therefore be considered as an oxyd of copper.

† Ibid.

Werner has made three varieties of this ore, which, from their texture, he has denominated *compact*, *foliated*, and *fibrous*. The first is seldom or never found cryftallized, and is opaque; the second occurs amorphous, cryftallized, and in scales; the third is carmine, ruby, or scarlet red; and occurs always in short capillary cryftals, or delicate flakes.

This ore sometimes contains a mixture of red oxyd of iron; it is then called *brick red copper ore*, *copper malm*, or *copper ochre*.

This ore is sometimes mixed with bitumen. Its colour is then brownish black, and it is called *pitch ore*.

209 Green oxyd of copper.

SPECIES 3. Green oxyd of copper §.
Green sand of Peru.

§ Kirwan, ii. 149.

This ore, which was brought from Peru by Dombey, is a grass green powder, mixed with grains of quartz. When thrown on burning coals, it communicates a green colour to the flame. It is soluble both in nitric and muriatic acids without effervescence. The solution is green. It was supposed to contain muriatic acid *; but Vauquelin has discovered, that the appearance of this acid was owing to the presence of some common salt, which is accidentally mixed with the sand ‡.

* Berthollet, Mem. Par. 1786, 462.

‡ Jour de Min. N° xxxi. 519.

210 G. IV Salts. Blue carbonat of copper.

GENUS IV. SALTS OF COPPER.

SPECIES 1. Blue carbonat of copper (D).
Mountain blue—Azur de cuivre—Blue calx of copper—Kupfer lazur.

This ore, which occurs in the copper mines of Siberia, Sweden, Germany, Hungary, Cornwal, &c. is either amorphous or cryftallized. The cryftals are small, and difficult to examine. According to Romé de Lisle, their primitive form is an octohedron, the sides of which are isosceles triangles, and two of them more inclined than the others §. Be that as it may, the cryftals of blue carbonat of copper are often rhomboidal prisms, either regular, or terminated by dihedral summits *.

§ Cryftal. iii. 343

* Ibid p. 345.

Its colour is azure or smalt blue. Streak blue. Hardness

(D) *Kirw.* II. 129.—*Morveau*, *Mem. Dijon*, 1782. 1 *Semestre*, p. 100.

Copper Ores. Brazil. nefs 4 to 6. Brittle. Sp. gr. 3.608 ‡. It effervefces with nitric acid, and gives it a blue colour. Before the blow-pipe it blackens, but does not melt. Tinges borax green with effervefcences.

The cryftals, according to Pelletier, are compofed of

66 to 70 copper,
18 — 20 carbonic acid,
8 — 10 oxygen,
2 — 2 water.

Fontana firft difcovered that this ore contained carbonic acid gas

Variety 1. Earthy blue carbonat.

Mountain blue.

This variety generally contains a mixture of lime. It is never cryftallized; and fometimes is almoft in the ftate of powder. Luftre 0. Texture earthy.

Variety 2. Striated blue carbonat of copper.

Luftre glaffy. Tranfparency, when cryftallized, 2; when amorphous, 1. Texture ftriated; fometimes approaching to the foliated.

211 Green carbonat of copper. SPECIES 2. Green carbonat of copper (E).

Oxygenated carbonat of copper—Malachite.

This ore is generally amorphous, but fometimes it is cryftallized in four-fided prifms, terminated by four-fided pyramids.

Colour green. Luftre filky. Hardnefs 5 to 7. Brittle. Sp. gr 3.571 * to 3.653 ‡. Effervefces with nitric acid, and gives a blue colour to ammonia. Before the blow pipe it decrepitates and blackens, but does not melt. Tinges borax yellowifh green. It is compofed of carbonic acid and green oxyd of iron.

* Briffon. ‡ Kirwan.

Variety 1. Fibrous malachite.

Texture fibrous. Opaque when amorphous; when cryftallized its tranfparency is 2. Colour generally grafs green.

Variety 2. Compact malachite.

Texture compact. Opaque. Colour varies from the dark emerald green to blackifh green.

A fpecimen of malachite from Siberia, analyfed by Klaproth, contained

58.0 copper,
18.0 carbonic acid,
12.5 oxygen,
11.5 water.

100 *

* Beitrüge, 290.

This fpecies is fometimes mixed with clay, chalk, and gypfum, in various proportions; it is then known by the name of

Common mountain green.

Its colour is verdigris green. Luftre 0. Tranfparency 0 to 1. Hardnefs 3 to 4. Brittle. Texture earthy. Effervefces feebly with acids. Before the blow-pipe it exhibits the fame phenomena with malachite.

212 Sulphat of copper. SPECIES 3. Sulphat of copper.

For a defcription of this falt, fee CHEMISTRY, n° 648. in this *Supplement.*

213 Arfeniat of copper. SPECIES 4. Arfeniat of copper ‡.

Olive copper ore.

This ore is found at Carrarach in Cornwal. It is generally cryftallized in fix-fided compreffed prifms. Its colour is olive green. Streak fometimes ftraw coloured, fometimes olive green. Luftre glaffy. Tranfparency from 4 to 2. Fracture conchoidal. Hardnefs 4 to 7. Before the blow pipe deflagrates with an arfenical fmoke, and melts into a grey coloured bead. This bead, fufed with borax, leaves a button of pure copper ‖.

‡ Kirwan, 151.

Metallic Ores.

Klaproth difcovered that it was compofed of oxyd of copper and arfenic acid.

‖ Klaproth's Obfervations on Cornwal, p. 29.

Sometimes this ore is combined with iron. It then cryftallizes in cubes. Thefe cubes are of a dark green colour; before the blow pipe they froth, give out an arfenical fmoke, and do not fo quickly form a grey bead as the arfeniat of copper *.

* Ibid. p. 29.

ORDER VI. IRON ORES.

To defcribe the ufes of iron, would be to write the hiftory of every art and manufacture, fince there is not one which is not more or lefs dependent upon this ufeful metal. Nor is its abundance inferior to its utility. It exifts almoft everywhere, and feems, as it were, the bond which connects the mineral kingdom together. 214 Iron.

GENUS I. ALLOYS OF IRON

215 G. I. Alloys. Native iron.

SPECIES 1. Native iron (F).

Native iron has been found in Siberia and in Peru in immenfe maffes, which feemed as if they had been fufed. Thefe maffes evidently did not originate in the place where they were found. See *Fire-Balls, Suppl.*

Colour bluifh white Fracture hackly Luftre metallic. Malleable. Magnetic Hardnefs 8 to 9. Sp. gr. 7.8. Prouft has difcovered, that the native iron found in Peru is alloyed with nickel ¶.

¶ Nicholfon's Jour. III. 374.

GENUS II. SULPHURETS OF IRON.

SPECIES 1. Common fulphuret of iron *.

Pyrites.

216 G. II. Sulphurets. Common fulphuret of iron.

This mineral occurs very frequently both in ores and mixed with other bodies, for inftance in flates. It is often amorphous, and often alfo cryftallized. The primitive form of its cryftals is either a regular cube or an octohedron. The varieties of its form hitherto defcribed amount to 30; for a defcription of which we refer the reader to *Rome de l'Ifle* †.

* Kirwan, ii 76.—Henkel's Pyritology.

Its colour is yellow. Its luftre metallic. Hardnefs 8 to 10. Brittle Sp gr. 3.44 to 4.6. Soluble in nitric acid with effervefcence. Scarce foluble in fulphuric acid. Before the blow-pipe burns with a blue flame and a fulphureous fmell, and leaves a brownifh bead, which tinges borax of a fmutty green.

Variety 1. Common pyrites.

Fracture uneven Hardnefs 10. Decrepitates when heated. Emits a fulphureous fmell when rubbed Not magnetic. It occurs often in coal mines and in flates.

Variety 2. Striated pyrites.

Texture ftriated. Hardnefs 10. Not magnetic.

Variety 3. Capillary.

Colour often fteel grey. Found in needle-form cryftals. Uncommon. Not magnetic.

Variety 4. Magnetic pyrites.

Found in maffes. Texture compact. Hardnefs 8, 9. Slightly magnetic. Seems to contain lefs fulphur than the other varieties.

In pyrites the proportion of the fulphur to the iron is variable, and this explains the variety of its cryftalline forms.

GEN

(E) *Kirw* II. 131.—*Fontana, Jour. de Phyf.* XI. 509.—*Klaproth, Beiträge,* II. 287.

(F) *Pallas, Phil. Tranf.* LXVI. 523.—*Rubin de Celis, ibid.* LXXVIII. 37.—See alfo *Schreiber, Jour. de Phyf.* XLI. 3.; and *Stelin, Phil. Tranf.* LXIV. 461.

Iron Ore.

GENUS III. CARBURET OF IRON.

217 G. III. Plumbago.

SPECIES 1. Plumbago *.

Graphite of Werner.

* Kirwan, i. 155.

This mineral is found in England, Germany, France, Spain, America, &c. It occurs in kidney form lumps of various sizes. Its colour is dark iron grey or brownish black; when cut, bluish grey. Lustre metallic, from 3 to 4. Opaque. Structure scaly. Texture fine grained. Hardness 4 to 5. Brittle. Sp. gr. from 1.987 to 2.089; after being soaked in water 2.15; after being heated 2.3, and when heated after that 2.41†. Feels somewhat greasy. Stains the fingers, and marks strongly. The use of this mineral when manufactured into pencils is known to every person.

† Brisson.

Its composition was discovered by Scheele. When pure it contains
90 carbon,
10 iron.

100

But it is often exceedingly impure: A specimen, for instance, from the mine of Pluflier, in France, analysed by Vauquelin, contained
23 carbon,
2 iron,
38 silica,
37 alumina.

100 ‡

‡ Jour. de Min. No xii. p. 16.

GENUS IV. IRON COMBINED WITH SILICA.

218 G. IV. Emery.

SPECIES 1. Emery *.

* Kirwan, ii. 193.

This mineral is commonly disseminated through other fossils, but sometimes in the East Indies it occurs in large masses.

Its colour is bluish grey, greyish brown, or bluish black, often covered with a yellowish rind; internally it discovers red or purple spots. Lustre 1 or 0; in some parts 2, and metallic. Opaque. Hardness 14. Brittle. Sp. gr. 3.92†. Before the blow pipe it blackens and gives a smutty yellow tinge to borax.

† Wiegleb.

According to Wiegleb it contains
95.6 silica,
4.3 iron.

99.9

GENUS V. OXYDS OF IRON.

This genus is very extensive: for iron is much more frequently found in the state of an oxyd than in any other.

219 Black oxyd of iron.

SPECIES 1. Black oxyd of iron ‡.

‡ Kirwan, ii. 158.

Common magnetic iron stone—Blackish octohedral iron ore.

This species of ore is very common in Sweden; it is found also in Switzerland, Norway, Russia, &c. It occurs in masses, plates, grains, and crystallized. The primitive form of its crystals is a regular octohedron ‡. Sometimes two opposite sides of the pyramids are trapeziums, which renders the apex of the pyramids cuneiform. Sometimes the crystals pass into rhomboidal parallelopipeds, and into dodecahedrons with rhomboidal faces §.

‡ Romé de Lisle, iii. 178.

§ Ibid.

* Hauy, Jour. de Min. No xxviii. 652.

Its surface is brownish black; internally bluish grey. Powder black *. Streak bluish grey, brighter. Lustre metallic. Hardness 9 to 10. Brittle. Sp. gr. from 4.094 to 4.038†. Attracted by the magnet, and generally possessed of more or less magnetic virtue ‡. To this species belongs the magnet. Before the blow-pipe it becomes browner, but does not melt. Tinges borax dark green.

† Kirwan's Min. i. 50.

‡ Hauy, Jour. de Min. No xxiii. 523.

Metallic Ores.

When pure it consists entirely of oxyd of iron; and this oxyd appears to contain from .15 to .24 oxygen, and from .76 to .85 iron §. Undoubtedly it consists of a mixture of iron in two different states of oxydation. It is often also mixed and contaminated with foreign ingredients.

§ Kirwan's Min. ii. 159.

There are two varieties of this ore. The first is what we have just described; the second is in the form of sand, and has therefore been called

Magnetic sand *.

* Kirwan, ii.—Dupuget, Jour. de Min. No xxi. p 75.

This substance is found in Italy, Virginia, St Domingo, the East Indies, and in the sand of the river Don at Aberdeen in Scotland. It is black, very hard, magnetic. Sp. gr. about 4.6. Not altered by the blowpipe *per se*; melts into a black glass with potass, and into a green glass with microcosmic salt, both opaque†. It probably contains some silica, as Kirwan has supposed ‡.

† Fourcroy, Ann. de Chim. ii. 127.

‡ Min. ii. 161.

221 Specular iron ore.

SPECIES 2. Specular iron ore ¶.

Fer oligiste.

¶ Kirw. ii. 162.—Coudrai, Jour. d. Phys. iv. 52.

This ore is found abundantly in the isle of Elba near Tuscany. It is either in masses or crystallized. The primitive form of its crystals, and of its integrant molecules, is the cube *. The varieties hitherto observed amount to 7. These are the rhomboidal parallelopiped; the cube, with three triangular faces instead of two of its angles diagonally opposite; two six-sided pyramids, applied base to base, wanting the summits ‡, and sometimes the angles at the bases, and sometimes the alternate edges of the pyramid; a polyhedron of 24 sides, resembling a cube with three triangular faces for two angles diagonally opposite, and two triangles for the rest of its angles. For a description and figure of these varieties, we refer to *Romé de Lisle*† and *Hauy*†.

* Hauy, Jour. de Min. No xxxiii. 660.

‡ Fig. 39.

† Cryst. iii. 189.

† Ibid. 660.

Colour steel grey; often tarnished, and beautifully iridescent, reflecting yellow, blue, red. Streak red. Powder dark red. Lustre metallic. Hardness 9 to 10. Not brittle. Sp. gr. 5.0116† to 5.218‡. Slightly magnetic. Little altered by the blow-pipe. Tinges borax an obscure yellow.

† Hauy.

‡ Brisson.

This ore, according to Mr Mushet, is composed of
66.1 iron,
21.2 oxygen,
10.7 water and carbonic acid,
2.0 lime.

100.0 †

† Phil. Mag. iii. 354.

The quantity of oxygen here stated is probably too small, owing to the unavoidable inaccuracy which results from the *dry way* of analysis which Mr Mushet followed.

Micaceous iron ore

Is generally considered as a variety of this species. Kirwan, however, supposes it to contain carbon, and to be a distinct species.

It is found in Saxony, and in the isle of Elba, &c. generally in amorphous masses, composed of thin six-sided laminae. Colour iron grey. Streak bluish grey. Lustre metallic. Opaque. Feel greasy. Hardness 5 to 7. Brittle. Sp. gr. from 4.5 to 5.07. Slightly magnetic.

Iron Ores.

magnetic. Infusible by the blow-pipe. Tinges borax greenish brown.

222 Laminated specular iron ore.

SPECIES 3. Laminated specular iron ore.

Fer pyrocite of Hauy.

This ore, which is found at Mont d'or in Auvergn, was usually arranged under the last species; but has been separated from it, we think properly, by Mr Hauy, because the form of its crystals is incompatible with the supposition that their primitive nucleus is a cube, as we have seen is the case with common specular iron ore. Its crystals are thin octagonal plates, bounded by six linear trapeziums, alternately inclined different ways†.

Colour steel grey. Powder reddish black. Lustre metallic; surface polished. Fracture glassy. Very brittle ‡. Hauy supposes that this ore has been produced by fire, and accordingly has given it a name which denotes its origin.

† De Lisle, iii. 103.

‡ Hauy, Jour. de Min. N° xxxi. 33.

223 Brown iron ore.

SPECIES 4. Brown iron ore ¶.

This species of ore is found abundantly in Britain, particularly in Cumberland and Lancashire; and it is also very common in other counties. It consists of the brown oxyd of iron, more or less contaminated with other ingredients.

¶ Kirw. ii 163.

Its colour is brown. Its streak reddish brown. Sp. gr. from 3.4771 to 3.951. Before the blow pipe blackens, but does not melt. Tinges borax greenish yellow.

Variety 1. Brown hæmatites.

The name hæmatites (bloodstone) was probably applied by the ancients only to those ores which are of a red colour, and have some resemblance to clotted blood; but by the moderns it is applied to all the ores of iron which give a reddish coloured powder, provided they be of a fibrous texture.

Brown hæmatites occurs in masses of various shapes, and it is said also to have been found crystallized in five or six sided acute angled pyramids. Colour of the surface brown or black, sometimes iridescent; internally nut brown. Powder red. Texture fibrous. Hardness 8 to 10. Brittle. Sp. gr. 3.789† to 3.951‡. Not magnetic.

† Gellert. ‡ Kirwan.

This variety has not been analysed, but it seems to consist of brown oxyd of iron, oxyd of manganese, and alumina ¶.

¶ Kirwan's Min. ii. 164.

Variety 2. Compact brown iron stone.

This variety occurs in masses of very various and often fantastical shapes.

Colour brown. Internal lustre metallic. Texture compact. Hardness 6 to 9. Brittle. Sp. gr. 3.4771† to 3.551‡.

† Brisson. ‡ Kirwan.

Variety 3. Brown Scaly iron ore.

This variety is generally incumbent on other minerals. Colour brown. Lustre metallic. Stains the fingers, marks strongly. Feels unctuous. Texture foliated. Hardness 3 to 5. Brittle. So light as often to float on water.

Variety 4. Brown iron ochre.

This variety occurs both massive and disseminated. Colour from nut brown to orange. Lustre 0. Strongly stains the fingers. Texture earthy. Hardness 3 to 4. When slightly heated reddens.

224 Red iron ore.

SPECIES 5. Red iron ore†.

† Kirw. ii. 168.

Colour red. Streak blood red. Sp. gr. from 3.423 to 5.005. Before the blow pipe blackens, but does not melt. Tinges borax yellowish olive green. When digested in ammonia, it becomes black and often magnetic.

Variety 1. Red hæmatites.

Found in masses, and all the variety of forms of stalactites. Colour between brownish red and steel grey. Powder red. Internal lustre metallic. Texture fibrous. Hardness 9 to 10. Brittle. Sp. gr. 4.74†† to 5.005‡.

†† Gellert. ‡ Kirwan.

When pure it consists of red oxyd of iron, but it often contains manganese and alumina §.

§ Kirwan's Min. ii. 169.

Variety 2. Compact red iron ore.

Found massive and stalactitic; sometimes in crystals of various forms, but they seem to be only secondary; sometimes in columns like basalt.

Colour between brown red and steel grey. Stains the fingers. Lustre 1 to 0; often semimetallic. Texture compact. Hardness 7 to 9. Brittle. Sp. gr. 3.423 to 3.76† Sometimes invested with a rosy red ochre.

† Kirwan.

Variety 3. Red ochre.

Found sometimes in powder, sometimes indurated. Colour blood red. Stains the fingers. Lustre 0. Texture earthy. Hardness 3 to 5. Brittle.

Variety 4. Red scaly iron ore.

This variety is generally found incumbent upon other iron ores. Colour between cherry red and steel grey. Stains the fingers. Lustre silky, inclining to metallic. Texture foliated. Feels unctuous. Hardness 3 to 4. Brittle. Heavy.

225 Argillaceous iron ore.

SPECIES 6. Argillaceous iron ore ‡.

Oxyd of iron combined or mixed with [illegible].

This ore is exceedingly common; and though it contains less iron than the species already described, it is, in this country at least, preferred to them, because the method of extracting pure iron from it is easier, or rather because it is better understood.

‡ Kirw. ii. 173.

Colour most commonly dark brown. Streak red or yellowish brown. Sp. gr. from 2.673 to 3.471 †. Before the blow pipe blackens, and tinges borax olive green and blackish. It is composed of oxyd of iron, alumina, lime, silica in various proportions. It generally yields from 30 to 40 *per cent.* of iron.

† Kirwan.

Variety 1. Common argillaceous iron ore.

The minerals arranged under this variety differ considerably from each other in their external character. They are found in masses of various shapes, and often form large strata.

Colour various shades of grey, brown, yellow, and red. Streak reddish yellow or dark red. Lustre 0. Hardness from 3 to 8. Smells earthy when breathed upon.

Variety 2. Columnar or [illegible]form iron ore.

This variety is found in columns, adhering to each other, but easily separable: They are commonly incurvated, and their surface is rough. Colour brownish red. Streak dark red. Slightly stains the fingers. Lustre 0. Adheres strongly to the tongue. Sound hollow. Feel dry. Texture earthy.

Variety 3. Acinose iron ore.

This variety is found in masses, and is commonly lenticular. Colour generally brownish red. Lustre metallic, nearly. Texture granular. Hardness 5 to 6. Brittle.

Variety

Iron Ores.

Variety 4. Nodular, or kidney-form iron ore.
Ætites or *Eagle-stone*.

This variety, which was mentioned by the ancients, is generally found under the form of a rounded knob, more or less resembling a kidney, though sometimes it is quadrangular; and it contains within it a kernel, which is sometimes loose, and sometimes adheres to the outside rind. Colour of the stone yellowish brown; of the kernel ochre yellow. Surface generally fouled with earth. Lustre of the rind metallic; of the kernel 0. Hardness from 4 to 7. Brittle.

Variety 5. Pisiform or granular iron ore.

This variety occurs in rounded masses, from the size of a pea to that of a nut. Surface rough. Colour commonly dark brown. Streak yellowish brown. Hardness 5 to 6. Brittle.

The oolitic ore found at Creusot, near mount Cenis, belongs to this variety. It is composed of

50 lime,
30 iron,
20 alumina.
———
100

226 Lowland iron ore. * Kirw. ii. 179.

SPECIES 7. Lowland iron ore *.

This species of ore is supposed to consist of oxyd of iron, mixed with clay and phosphuret or phosphat of iron. It is called lowland ore, because it is found only in low grounds; whereas the last species is more commonly in high grounds; and is therefore called *highland ore*.

This ore occurs in amorphous masses, and also in grains or powder. Its colour is brown. Streak yellowish brown. Lustre 0, or common. Texture earthy. Hardness 3 to 5.

Variety 1. Meadow lowland ore.

Colour blackish or yellowish brown: Both colours often meet in the same specimen. Found in lumps of various sizes, often perforated. Fracture compact. Moderately heavy.

Frequently yields from 32 to 38 *per cent.* of iron.

Variety 2. Swampy iron ore.

This variety is generally found under water. It is in lumps, which are commonly perforated or corroded, and mixed with sand. Colour dark yellowish brown, or dark nut brown. Hardness 3 to 4. Brittle. Sp. gr. 2.944. It often contains .36 of iron.

Variety 3. Morassy iron ore.

This variety is found either in a loose form or in perforated lumps. Colour light yellowish brown. Stains the fingers. Hardness 3. Friable.

227 G. VI. Salts. Sparry iron ore.

GENUS VI. SALTS OF IRON.

SPECIES 1. Sparry iron ore (G).

This ore is common in Germany, France, and Spain. It is found sometimes in amorphous masses, and sometimes crystallized.

Its colour is white; but it becomes tarnished by exposure to the air, and then assumes various colours. Streak grey or white. External lustre often metallic; internal common or glassy. Transparency 1 or 2; sometimes 0. Texture foliated. Fragments rhomboidal. Hardness 5 to 7. Brittle. Sp. gr. 3.6 to 3.81. Not magnetic. Soluble in acids with very little effervescence. Before the blow-pipe decrepitates, becomes brownish black, and magnetic; but is scarcely fusible. Tinges borax smutty yellow, with some effervescence.

This ore, as Bergman ascertained, consists of iron, manganese, lime, and carbonic acid.

One specimen, according to his analysis, contained

38 iron,
24 manganese,
38 carbonat of lime.
———
100

Another contained 22 iron,
28 manganese,
50 carbonat of lime.
———
100

Whether the iron be combined with the carbonic acid is still a disputed point. The crystals of this ore are rhomboidal parallelopipeds; which is precisely the form of carbonat of lime. This amounts nearly to a demonstration, that the carbonic acid is combined with the lime; and that, as Cronstedt and Hauy have supposed, this ore is merely carbonat of lime, contaminated with a quantity of the oxyds of iron and manganese.

228 Arseniat of iron.

SPECIES 2. Arseniat of iron.

Mr Proust has discovered this ore in Spain. Its colour is greenish white. Its texture granular. Insoluble in water and nitric acid. When melted on charcoal, the arsenical acid escapes with effervescence ‡.

‡ Ann. de Chim. i. 195.

229 Sulphat of iron.

SPECIES 3. Sulphat of iron.

For a description of this salt, see CHEMISTRY, n° 631. in this *Suppl.*

ORDER VII. TIN ORES (H).

TIN is employed to cover plates of iron and copper, and to silver the backs of looking glasses: It enters into the composition of pewter; and forms a very important article in dyeing.

230 Mines.

Tin ores are by no means so common as the ores of the metals which we have already described. They are found only in the *primitive mountains* (I). Hence Werner supposes them to be the most ancient of all metallic ores. They occur most frequently in granite, sometimes in porphyry, but never in limestone.

Almost

(G) *Kirw.* II. 19[illegible].—*Bergman*, II. 184.—*Bayen. Jour. de Phys.* VII. 213.—*Razoumowski, Mem. Lausanne*, 1783, p. 149.

(H) *Geoffroy, Mem. Par.* 1738, p. [illegible].—*Morveau, Ann. de Chim.* XXIV. 127.

(I) Geologists have divided mountains into three classes; *primitive*, *secondary*, and *tertiary*. The *primitive* occupy the centre of all extensive chains; they are the highest, the most rugged, and exhibit the most pointed tops. They are considered as the most ancient mountains of the globe.

The *secondary* mountains occupy the outside of extensive ranges. They are usually composed of strata, more or less inclined, and commonly rest against the sides of the primitive mountains.—The *tertiary* mountains are much smaller than the others, and are often solitary. We use the terms *primitive*, *secondary*, &c. merely as

proper

Tin Ores.

Almost the only tin mines known to Europeans are those of Cornwal, Devonshire, Saxony, Bohemia, Silesia, Hungary, Gallicia; those of the island of Banca and the peninsula of Malacca in India; and those of Chili and Mexico in America.

231 G. I. Sulphurets. Sulphuret of tin and copper.

GENUS I. SULPHURETS OF TIN.

SPECIES 1. Sulphuret of tin and copper *.

Tin pyrites.

Hitherto this ore has only been found in Cornwal. There is a vein of it in that county, in the parish of St Agnes, nine feet wide, and twenty yards beneath the surface †.

Its colour is yellowish grey, passing into the steel grey. Not unlike grey copper ore. Lustre metallic. Hardness 5 to 6. Very brittle. Sp gr. 4.35 ‡. Before the blow-pipe it melts easily, with a sulphureous smell, into a black bead, and deposits a bluish oxyd on the charcoal.

The composition of this ore, as Klaproth informs us, was first discovered by Mr Raspe. According to Klaproth's analysis, it is composed of

34 tin,
36 copper,
25 sulphur,
3 iron,
2 earth.

100 §

* Kirw. ii. 200.
† Klaproth's Cornwall, p. 21.
‡ Klaproth.
§ Id. 58.

232 G. II. Oxyds. Brown oxyd of tin.

GENUS II. OXYDS OF TIN.

SPECIES 1. Brown oxyd of tin *.

Tinstone—Woodtin.

This ore, which may be considered as almost the only ore of tin, occurs in masses, in rounded pieces, and crystallized. These crystals are very irregular. Hauy supposes, that their primitive form is a cube †; but Romé de Lisle, with more probability, makes it an octohedron ‡; and in this opinion Mr Day agrees with him ‖. The octohedron is composed of two four-sided pyramids, applied base to base. The sides of the pyramids are isosceles triangles, the angle at the vertex of which is 70°, and each of the other angles 55°. The sides of the two pyramids are inclined to each other at an angle of 90° §. This primitive form, however, never occurs, but crystals of tinstone are sometimes found, in which the two pyramids are separated by a prism. For a complete description of the varieties of the crystals of tinstone, we refer the reader to *Romé de Lisle* and *Mr Day* *.

Its colour is commonly brown. Streak grey. Hardness 9 to 10. Sp. gr. 6.9 to 7.0. Brittle.

Variety 1. Common tinstone.

Colour dark brown; sometimes yellowish grey, and sometimes nearly white. Streak light grey. Somewhat transparent when crystallized. Hardness 10. Sp. gr. 6.9 to 6.97. Before the blow pipe it decrepitates, and on charcoal is partly reduced. Tinges borax white.

According to Klaproth, it is composed of

77.50 tin,
21.50 oxygen,
.25 iron,
.75 silica.

100.00 †

Variety 2. Woodtin.

This variety has hitherto been found only in Cornwal. It occurs always in fragments, which are generally rounded. Colour brown; sometimes inclining to yellow. Streak yellowish grey. Opaque. Texture fibrous. Hardness 9. Sp. gr. 7.0. Before the blow pipe becomes brownish red; decrepitates when red hot, but is not reduced.

Klaproth obtained from it .63 of tin; and, in all probability, it is an oxyd of tin nearly pure.

Metallic Ores.

ORDER VIII. ORES OF LEAD.

THE useful purposes to which lead in its metallic state is applied, are too well known to require description. Its oxyds are employed in painting, in dyeing, and sometimes also in medicine.

Ores of lead occur in great abundance in almost every part of the world. They are generally in veins; sometimes in siliceous rocks, sometimes in calcareous rocks.

233 G. I. Sulphurets. Galena, or pure sulphuret of lead.

GENUS I. SULPHURETS OF LEAD.

SPECIES 1. Galena, or pure sulphuret of lead ‡.

This ore, which is very common, is found both in masses and crystallized. The primitive form of its crystals is a cube. The most common varieties are the cube, sometimes with its angles wanting, and the octohedron, composed of two four-sided pyramids applied base to base: The summits of these pyramids are sometimes cuneiform, and sometimes their solid angles are wanting ‖.

Its colour is commonly bluish grey, like lead. Streak bluish grey and metallic. Lustre metallic. Sometimes stains

‡ Kirw. ii. 210.
‖ Romé de Lisle, iii. 364.

---

proper names, without affirming or denying the truth or falsehood of the theory on which these names are founded. That the reader may have a more accurate idea of the composition of these different classes of mountains, we have subjoined a list of the substances which, according to Werner, enter into the composition of each.

I. PRIMARY MOUNTAINS.

1. Granite,
2. Gneiss,
3. Micaceous shistus
4. Argillaceous shistus,
5. Syenite,
6. Porphyry,
7. Shistose porphyry,
8. Quartz,
9. Primitive limestone,
10. Serpentine,
11. Topaz rock.

II. SECONDARY MOUNTAINS.

1. Argillaceous shistus,
2. Rubble stone,
3. Secondary limestone,
4. Shistose hornblende,
5. Grunstein,
6. Amygdaloid.

III. TERTIARY MOUNTAINS.

Trap,
Argillaceous shistus,
Stratified limestone,
4. Sandstone,
5. Breccia,
6. Coal,
7. Chalk,
8. Sulphat of lime,
9. Rock salt,
10. Ferruginous clay,
11. Potters earth.

Ores of Lead.

stains the fingers. Texture foliated. Fragments cubical. Hardnefs 5 to 7; fometimes even 9. Brittle. Sp. gr. 6.884 to 7.786 §. Effervefces with nitric and muriatic acids. Before the blow-pipe decrepitates, and melts with a fulphureous fmell; part finks into the charcoal.

§ Watfon.

It is compofed of from .45 to .83 lead, and from .086 to .16 of fulphur. It generally contains fome filver, and fometimes alfo antimony aud zinc.

Variety 1. Common galena.

This variety correfponds nearly with the above defcription. Sp. gr. 7.051 to 7.786. Sometimes ftains the fingers.

Compact galena.

Found only in amorpheus maffes. Texture compact, inclining to foliated. Hardnefs 6 to 8. Sp. gr. 6.886 to 7.444. Luftre common. Streak lead grey, brighter and metallic. Often feels greafy, and ftains the fingers.

234 Sulphuret of lead, with filver and antimony

SPECIES 2. Sulphuret of lead, with filver and antimony*.

Plumbiferous antimoniated filver ore.

Found in amorphous maffes. Colour grey. Hardnefs 5 to 6. Brittle. Sp. gr. from 5.2 to 8.

* *Kirw.* ii. 119

Variety 1. Light grey filver ore.

Colour light bluifh grey. Streak light bluifh grey, and brighter Luftre metallic. Texture compact. Before the blow pipe partly evaporates, and leaves a filver bead on the charcoal, furrounded by yellow duft.

According to Klaproth, it contains

48.06 lead,
20.40 filver,
7.88 antimony,
12.35 fulphur,
2.25 iron,
7.00 alumina,
.25 filica.

98.09 †

† *Beiträge*, i. 172.

Variety 2. Dark grey filver ore.

Colour iron grey, verging on black. Powder black, and ftains the fingers. Luftre 0. Texture earthy.

According to Klaproth, it contains

41.00 lead,
21.50 antimony,
29.25 filver,
22.00 fulphur,
1.75 iron,
1.00 alumina,
.75 filica.

97.25 ‡

* *Ibid.* 175.

235 Blue lead ore.

SPECIES 3. Blue lead ore *.

* *Kirw.* ii. 220.

This ore, which is found in Siberia, Germany, and Hungary, and is very rare, occurs fometimes in maffes, and fometimes cryftallized in fix-fided prifms.

Colour between indigo blue aud lead grey; fometimes inclining to black. Internal luftre metallic. Streak brighter. Texture compact. Hardnefs 6. Sp. gr. 5.461 †. Before the blow pipe melts with a low blue flame and a fulphureous fmell, and is eafily reduced.

† *Gellert.*

236 Black lead ore.

SPECIES 4. Black lead ore ‡.

‡ *Kirw.* ii. 221.

This ore, which is found in Germany and Brittanny, and which is fuppofed to be common galena decayed, is fometimes in ftalactites of various forms, and fometimes cryftallized in fix fided prifms, which are generally truncated and confufed.

Metallic Ores

Colour black, often with fome ftreaks of red. Streak light bluifh grey. Internal luftre metallic. Hardnefs 5 to 6. Brittle. Sp. gr. from 5.744 ‖ to 5.77 *. Before the blow-pipe decrepitates, melts eafily, and is reduced.

‖ *Briffon.*
* *Gellert.*

According to the experiments of Laumont, this ore is a fulphuret of lead (or rather fulphuret of oxyd of lead), mixed with fome phofphat of lead.

237 Sulphuret of lead, bifmuth, and filver.

SPECIES 5. Sulphuret of lead, bifmuth, and filver.

This ore, which occurs in the valley of Schapbach in Saxony, was firft taken notice of by Selb, and afterwards defcribed by Weidenmann and Emerling.

Its colour is light bluifh grey. Its luftre metallic. Its fracture uneven. Hardnefs 5. Melts eafily before the blow pipe, emitting fome fmoke, and leaves a filver bead.

A fpecimen, analyfed by Mr Klaproth, contained

33.0 lead,
27.0 bifmuth,
15.0 filver,
16.3 fulphur,
4.3 iron,
0.9 copper.

96.5 †

† *Beiträge*, ii. 297.

238 G. II. Oxyds. Lead ochre.

GENUS II. OXYDS OF LEAD.

SPECIES 1. Lead ochre ‡.

This ore, which is a mixture of the oxyd of lead with various earths, is found maffive, and of various degrees of hardnefs.

‡ *Kirw.* ii. 205.

Its colour is either yellow, grey, or red. Luftre 0. Tranfparency 0 to 1. Hardnefs 6 to 8; fometimes in powder. Sp. gr. from 4.165 to 5.545 §. Texture compact. Effervefces with nitric and muriatic acids. Eafily reduced by the blow-pipe, leaving a black flag, unlefs the lead be mixed with too great a proportion of earth.

§ *Kirwan.*

239 G. III. Salts. Carbonat of lead.

GENUS III. SALTS OF LEAD.

SPECIES 1. Carbonat of lead †.

White lead fpar.

This ore of lead, which is very common, is fometimes in maffes, and fometimes cryftallized. But the cryftallization is in general fo confufed, that the primitive form of the cryftals has not yet been afcertained (κ).

† *Kirw.* ii 203.

Its colour is white. External luftre, waxy or filky, from 3 to 1; internal 1 to 2. Generally fomewhat tranfparent. Hardnefs 5 to 6. Brittle. Sp. gr. from 5.349 ‖ to 6.92 §. Effervefces with nitric and muriatic acids when they are heated. Soluble in fat oils. Blackened by fulphuret of ammonia *. Decrepitates when heated. Before the blow-pipe, in a filver fpoon, it becomes red by the yellow cone of the flame, while the blue cone renders it yellow †. On charcoal it is immediately reduced.

‖ *Kir.*
§ *Gellert.*
* *Pelletier, Ann. de Chim.* ix. 56.
† *Ribbentropp, Ann. de Chim.* xxv. 189.

It contains from .60 to .85 of lead, and from .18 to .24 of carbonic acid. It is generally contaminated with carbonat of lime and oxyd of iron.

SPECIES

(κ) See *Hauy, Jour. de Min.* Nº XXXI. 502. and *Romé de Lifle*, III. 380.

Ores of Lead.

241 Phosphat of lead † Kirw. ii 207.

SPECIES 2. Phosphat of lead †.

This ore, which is found in Siberia, Scotland, England, Germany, Carinthia, Brittany, &c. is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals, according to Romé de Lisle, is a dodecahedron, consisting of a six-sided rectangular prism, terminated by six sided pyramids, the sides of which are isosceles triangles (L). Sometimes the pyramids are truncated, and even altogether wanting. The crystals of this ore are often acicular.

Its colour is commonly green; sometimes yellowish or brownish, or greyish white. Streak commonly greenish white. Powder yellowish. External lustre, waxy, 2 to 3. Somewhat transparent, except when its colour is greyish white. Hardness 5 to 6. Brittle. Sp. gr. from 5.86 * to 6.27 †. Insoluble in water and sulphuric acid, and nearly insoluble in nitric acid; soluble in hot muriatic acid, with a slight effervescence ‡. Before the blow-pipe it easily melts on charcoal, and crystallizes on cooling: with soda the lead is in some measure reduced.

* Brisson. † Klaproth ‡ Fourcroy, Ann. de Chim. ii. 207.

The composition of this ore was first discovered by Gahn.

According to Fourcroy's analysis, a specimen from Erlenbach in Alsace, consists of

96	phosphat of lead,
2	phosphat of iron,
2	water.
100	

Or it contains

79	oxyd of lead,
1	oxyd of iron,
18	phosphoric acid,
2	water.
100 ¶	

¶ Ibid.

242 Arseniat of lead. § Kirw. ii. 209.

SPECIES 3. Arseniat of lead §.

This ore, which has hitherto been found only in Andalusia in Spain, and always in quartz or feldspar, is in small masses. Colour meadow green, often passing into wax yellow. Lustre waxy, 2. Transparency 2. Before the blow-pipe it melts, and retains its colour, and does not crystallize on cooling. When heated to whiteness, the arsenic acid escapes, and the lead is reduced *.

* Proust, Jour de Phys. xxx. 394.

242 Phosphat and arseniat of lead. † Kirw. ii. 210.

SPECIES 4. Phosphat and arseniat of lead.

Arsenio phosphat of lead †.

This ore, which has been found in Auvergne in France, is either in masses, or crystallized in small six-sided prisms, with curvilineal faces.

Colour yellowish green, or shews alternate layers of pale and light green. Powder yellowish. The crystals are somewhat transparent; but when massive, this ore is opaque. Hardness 5 to 7. Brittle. Sp. gr. 6.8465‡. Soluble in hot muriatic acid, but not in nitric. When heated it decrepitates. Before the blow-pipe melts easily, effervesces, emits a white smoke, with an arsenical smell. Some particles of lead are reduced, a brown fluid remains, which crystallizes on cooling like phosphat of lead.

‡ Brisson.

Metallic Ores.

According to Fourcroy, from whom the whole of this description has been taken, it is composed of

65	arseniat of lead,
27	phosphat of lead,
5	phosphat of iron,
3	water.
100 *	

* Ann. de Chim. ii. 23.

243 Molybdat of lead.

SPECIES 5. Molybdat of lead (M).

This ore, which is found in Carinthia and at Leadhills in Scotland, was first mentioned in 1781 by Mr Jacquin (N). It occurs either in masses, or crystallized in cubic, or rhomboidal, or octohedral plates.

Its colour is yellow. Streak white. Lustre waxy. Generally somewhat transparent. Texture foliated. Fracture conchoidal. Hardness 5 to 6. Sp. gr. 5.486 †; when purified from its gangue by nitric acid, 5.706 ‡. Soluble in fixed alkalies and in nitric acid. Communicates a blue colour to hot sulphuric acid. Soluble in muriatic acid, and decomposed by it. Before the blow-pipe decrepitates, melts into a yellowish grey mass, and globules of lead are reduced ||.

† Macquart ‡ Hatchett. || Macquart.

Klaproth first proved that this ore was molybdat of lead.

A very pure specimen, analysed by him, contained

64.42	oxyd of lead,
34.25	molybdic acid.
98.67 ¶	

¶ Beitrage, ii. 275.

According to the analysis of Mr Hatchett, it is composed of

58.40	oxyd of lead,
38.00	molybdic acid,
2.10	oxyd of iron,
.28	silica.
98.78 *	

* Phil. Trans. lxxxvi. 32.

Macquart found a specimen to contain

58.74	lead,
4.76	oxygen,
28.00	molybdic acid,
4.50	carbonat of lime,
4.00	silica.
100.00 †	

† Jour de Min N° xvii. 32.

Its gangue is carbonat of lime.

244 Sulphat of lead.

SPECIES 6. Sulphat of lead ‡.

This ore, which is found in Anglesey and in Andalusia, is generally crystallized. The crystals are regular octohedrons §, and very minute.

Colour white. Lustre 4. Transparency 4. Before the blow-pipe it is immediately reduced.

The composition of this ore was first ascertained by Dr Withering.

‡ Kirw. Min ii. 211. § Hauy, Jour. de Min N° xxxi 508.

Order IX. ORES OF ZINC.

Hitherto zinc has not been applied to a great variety of uses. It enters into the composition of brass; it is used in medicine; and Morveau has shewn that its oxyd

(L) *Cryst.* III. 391. See also *Hauy's* remarks on the same subject in the *Jour. de Min.* N° XXXI. 506.
(M) *Kirw.* II. 212.—*Klaproth, Ann. de Chim.* VIII. 103.—*Hatchett, Phil. Trans.* 1796, p. 285.
(N) In his *Miscellanea Austriaca*, Vol. II. p. 139.

Ores of Zinc.

oxyd might be employed with advantage as a white paint.

Ores of zinc are very abundant; they generally accompany lead ores, particularly galena. Calamine, or oxyd of zinc, has never been discovered in the primitive mountains.

245 G. I. Sulphurets Common sulphuret of zinc.

GENUS I. SULPHURETS OF ZINC.

SPECIES 1. Common sulphuret of zinc*.

Blende.

This ore very commonly accompanies sulphuret of lead. It occurs both in amorphous masses and crystallized. The primitive form of its crystals is a rhomboidal dodecahedron, consisting of a six sided prism, terminated by three-sided pyramids. All the faces of the crystals are equal rhombs. This dodecahedron may be mechanically divided into four equal rhomboidal parallelopipeds, and each of these into six tetrahedrons, whose faces are equal isosceles triangles. The figure of its integrant particles is the tetrahedron, similar to these*.

The principal varieties of its crystals are the tetrahedron; the octohedron; the octohedron with its edges wanting*; a 24 sided crystal, 12 of whose faces are trapezoids, and 12 elongated triangles†; and, lastly, a 28-sided figure, which is the last variety, augmented by four equilateral triangles†.

Colour yellow, brown, or black. Streak reddish, brownish, or grey. Lustre commonly metallic. Generally somewhat transparent. Texture foliated. Hardness 6 to 8. Sp. gr 3.92‡ to 4.1665¶. Before the blow-pipe decrepitates, and gives out white flowers of zinc, but does not melt. Borax does not affect it. When breathed upon, loses its lustre, and recovers it very slowly||.

† Fig 41.

† See Hauy, ibid and Romé de Lisle, iii 6.

‡ Gellert.

¶ Brisson.

|| Hauy, Jour de Min. ibid.

Variety 1. Yellow blende.

Colour commonly sulphur yellow, often passing into olive green or brownish red. Powder pale yellow. Streak yellowish or reddish grey, not metallic. Lustre metallic. Transparency 2 to 4. Often phosphoresces when scraped or rubbed*.

According to Bergman, it is composed of

64	zinc,
20	sulphur,
5	iron,
4	fluor acid,
1	silica,
6	water.
100†	

* Bergman, ii. 345.

† Ibid. 347.

Variety 2. Brown blende.

Colour different shades of brown. Surface often tarnished. Powder brownish grey. Streak reddish or yellowish grey, not metallic. Lustre commonly metallic. Transparency 0 to 2.

A specimen of this variety, analysed by Bergman, contained

44	zinc,
17	sulphur,
24	silica,
5	iron,
5	alumina,
5	water.
100‡	

‡ Ibid. 333.

Variety 3. Black blende.

Colour black, or brownish black; surface often tarnished blue; tips of the crystals often blood red. Powder brownish black. Streak reddish, brownish, or grey. Lustre common or metallic. Transparency 0 to 1; the red parts 2. Hardness 8.

A specimen of this variety, analysed by Bergman, contained

52	zinc,
26	sulphur,
4	copper,
8	iron,
6	silica,
4	water.
100‡	

Metallic Ores.

‡ Bergman, ii. 335.

246 G. II. Oxyds. White oxyd of zinc.

GENUS II. OXYDS OF ZINC.

SPECIES 1. White oxyd of zinc†.

Calamine.

This ore is either found loose, or in masses, or crystallized. The primitive form of its crystals appears, from the mechanical division of one of them by Mr Hauy, to be an octohedron composed of two four-sided pyramids, whose sides are equilateral triangles†. But the crystals are minute, and their figure not very distinct They are either four or six sided tables with bevelled edges, six-sided prisms, or three-sided pyramids.

Colour commonly white, grey, or yellow. Lustre often 0, sometimes 2 or 1. Opaque. The crystals are somewhat transparent. Hardness from 4 to 9, sometimes in powder. Sp. gr. from 2.585 to 3.674‡. When heated, becomes electric, without friction, like the tourmaline†. Not blackened by sulphuret of ammonia. Soluble in sulphuric acid. Before the blow-pipe decrepitates, and does not melt.

† Kirw. ii. 233.—Berg. ii. 321.

† Jour. de Min. No. xxxii. 596.

‡ Kirwan.

† Hauy, Jour. de Min. ibid.

This ore consists of oxyd of zinc more or less contaminated with iron, silica, lime, and other foreign ingredients. In one specimen Bergman found the following ingredients:

84	oxyd of zinc,
3	oxyd of iron,
12	silica,
1	alumina.
100 ¶	

¶ Bergman, ii. 323.

In another specimen, which gelatinized with acids, like zeolite, Klaproth found 66 oxyd of zinc,

33	silica.
99	

In another specimen, analysed by Pelletier, the contents were

52	silica,
36	oxyd of zinc.
12	water.
100 *	

* Jour. de Phys. xx. 428.

Mr Kirwan has divided this species into three varieties.

Variety 1. Friable calamine.

In masses which easily crumble between the fingers. Lustre 0. Opaque. Texture earthy. When its colour is white, it is pure oxyd of zinc; when yellow, it is mixed with oxyd of iron. The white often becomes yellow when placed in a red heat, but resumes its colour on cooling. Common in China, where it is called *wohan* or *ore of Tutenago.*

Ores of Antimony

Variety 2. Compact calamine.

Colour different shades of grey; sometimes yellow or brownish red. Lustre 0. Opaque. Texture compact.

Variety 3. Striated calamine.

This variety alone is found crystallized; but, like the others, it is also often amorphous. Colour white, and also various shades of grey, yellow, and red. Somewhat transparent. Texture striated. Lustre 2 to 1.

247 G. III. Salts. Sulphat of zinc.

GENUS III. SALTS OF ZINC.

SPECIES 1. Sulphat of zinc.

For a description of this salt, we refer to CHEMISTRY, n° 643. *Suppl.*

ORDER X. ORES OF ANTIMONY.

ANTIMONY is much used to give hardness to those metals which otherwise would be too soft for certain purposes: printers types, for instance, are composed of lead and antimony. It is used also in medicine.

Ores of antimony are found abundantly in Germany, Hungary, France, Spain, Britain, Sweden, Norway, &c. They often accompany galena and hæmatites. They are found both in the secondary and primitive stratified mountains. Their gangue (o) is often quartz and sulphat of barytes.

248 G. I. Alloys Native antimony. * Kirw. ii. 245.

GENUS I. ALLOYS OF ANTIMONY.

SPECIES 1. Native antimony *.

This mineral, which was first discovered by Dr Swab, has been found in Sweden and in France, both in masses and kidney-shaped lumps. Colour white, between that of tin and silver. Lustre metallic. Texture foliated. Hardness 6. Sp. gr. above 6. Deflagrates with nitre. Before the blow-pipe melts and evaporates, depositing a white oxyd of antimony.

It consists of antimony, alloyed with 3 or 4 *per cent.* of arsenic.

249 G. II. Sulphurets. Grey ore of antimony. * Kirw. ii. 247.

GENUS II. SULPHURETS OF ANTIMONY.

SPECIES 1. Grey ore of antimony *.

This ore, which is the most common, and indeed almost the only ore of antimony, occurs both massive, disseminated, and crystallized. Its crystals are four-sided prisms, somewhat flattened, whose sides are nearly rectangles, terminated by short four-sided pyramids, whose sides are trapeziums †. Sometimes two of the edges are wanting, which renders the prism six-sided ‡.

Colour grey. Lustre metallic. Streak grey, metallic, and brighter. Powder black or greyish black. Hardness 6 to 7. Sp. gr. from 4.1327 to 4.516 ¶. Often stains the fingers. Before the blow pipe melts easily, burns with a blue flame, and deposits a white oxyd on the charcoal. When placed in an open vessel, over a slow fire, the sulphur evaporates, and leaves a grey oxyd of antimony. This oxyd, if fused with tartar, is reduced.

† *Romé de Lisle*, iii. 49

‡ *Ibid.*—See also Hauy, *Jour. de Min.* N° xxii. 706.

¶ *Brisson.*

This ore, when taken out of the mine, almost always contains a large proportion of quartz or other stony matter. When pure, it is composed of about

Metallic Ores.

74 antimony,
26 sulphur.
———
100

Werner has divided this species into three varieties.

Variety 1. Compact sulphuret.

Colour bluish grey, surface often tarnished, and then it is blue or purplish. Lustre 1 to 2. Texture compact. Fracture fine grained, uneven. Powder black, dull, and earthy. Slightly stains the fingers.

Variety 2. Foliated sulphuret.

Colour light steel grey. Lustre 3 to 4. Texture foliated. Powder as that of the last variety.

Variety 3. Striated sulphuret.

Colour dark steel grey, and light bluish grey; surface often tarnished, and then it is dark blue or purplish. Lustre 3 to 2. Texture striated Powder greyish black. This variety alone has been hitherto found crystallized.

250 Plumose antimonial ore. † Kirw. ii. 251.

SPECIES 2. Plumose antimonial ore †.

Sulphurets of antimony and arsenic.

This species, which is sometimes found mixed with the crystals of sulphurated antimony, is in the form of brittle, capillary, or lanuginous crystals, often so small that they cannot be distinctly seen without a microscope.

Colour steel or bluish grey, often tarnished, and then brown or greyish black. Lustre 1, semimetallic. Before the blow-pipe emits a smoke, which deposits a whitish and yellowish powder on the charcoal: it then melts into a black slag.

It is supposed to consist of sulphur, antimony, arsenic, and some silver.

251 Red antimonial ore. † Kirw. ii 250.

SPECIES 3. Red antimonial ore †.

Hydrosulphuret of antimony.

This species is generally found in cavities of sulphurated antimonial ore. It is crystallized in delicate needles, often diverging from a common centre.

Colour red. Lustre 2, silky. Sp. gr. 4.7. Before the blow-pipe melts easily, and evaporates with a sulphureous smell.

This ore has not been analysed. Mineralogists have supposed it to be a natural kermes. If so, we may conclude, from the experiments of Berthollet *, that it is a hydrosulphuret of antimony, and consequently composed of oxyd of antimony, sulphur, and sulphurated hydrogen gas.

* *Ann. de Chim.* xxv. 259.

252 G. III. Oxyds of antimony

GENUS III. OXYDS OF ANTIMONY.

There is a substance found incumbent on sulphuret of antimony, of a yellow colour, and an earthy appearance, which has been supposed an oxyd of antimony, and denominated antimonial ochre. But hitherto it has not been analysed.

GENUS

(o) The word *gang* is used by German mineralogists to denote a metallic vein. Now, it is not often that these veins consist entirely of *ore;* in general, they contain stony matter besides. For instance, in the copper mine at Airthry, near Stirling, the copper ore is merely a narrow stripe in the middle of the vein, and the rest of it is filled up with sulphat of barytes. We use the word *gangue* (as the French do), to denote, not the *metallic* vein, but the *stony* matter which accompanies the ore in the vein. The gangue of the copper ore at Airthry is sulphat of barytes.

Order I. Bismuth? (margin)

GENUS IV. SALTS OF ANTIMONY.

SPECIES 1. Muriat of antimony*.

This ore, which has been found in Bohemia, is sometimes in quadrangular tables; fometimes in acicular cryftals grouped like zeolites; and fometimes in prifms.

253 G. IV. Salts. Muriat of antimony. * Kirw. ii. 251.

Colour pale yellowifh or greyifh white. Luftre 2 to 1, nearly metallic. Tranfparency 2. Texture foliated. Melts eafily by the flame of a candle, and emits a white vapour.†. Before the blow pipe decrepitates; when powdered, and juft ready to melt, it evaporates, and leaves a white powder around. Between two pieces of coal it is reducible to a metallic ftate.

† Pavs, Jour. de Min. N° xxxi. 669.

ORDER XI. ORES OF BISMUTH*.

* Pott, Obs. Chym. 134.—Geoffroy, Mem. Par. 1753, p. 296.

Bismuth is employed in the manufacture of pewter, of printers types, in foldering; and perhaps alfo its property of rendering other metals more fufible, might make it ufeful in anatomical injections. The quantity confumed in commerce is not great.

It has been found only in the primitive mountains, and is by no means common. When unaccompanied by any other metal, it does not form veins, but kidney-form maffes. It often accompanies cobalt. Its gangue is commonly quartz. Its ores are not very abundant. They have been found chiefly in Sweden, Norway, Tranfylvania, Germany, France, and England

254 G. I. Alloys. Native bifmuth.

GENUS I. ALLOYS OF BISMUTH.

SPECIES 1. Native bifmuth*.

* Kirw. ii 264.

This mineral, which is found at Schneeberg, Johangeorgenftadt, &c. in Germany, has commonly the form of fmall plates lying above one another. Sometimes it is cryftallized in four-fided tables, or indiftinct cubes.

Colour white with a fhade of red; furface often tarnifhed red, yellow, or purple. Luftre metallic, 3 to 2. Opaque. Texture foliated or ftriated. Hardnefs 6. Sp. gr. 9.022† to 9.57‡. Exceedingly fufible. Before the blow-pipe gives a filvery white bead, and at laft evaporates in a yellowifh white fmoke, which is depofited on the charcoal.

† Briffon. ‡ Kirwan.

It is generally accompanied by cobalt, and fometimes contains arfenic.

255 G. II. Sulphurets. Common fulphuret of bifmuth.

GENUS II. SULPHURETS OF BISMUTH.

SPECIES 1. Common fulphuret of bifmuth*.

* Kirw. ii. 266.—Sage, Mem. Par. 1782, 307.

This ore, which is found in Sweden, Saxony, and Bohemia, occurs fometimes in amorphous maffes, and fometimes in needleform cryftals.

Colour commonly bluifh grey, fometimes white; furface often tarnifhed yellow, red, and purple. Powder black and fhining. Luftre metallic, 2 to 3. Streak obfcurely metallic. Texture foliated. Hardnefs 5. Brittle. Sp gr. 6.131† to 6.4672‡. When held to the flame of a candle, it melts with a blue flame and fulphureous fmell. Before the blow-pipe emits a reddifh yellow fmoke, which adheres to the charcoal. This powder becomes white when it cools, and refumes its former colour when the flame is directed upon it*.

† Kirwan.

* Gillet, Jour. de Min. N° xxii. 58.

This ore, according to Sage, contains 60 bifmuth, And, according to La Peroufe, it holds 36 fulphur.

A fpecimen, analyfed by Klaproth, contained

95 bifmuth,

5 fulphur.

100†

† Beiträge, i. 256.

It is commonly accompanied by quartz, afbeftos, or fpairy iron ore.

256 G. III. Oxyds. Yellow oxyd of bifmuth.

GENUS III. OXYDS OF BISMUTH.

SPECIES 1. Yellow oxyd of bifmuth‡.

Bifmuth ochre.

‡ Kirw. ii. 265.

This ore generally accompanies the two fpecies already defcribed. It is found in two ftates; either of an earthy confiftence, or cryftallized in cubes or quadrangular plates.

Colour ufually greenifh yellow, fometimes grey. Soluble in nitrous acid without effervefcence, and may in a great meafure be precipitated by the effufion of water.

ORDER XII. ORES OF ARSENIC.

Arsenic is ufed as an alloy for feveral other metals, efpecially copper. It is fometimes employed to facilitate the fufion of glafs, or to render it opaque, in order to form an enamel. Preparations of arfenic are employed as paints; and, like moft other violent poifons, it has been introduced into medicine.

This metal is fcattered in great abundance over the mineral kingdom, accompanying almoft every other metal, and forming alfo fometimes peculiar veins of its own. Of courfe it occurs in almoft every fpecies of mountain, and is accompanied by a variety of gangues.

257 G. I. Alloys. Native arfenic.

GENUS I. ALLOYS OF ARSENIC.

SPECIES 1. Native arfenic†.

† Kirw. ii. 255.

This mineral is found in different parts of Germany. It occurs generally in maffes of various fhapes, kidney-form, botryoidal, &c.

Colour that of fteel. Its furface quickly becomes tarnifhed by expofure to the air. Luftre metallic (when frefh), 3 to 2. Streak bluifh grey, metallic, and bright. Powder dull and black. Texture compact. Hardnefs 7 to 8. Brittle. Sp. gr. 5.67† to 5.7249‡. Gives an arfenical fmell when ftruck. Before the blow-pipe emits a white fmoke, diffufes a garlic fmell, burns with a blue flame, gradually evaporates, depofiting a white powder.

† Kirwan. ‡ Briffon.

It is always alloyed with fome iron §, and often contains filver, and fometimes gold.

§ De Born. Catal. of M. Raab, ii. 494.

258 G. II. Sulphurets. Orpiment.

GENUS II. SULPHURETS OF ARSENIC.

SPECIES 1. Orpiment (γ).

Auripigmentum.

This ore, which is found in Hungary, Wallachia, Georgia, and Turkey in Afia, is either maffive or cryftallized. The cryftals are confufed, and their figure cannot be eafily determined; fome of them appear octohedrons, and others minute four-fided prifms.

Its colour is yellow. Streak orange yellow. Luftre waxy, 2 to 3. Tranfparency from 0 to 2. Texture foliated. Hardnefs 4 to 8. Sp. gr. from 3.048* to 3.521‡. Effervefces with hot nitric acid. Burns with a

§ Brisson.

|| Hauy, Jour. de Min. No xxxii. 612.

260 G. III. Oxyds. White oxyd of arsenic. GENUS III. OXYDS OF ARSENIC.

SPECIES 1. White oxyd of arsenic*.

Native calx of arsenic.

This ore is found in various parts of Germany, Hungary, &c. either in powder, or massive, or crystallized in prismatic needles.

Colour white or grey, often with a tint of red, yellow, green, or black. Lustre common, 1 to 2. Transparency 1 to 0; when crystallized, 2. Texture earthy. Hardness 6. Brittle. Sp. gr. 3.7†. Soluble in hot diluted nitric acid without effervescence. Soluble at 60° Fahrenheit in 80 times its weight of water. Before the blow-pipe sublimes, but does not inflame. Tinges borax yellow.

* Kirw. ii. 258—Berg. ii. 285.

† Kirwan.

ORDER XIII. COBALT ORES.

COBALT is employed to tinge glass of a blue colour, and is useful in painting upon porcelain.

Cobalt ores are found almost exclusively in the stratified mountains, except one species, sulphuret of cobalt, which affects the primitive mountains. They are not very abundant; and for that reason cobalt is more valuable than many of the other metals which have been already treated of. They are commonly accompanied by nickel, bismuth, or iron. They are most abundant in Germany, Sweden, Norway, and Hungary; they have been found also in Britain and France, but not in any great quantity.

261 G. I. Alloys. Cobalt alloyed with arsenic. GENUS I. ALLOYS OF COBALT.

SPECIES 1. Cobalt alloyed with arsenic†.

Dull grey cobalt ore.

This ore, which occurs in different parts of Germany, is either amorphous or crystallized. The forms of its crystals are the cube; sometimes the cube with its angles, or edges, or both wanting; and the octohedron ‡.

† Kirw. ii.

‡ Romé de Lisle, iii. 3.

Its colour, when fresh broken, is whitish or bluish grey, sometimes with a shade of red; when exposed to the air it soon becomes tarnished. Streak bluish grey and metallic. Lustre scarcely metallic, 0 to 1. Texture compact. Hardness 10. Difficultly frangible. Sp. gr. when amorphous, 5.309 to 5.571§; when crystallized 7.7207†. When struck it gives out an arsenical smell. Before the blow-pipe it gives out an arsenical vapour, becomes magnetic, and melts easily, unless it contains a great quantity of iron. Tinges borax dark blue, and a small metallic bead is obtained.

§ Kirw. ii. 270.

† Hauy, Jour. de Min. No xxxii. 588.

A specimen of this ore from Cornwall, examined by Mr Klaproth, contained 20 cobalt,
24 iron,
33 arsenic,

77

with some bismuth and stony matter *.

* Klaproth's Cornwall, p 61.

Another specimen from Tunaberg, according to the analysis of the same chemist, contained
55.5 arsenic,
44.0 cobalt,
.5 sulphur.

100†

† Beitrage, ii. 307.

262 G. II. Sulphurets. White cobalt ore. GENUS II. SULPHURETS OF COBALT.

SPECIES 1. White cobalt ore ‡.

Sulphuret of cobalt, arsenic, and iron.

The descriptions which different mineralogists have given of this ore are so various, that it is impossible not to suppose that distinct substances have been confounded together.

It occurs either in masses, or crystallized in cubes, dodecahedrons, octohedrons, and icosahedrons.

Colour tin white, sometimes tarnished reddish or yellowish. Powder steel grey. Lustre partly metallic, and from 2 to 4; partly 0 or 1. Texture foliated. Hardness 8 to 9. Sp. gr. from 6.284† to 6.4509‡. Before the blow-pipe generally gives out an arsenical vapour, and does not melt.

‡ Kirw. ii. 273.—Sage, Jour de Phys. xxx. 53.

† Kirwan.

‡ Hauy.

The analyses that have been given of this ore are very various. Sometimes it has been found to contain no arsenic nor iron, and sometimes to contain both. A specimen from Tunaberg in Sweden, which ought to belong to this species, was analysed by Tassaert, and found to consist of 49 arsenic,
36.6 cobalt,
5.6 iron,
6.5 sulphur.

97.8†

† Ann. de Chim. xxvi.

Klaproth found a specimen of the same ore to contain 55.5 arsenic,
44.0 cobalt,
0.5 sulphur.

100.0‡

263 G. III. Oxyds. Black cobalt ore or ochre. GENUS III. OXYDS OF COBALT.

SPECIES 1. Black cobalt ore or ochre§.

This ore, which occurs in different parts of Germany, is either in the form of a powder, or indurated.

Colour black, often with a shade of blue, grey, brown, or green. Lustre 0 to 1. Streak brighter. Hardness (of the indurated) from 4 to 8. Sp. gr. 3 to 4. Soluble in muriatic acid. Tinges borax blue.

Ores of Nickel.

264 Brown cobalt ore. * Kirw. ii. 270.

SPECIES 2. Brown cobalt ore*.

Colour greyish or dark leather brown. Streak brighter, unctuous. Communicates a pale blue tinge in fusion.

205 Yellow cobalt ore. † Ibid.

SPECIES 3. Yellow cobalt ore †.

Colour yellow. Dull and earthy. Hardness 4 to 5. Texture earthy. Streak brighter, unctuous. Gives a weak blue tinge.

206 G. IV. Salts. Arseniat of cobalt. ‡ Id. 278.

GENUS IV. SALTS OF COBALT.

SPECIES 1. Arseniat of cobalt ‡.

Red cobalt ore.

This species, like most other ores of cobalt, has neither been accurately described nor analysed.

It is found in masses of various shapes, and crystallized in quadrangular tables or acicular prisms.

Colour red. Lustre from 2 to 3, sometimes 0. Transparency 0 to 2. Hardness 5 to 7. Brittle. Before the blow pipe becomes blackish grey. Diffuses a weak arsenical smell. Tinges borax blue.

ORDER XIV. ORES OF NICKEL.

HITHERTO nickel has been found in too small quantities to be applied to any use; of course there are, properly speaking, no mines of nickel. It occurs only (as far as is yet known) in the secondary mountains, and it commonly accompanies cobalt. It has been found in different parts of Germany, in Sweden, Siberia, Spain, France, and Britain.

267 G. I. Sulphurets. Sulphuret of nickel with arsenic and iron. * Ibid. 286.

GENUS I. SULPHURETS OF NICKEL.

SPECIES 1. Sulphuret of nickel with arsenic and iron.

*Kupfer nickel**.

This, which is the most common ore of nickel, occurs either massive or disseminated, but never crystallized.

Colour often that of copper, sometimes yellowish white or grey. Recent fracture often silver white. Lustre metallic, 2 to 3. Texture compact. Hardness 8. Sp. gr. 6.6086 to 6.6481 ‡. Soluble in nitric and nitro-muriatic acids. Solution green. Before the blow-pipe exhales an arsenical smoke, and melts into a bead which darkens by exposure to the air.

‡ Brisson.

It is composed of various proportions of nickel, arsenic, iron, cobalt, sulphur; often contains bismuth, and sometimes silver and copper.

268 G. II. Oxyds. Nickel ochre. * Kirw. ii. 284.

GENUS II. OXYDS OF NICKEL.

SPECIES 1. Nickel ochre*.

This mineral occurs either in the form of a powder, or indurated, and then is either amorphous, or crystallized in acicular form crystals. The powder is generally found on the surface of other nickel ores.

Colour different shades of green. Lustre 1 to 0. Texture earthy. Sp. gr. considerable. Slowly dissolves in acids: solution green. Before the blow-pipe does not melt; but gives a yellowish or reddish brown tinge to borax.

This ore often contains sulphat of nickel, which is soluble in water. The solution, when evaporated, gives oblong rhomboidal crystals, from which alkalies precipitate a greyish green oxyd. This oxyd is soluble by acids and by ammonia. The acid solution is green; the alkaline blue.

Metallic Ores.

269 G. III. Salts. Arseniat of nickel. † Kirw. ii. 285.

GENUS III. SALTS OF NICKEL.

SPECIES 1. Arseniat of nickel †.

This ore, which was lately discovered at Regendorff by Mr Gmelin, is found in shapeless masses, and is often mixed with plates of sulphat of barytes.

Colour pale grey, here and there mixed with pale green. Streak white. Lustre 0. Texture compact. Hardness 7. Difficultly frangible. Sp. gr. considerable. Adheres slightly to the tongue, and gives an earthy smell when breathed on. Soluble in hot nitric and muriatic acids: solution green.

Contains some cobalt and alumina.

ORDER XV. ORES OF MANGANESE (q).

HITHERTO manganese, in its metallic state, has scarcely been put to any use; but under the form of an oxyd it has become of great importance. The oxyd of manganese has the property of rendering colourless a variety of bodies which injure the transparency of glass; and it has been long used in glass manufactories for this purpose under the name of *glass soap*. By means of the same oxyd, oxy-muriatic acid is prepared, which has rendered manganese of great importance in bleaching. Not to mention the utility of manganese to the chemist, the property which it has of facilitating the oxydation of other metals, and of rendering iron more fusible—will probably make it, in no very remote period, of very considerable importance in numerous manufactories.

Ores of manganese occur often in strata, both in the primitive and secondary mountains; scarcely ever, however, we believe, in those mountains which are considered as the most ancient of all. They are very common, having been found abundantly in Germany, France, Spain, Britain, Sweden, Norway, Siberia, and other countries.

270 G. I. Oxyds.

GENUS I. OXYDS OF MANGANESE.

Hitherto manganese has only been found in the state of oxyd. La Perouse, indeed, suspected that he had found it in a metallic state: but probably there was some mistake or other in his observations.

271 Oxyd of manganese combined with barytes.

SPECIES 1. Oxyd of manganese combined with barytes.

This species, which exists in great abundance in Romaneche near the river Soane in France, is found massive, forming a stratum in some places more than 12 feet thick.

Colour greyish black or brownish black, of great intensity. Lustre, external, 0; internal, metallic, 1. Soon tarnishes by exposure to the air, and then becomes intensely black. Texture granular. Fracture uneven; sometimes conchoidal. Often porous. Hardness 11. Difficultly frangible. Sp gr. from 3.950 to 4.10. Absorbs water. When taken out of water after a minute's immersion, it has a strong argillaceous smell. Conducts electricity nearly as well as if it were in a metallic state ‡. Infusible by the blow-pipe. Tinges soda red; the colour disappears before the blue cone of flame, and is reproduced by the action of the yellow flame.

§ *Jour. de Phys.* xxxi. 22.

ORDER XVI. ORES OF TUNGSTEN.

As no easy method has hitherto been discovered of reducing tungsten to a metallic state, we need not be surprised that it has been applied to no use. Ores of tungsten are by no means common. They have hitherto been found only in the primitive mountains. Their gangue is commonly quartz. They very often accompany tin ores.

276 G. I. Oxyds. Wolfram.

GENUS I. OXYDS OF TUNGSTEN.

SPECIES 1. Wolfram (R).

Oxyds of tungsten, iron, and *manganese—Tungstat of iron* and *manganese*.

This species is found in different parts of Germany, in Sweden, Britain, France, and Spain; and is almost constantly accompanied by ores of tin. It occurs both massive and crystallized. The primitive form of its crystals, according to the observations of Mr Hauy, is a rectangular parallelopiped ‡, whose length is 8.66, whose breadth is 5, and thickness 4.33 *. It is not common, however, to find crystals of this perfect form; in many cases, the angles, and sometimes the edges, of the crystal are wanting ‡; owing, as Mr Hauy has shewn, to the superposition of plates, whose edges or angles decrease according to a certain law †.

‡ Fig. 42. * *Jour. de Min.* N° xix. 8. ‡ Fig. 43. † *Jour de Min.* N° xix. 8.

Colour brown or brownish black. Streak reddish brown. Powder stains paper with the same colour. Lustre external, 2; internal, 2 to 3; nearly metallic. Texture foliated. Easily separated into plates by percussion. Hardness 6 to 8. Sp. gr. from 7.006 * to 7.333 †. Moderately electric by communication. Not magnetic. Infusible by the blow-pipe. Forms with borax a greenish globule, and with microcosmic salt a transparent globule of a deep red ¶.

* *Kirwan*. † *Hauy*. ¶ *Vauquelin, Jour de Min*, N° xix. 11.

The specimen of this ore examined by Messrs d'Elhuyarts, was composed of

65	oxyd of tungsten,
22	oxyd of manganese,
13	oxyd of iron.

§ Vauquelin, Jour. de Min. N° xix 11.

Genus II. salts of tungsten.

species 1. Tungstat of lime (s).

Tungsten.

277 G. II Salts. Tungstat of lime. This ore, which is now exceedingly scarce, has hitherto been found only in Sweden and Germany. It is either massive or crystallized; and, according to Hauy, the primitive form of its crystals is the octohedron †.

† Jour de Min. N° xxxiii. 657.

Colour yellowish white or grey. Lustre 3 to 2. Transparency 2 to 3. Texture foliated. Hardness 6 to 9. Sp. gr, 5.8 to 60665. Becomes yellow when digested with nitric or muriatic acids. Infusible by the blow-pipe. With borax forms a colourless glass, unless the borax exceed, and then it is brown. With microcosmic salt it forms a blue glass, which loses its colour by the yellow flame, but recovers it in the blue flame ‡.

‡ Scheele and Bergman.

It is composed of about 70 oxyd of tungsten,
30 lime,

100

with a little silica and iron §.

§ Scheele.

species 2. Brown tungstat.

278 Brown tungstat. This ore is found in Cornwal, and is either massive or composed of small crystalline grains.

Colour grey, variegated with yellow and brown. Lustre 2, waxy. Hardness 6 to 7. Sp. gr. 5.57. Its powder becomes yellow when digested in aqua regia.

According to Klaproth, it is composed of

88 oxyd of tungsten,
11.5 lime.

99.5

Order XVII. ORES OF MOLYBDENUM.

If ever molybdenum be found in abundance, it will probably be useful in dyeing and painting. At present it is very scarce, having only been found in Sweden, Germany, Carniola, and among the Alpes. Like tin and tungsten, it affects the primitive mountains.

Genus I. sulphuret of molybdenum.

species 1. Common sulphuret (t).

Molybdena.

279 G. I. Sulphuret. Common sulphuret. This ore, which is the only species of molybdenum ore at present known, is found commonly massive; sometimes, however, it is crystallized in hexahedral tables.

Colour light lead grey; sometimes with a shade of red. Streak bluish grey, metallic. Powder bluish. Lustre metallic, 3 to 2. Texture foliated. Lamellæ slightly flexible. Hardness 4. Sp. gr. 4.569 * to 4.7385 †. Feels greasy; stains the fingers. Marks bluish black. A piece of resin rubbed with this mineral becomes positively electric ‡. Insoluble in sulphuric and muriatic acids; but in a boiling heat colours them green. Effervesces with warm nitric acid, leaving a grey oxyd undissolved. Before the blow-pipe, on a silver spoon, emits a white smoke, which condenses into a white powder, which becomes blue in the internal, and loses its colour in the external, flame. Scarcely affected by borax or microcosmic salt. Effervesces with soda, and gives it a reddish pearl colour.

* Kirwan. † Brisson. ‡ Hauy, Jour. de Min. N° xix. 70.

Composed of about 60 molybdenum,
40 sulphur.

100 *

* Klaproth.

Order XVIII. ORES OF URANIUM.

Uranium has hitherto been found only in Germany, and has not been applied to any use. The only two mines where it has occurred are in the primitive mountains.

Genus I. oxyds of uranium.

species 1. Sulphuret of uranium †.

Pechblende.

280 G I. Oxyds. Sulphuret of uranium. This ore, which has been found at Johanngeorgenstadt in Saxony, and Joachimsthal in Bohemia, is either massive or stratified with other minerals.

† Kirwan, ii. 305.

Colour black or brownish black; sometimes with a shade of grey or blue. Streak darker. Powder opaque and black. Lustre semimetallic, from 3 to 1. Fracture conchoidal. Hardness 7 to 8. Very brittle. Sp. gr. from 6.3785 ‡ to 7.5, and even higher §. Imperfectly soluble in sulphuric and muriatic acids; perfectly in nitric acid and aqua regia. Solution wine yellow. Infusible with alkalies in a crucible; infusible by the blow-pipe *per se*. With borax and soda forms a grey opaque slag; with microcosmic salt, a green glass.

‡ Morveau, Jour. de Min. N° xxxii 610. § Klaproth, Beiträge, ii. 197.

Composed of oxyd of uranium and sulphur, and mixed with iron and silica, and sometimes lead.

A specimen of this ore from Joachimsthal, analysed lately by Klaproth, contained

86.5 uranium,
6.0 sulphuret of lead,
5.0 silica,
2.5 oxyd of iron,

100.0 *

* Beiträge, ii. 221.

species 2. Yellow oxyd of uranium ‡.

Uranitic ochre.

281 Yellow oxyd of uranium. This ore is generally found on the surface of the last species at Johanngeorgenstadt, and is either massive or in powder.

‡ Kirwan, ii. 303.

Colour yellow, red, or brown. Streak of the yellow sorts yellow; of the red, orange yellow. Lustre 0. Slightly stains the fingers. Feels meagre. Texture earthy. Hardness 3 to 4. Sp. gr. 3.2438 ‖. Infusible by the blow-pipe; but in a strong heat becomes brownish grey.

‖ Hauy, Jour. de Min. ibid.

Composed of oxyd of uranium and oxyd of iron.

Genus

(s) *Kirw.* II. 314.—*Scheele's Works* (French translation), II. 81.—*Bergman, ibid.* p. 94.—*Crell, Chem. Annalen.* 1784. 2 *Band* 195.

Ores of Titanium.

282
G. II. Salts Carbonat of uranium

GENUS II. SALTS OF URANIUM.

SPECIES 1. Carbonat of uranium ¶.

This substance is also found at Johanngeorgenstadt, and near Eibenstock and Rheinbreidenbach §. It is sometimes amorphous, but more commonly crystallized. Its crystals are square plates, octohedrons, and six sided prisms.

¶ *Kirwan*, ii. 304.
§ *Gmelin*.

Colour green; sometimes nearly white; sometimes, though rarely, yellow. Streak greenish white. Lustre 3 to 2; internal, 2; sometimes pearly; sometimes nearly metallic. Transparency 2 to 3. Texture foliated. Hardness 5 to 6. Brittle. Soluble in nitric acid without effervescence. Infusible by alkalies.

Composed of carbonat of uranium, with some oxyd of copper. When its colour is yellow it contains no copper.

ORDER XIX. ORES OF TITANIUM.

TITANIUM has been known for so short a time, and its properties are yet so imperfectly ascertained, that many of its uses must remain to be discovered. Its oxyd, as we learn from Mr Darcet, has been employed in painting on porcelain *. Hitherto it has been found only in the primitive mountains, the Crapacks †, the Alpes (u), and the Pyrenees ‡. It has been found also in Brittany ‖ and in Cornwal.

* *Jour. de Min.* N° xv. 27.
† *Ibid*, N° xii. 51.
‡ *Jour. de Min.* N° xxxii. 614.
‖ *Ibid.*

GENUS I. OXYDS OF TITANIUM.

SPECIES 1. Red oxyd of Titanium.

Red shorl—Sagenite.

283
G. I. Oxyds Red oxyd of titanium.

This ore has been found in Hungary, the Pyrenees, the Alpes, and in Brittany in France. It is generally crystallized. The primitive form of its crystals, according to the observations of Mr Hauy, is a rectangular prism, whose base is a square; and the form of its molecules is a triangular prism, whose base is a right angled isosceles triangle, and the height is to any of the sides of the base about the right angle as $\sqrt{12}$ to $\sqrt{5}$, or nearly as 3 : 2 ¶. Sometimes the crystals of titanium are six sided, and sometimes four-sided, prisms, and often they are implicated together ‡.

¶ *Jour. de Min.* N° xv. 28. and xxxii. 615.
‡ Fig. 44.

Colour red or brownish red. Powder brick or orange red. Lustre 3. Transparency commonly 0; sometimes 1. Texture foliated. Hardness 9. Brittle. Sp. gr. from 4.18 * to 4.2469 †. Not affected by the mineral acids. When fused with carbonat of potass, and diluted with water, a white powder precipitates, heavier than the titanium employed. Before the blow-pipe it does not melt, but becomes opaque and brown. With microcosmic salt it forms a globule of glass, which appears black; but its fragments are violet. With borax it forms a deep yellow glass, with a tint of brown. With soda it divides and mixes, but does not form a transparent glass.

* *Klaproth.*
† *Vauquelin* and *Hecht.*

When pure, it is composed entirely of oxyd of titanium.

284
Menachanite.

SPECIES 2. Menachanite (x).

Oxyd of titanium combined with iron.

This substance has been found abundantly in the valley of Menachan in Cornwal; and hence was called menachanite by Mr Gregor, the discoverer of it. It is in small grains, like gunpowder, of no determinate shape, and mixed with a fine grey sand. Colour black. Easily pulverized. Powder attracted by the magnet. Sp. gr. 4.427. Does not detonate with nitre. With two parts of fixed alkali it melts into an olive coloured mass, from which nitric acid precipitates a white powder. The mineral acids only extract from it a little iron. Diluted sulphuric acid, mixed with the powder, in such a proportion that the mass is not too liquid, and then evaporated to dryness, produces a blue coloured mass. Before the blow-pipe does not decrepitate nor melt. It tinges microcosmic salt green; but the colour becomes brown on cooling: yet microcosmic salt does not dissolve it. Soluble in borax, and alters its colour in the same manner.

Metallic Ores.

According to the analysis of Mr Gregor, it is composed of

46	oxyd of iron,
45	oxyd of titanium.
91	with some silica and manganese †.

† *Mr Gregor, Jour. de Phys.* xxxix. 2. 152.

According to Mr Klaproth's analysis, it is composed of

51.00	oxyd of iron,
45.25	oxyd of titanium,
3.50	silica,
.25	oxyd of manganese.
100.00 ‡	

‡ *Beiträge*, i. 231.

A mineral, nearly of the same nature with the one just described, has been found in Bavaria. Its specific gravity, however, is only 3.7. According to the analysis of Vauquelin and Hecht, it is composed of

49	oxyd of titanium,
35	iron,
2	manganese,
14	oxygen combined with the iron and manganese
100 §	

§ *Jour. de Min.* No xix. 57.

285
Calcareo-siliceous ore of titanium.

SPECIES 3. Calcareo siliceous ore of titanium.

Oxyd of titanium combined with lime and silica—Titanite †.

This ore has hitherto been found only near Passau. It was discovered by Professor Hunger. It is sometimes massive, but more commonly crystallized in four sided prisms, not longer than one fourth of an inch.

† *Kirwan*, ii. 331.

Colour reddish, yellowish, or blackish brown; sometimes whitish grey. Powder whitish grey. Lustre waxy or nearly metallic, 2 to 3. Transparency from 0 to 2. Texture foliated. Hardness 9 or more. Brittle. Sp. gr. 3.510. Muriatic acid, by repeated digestion, dissolves one-third of it. Ammonia precipitates from this solution a clammy yellowish substance. Infusible by the blow-pipe, and also in a clay crucible; but in charcoal is converted into a black opaque porous slag.

According to the analysis of Klaproth, it is composed of

33	oxyd of titanium,
35	silica,
33	lime.

Ores of Tellurium.

ORDER XX. ORES OF TELLURIUM.

HITHERTO tellurium has only been found in Transylvania. It occurs in three different mines; that of Fatzbay, Offenbanya, and Nagyag, which are considered as gold mines, because they contain less or more of that metal. Its gangue is commonly quartz.

256 G. I. Alloys. White gold ore of Fatzbay.

GENUS I. ALLOYS OF TELLURIUM.

SPECIES 1. White gold ore of Fatzbay.

Alloy of tellurium and iron, with some gold.

This species is generally massive. Its colour is between tin white and lead grey. Lustre considerable, metallic. Texture granular *.

According to Klaproth's analysis, it is composed of

72.0 iron,
25.5 tellurium,
2.5 gold.

100.0 †

* *Ann. de Chim.* xxv. 327.

† *Ibid.* 280.

257 Graphic golden ore of Offenbanya.

SPECIES 2. Graphic golden ore of Offenbanya.

Tellurium alloyed with gold and silver.

This ore is composed of flat prismatic crystals; the arrangement of which has some resemblance to Turkish letters. Hence the name of the ore.

Colour tin white, with a tinge of brass yellow ‡. Lustre metallic, 3. Hardness 4 to 5. Brittle. Sp. gr. 5.723. Before the blow-pipe decrepitates, and melts like lead. Burns with a lively brown flame and disagreeable smell, and at last vanishes in a white smoke, leaving only a whitish earth ‖.

According to Klaproth's analysis, it is composed of

60 tellurium,
30 gold,
10 silver,

100 §

‡ *Ann de Chim* xxv. 328.

‖ *De Born, Kirwan's Min.* ii. 101.

The yellow gold ore of Nagyag would belong to this species were it not that it contains lead. Its composition, according to Klaproth's analysis, is as follows:

45.0 tellurium,
27.0 gold,
19.5 lead,
8.5 silver,

100.0 and an atom of sulphur *

§ *Ann. de Chim.* xxv. 280.

* *Ibid.*

288 Grey foliated gold ore of Nagyag.

SPECIES 3. Grey foliated gold ore of Nagyag.

This ore is found in plates, of different degrees of thickness, adhering to one another, but easily separable: these are sometimes hexahedral, and often accumulated so as to leave cells between them.

Colour deep lead grey, passing to iron black, spotted. Lustre metallic, moderate. Texture foliated; leaves slightly flexible †. Hardness 6. Sp. gr. 8.919. Stains the fingers. Soluble in acids with effervescence ‡.

According to Klaproth, it is composed of

50.0 lead,
33.0 tellurium,
8.5 gold,
7.5 sulphur,
1.0 silver and copper.

100.0 §

† *Klaproth, Ann. de Chim.* xxv. 329.

‡ *De Born, Kirwan's Min.* ii. 99.

Metallic

ORDER XXI. ORES OF CHROMUM.

CHROMUM has hitherto been found in too small quantities for its extensive application to the arts. Whenever it becomes plentiful, its properties will render it of great importance both to the dyer and painter. Nature has used it to colour some of her most beautiful mineral productions: And can art copy after a better model? Hitherto it has been found only in two places, near Ekaterinbourg in Siberia, and in the department of the Var in France. In the first of these places, and probably also in the second, its gangue is quartz.

GENUS I. SALTS OF CHROMUM.

SPECIES 1. Chromat of lead. 289 G. I. Salts. Chromat of lead.

Red lead ore of Siberia.

This singular mineral, which has now become scarce, is found in the gold mines of Beresof near Ekaterimbourg in Siberia, crystallized in four-sided prisms, sometimes terminated by four-sided pyramids, sometimes not.

Colour red, with a shade of yellow. Streak and powder a beautiful orange yellow. Lustre from 2 to 3. Transparency 2 to 3. Structure foliated. Texture compact. Fracture uneven. Hardness 5 to 4. Sp. gr. 6.0269 † to 5.75 ‡. Does not effervesce with acids. Before the blow-pipe decrepitates; some lead is reduced, and the mineral is converted to a black slag, which tinges borax green.

According to the analysis of Vauquelin, it is composed of

65.12 oxyd of lead,
34.88 chromic acid.

100.00 ‖.

† *Brisson.*
‡ *Bindheim.*
‖ *Jour. de Min.* N° xxxiv. 760.

SPECIES 2. Chromat of iron.

290 Chromat of iron.

This mineral, which has been found only near Gassin in the department of Var in France, is in irregular masses.

Colour brown, not unlike that of brown blende. Lustre metallic. Hardness moderate. Sp. gr. 4.0326. Melts with difficulty before the blow-pipe; to borax it communicates a dirty green. Insoluble in nitric acid. Melted with potass, and dissolved in water, the solution assumes a beautiful orange yellow colour.

It is composed of 63.6 chromic acid,
36.0 oxyd of iron.

99.6 †

† *Tassaert, Ann. de Chim.* xxxi. 220.

CHAP. IV. OF THE CHEMICAL ANALYSIS OF MINERALS.

291 Analysis of minerals.

THE progress which the art of analysing minerals has made within these last twenty years is truly astonishing. To separate five or six substances intimately combined together, to exhibit each of them separately, to ascertain the precise quantity of each, and even to detect the presence and the weight of substances which do not approach $\frac{1}{100}$th part of the compound, would, at no very remote period, have been considered as a hopeless, if not an impossible, task; yet this can now be done with the most rigid accuracy.

292 Begun by Margraff.

The first person who undertook the analysis of minerals was Margraff of Berlin. His attempts were indeed rude; but their importance was soon perceived by other chemists, particularly by Bergman and Scheele, whose

Analysis of Minerals.

whose industry and address brought the art of analysing minerals to a considerable degree of perfection.

But their methods, though they had very considerable merit, and, considering the state of the science, are wonderful proofs of the genius of the inventors, were often tedious and uncertain, and could not in all cases be applied with confidence. These defects were perceived by Mr Klaproth of Berlin, who applied himself to the analysis of minerals with a persevering industry which nothing could fatigue, and an ingenuity and accuracy which nothing could perplex. He corrected what was wrong, and supplied what was wanting, in the analytical method; invented new processes, discovered new instruments; and it is to his labours, more than to those of any other chemist, that the degree of perfection, to which the analysis of minerals has attained, is to be ascribed. Many improvements, however, were introduced by other chemists, especially by Mr Vauquelin, whose analyses in point of accuracy and ingenuity rival those of Klaproth himself.

293 Improved by Klaproth

294 And other chemists.

We shall, in this chapter, give a short description of the most perfect method of analysing minerals, as far as we are acquainted with it. We shall divide the chapter into four sections. In the first, we shall give an account of the instruments used in analyses; in the second, we shall treat of the method of analysing stones; in the third, of analysing combustibles; and in the fourth, of the analyses of ores.

Sect. I. *Of the Instruments of Analyses.*

295 Method of obtaining chemical agents pure.

I. The chemical agents, by means of which the analysis of minerals is accomplished, ought to be prepared with the greatest care, because upon their purity the exactness of the operation entirely depends. These agents are the three alkalies, both pure and combined with carbonic acid; the sulphuric, nitric, and muriatic acids; hydrosulphuret of potash and sulphurated hydrogen gas dissolved in water; prussic alkali, and a few neutral salts.

1. Potash and soda may be obtained pure, either by means of alcohol, or by the method described in the article Chemistry, n° 372. *Suppl.* These alkalies are known to be pure when their solution in pure water occasions no precipitate in lime and barytic water; when the precipitate which it produces in a solution of silver is completely dissolved by nitric acid; and, lastly, when saturated with carbonic acid it deposits no silica.

2. Ammonia is procured by distilling one part of muriat of ammonia with two parts of quicklime, and receiving the gas in a dish containing a quantity of pure water, equal in weight to the muriat employed. Its purity is known by the same tests which ascertain the purity of fixed alkalies.

3. The carbonats of potash and soda may be formed by dissolving the potash and soda of commerce in pure water, saturating the solution with carbonic acid, and crystallizing them repeatedly. When pure, these crystals effloresce in the air; and the precipitate which they occasion in solutions of barytes and of silver is completely soluble in nitric acid. Carbonat of ammonia is obtained by distilling together one part of muriat of ammonia and two parts of carbonat of lime.

4. The sulphuric acid of commerce often contains nitric acid, potash, lead, &c. It may be purified by distillation in a low cucurbite. The first portion, when it comes over, must be set aside; it contains the nitric acid. The other impurities remain behind in the cucurbite. Sulphuric acid, when pure, dissolves indigo without altering its colour, does not attack mercury while cold, and causes no precipitate in pure alkaline solutions.

Analysis of Minerals

5. Nitric acid often contains both sulphuric and muriatic acids. It is easily purified by throwing into it about three parts of litharge in fine powder for every 100 parts of the acid, allowing the mixture to remain for 24 hours, shaking it occasionally, and then distilling it. The sulphuric and muriatic acids combine with the lead, and remain behind in the retort. Pure nitric acid occasions no precipitate in the solutions of barytes and silver.

6. The muriatic acid of commerce usually contains sulphuric acid, oxymuriatic acid, and oxyd of iron. It may be purified by distillation with a little muriat of soda; taking care to set aside the first portion which comes over. When pure it causes no precipitate in the solution of barytes, nor of pure alkalies, and does not attack mercury while cold.

7. Hydrosulphuret of potash is made by saturating a solution of pure potash with sulphurated hydrogen gas; and water may be saturated with sulphurated hydrogen gas in the same manner. See Chemistry, n° 857. *Suppl.*

8. The method of preparing prussic alkali, oxalic acid, and the other substances used in analyses, has been already described in the article Chemistry, *Suppl.* it is unnecessary therefore to repeat it here.

II. Before a mineral is submitted to analysis, it ought to be reduced to an impalpable powder. This is by no means an easy task when the stone is extremely hard. It ought to be raised to a bright red or white heat in a crucible, and then instantly thrown into cold water. This sudden transition makes it crack and break into pieces. If these pieces are not small enough, the operation may be repeated on each till they are reduced to the proper size. These fragments are then to be beaten to small pieces in a polished steel mortar; the cavity of which should be cylindrical, and the steel pestle should fit it exactly, in order to prevent any of the stone from escaping during the act of pounding. As soon as the stone is reduced to pretty small pieces, it ought to be put into a mortar of rock crystal or flint, and reduced to a coarse powder. This mortar should be about four inches in diameter, and rather more than an inch in depth. The pestle should be formed of the same stone with the mortar, and care should be taken to know exactly the ingredients of which this mortar is composed. Klaproth's mortar is of flint. We have given its analysis in n° 32. of this article.

296 How to reduce the mineral to powder.

When the stone has been reduced to a coarse powder, a certain quantity, whose weight is known exactly, 100 grains for instance, ought to be taken and reduced to as fine a powder as possible. This is best done by pounding small quantities of it at once, not exceeding 10 grains. The powder is as fine as possible when it feels soft, adheres together, and as it were forms a cake under the pestle. It ought then to be weighed exactly. It will almost always be found heavier after being pounded than it was before; owing to a certain quantity of the substance of the mortar which has been rubbed off during the grinding and mixed with the powder.

Analysis of Minerals. der. This additional weight must be carefully noted; and after the analysis, a portion of the ingredients of the mortar, corresponding to it, must be subtracted.

297 Chemical vessels. III. It is necessary to have a crucible of pure silver, or, what is far preferable, of platinum, capable of holding rather more than seven cubic inches of water, and provided with a cover of the same metal. There should also be ready a spatula of the same metal about four inches long.

The dishes in which the solutions, evaporations, &c. are performed, ought to be of glass or porcelain. Those of porcelain are cheaper, because they are not so apt to break. Those which Mr Vauquelin uses are of porcelain; they are sections of spheres, and are glazed both within and without, except that part of the bottom which is immediately exposed to the fire.

Sect. II. *Analysis of Stones* (y).

298 Ingredients of stones. The only substances which enter into the composition of the simple stones, as far at least as analysis has discovered, are the six earths, silica, alumina, zirconia, glucina, lime, and magnesia; and the oxyds of iron, manganese, nickel, chromum, and copper (z). Seldom more than four or five of these substances are found combined together in the same stone: we shall suppose, however, in order to prevent unnecessary repetitions, that they are all contained in the mineral which we are going to analyse.

299 Method of decomposing stones. Let 100 or 200 grains of the stone to be analysed, previously reduced to a fine powder, be mixed with three times its weight of pure potass and a little water, and exposed in the silver or platinum crucible to a strong heat. The heat should at first be applied slowly, and the matter should be constantly stirred, to prevent the potass from swelling and throwing any part out of the crucible. When the whole water is evaporated, the mixture should be kept for half an hour or three quarters in a strong red heat.

If the matter in the crucible melts completely, and appears as liquid as water, we may be certain that the stone which we are analysing consists chiefly of silica; if it remains opaque, and of the consistence of paste, the other earths are most abundant; if it remains in the form of a powder, alumina is the prevalent earth. If the matter in the crucible be of a dark or brownish red colour, it contains oxyd of iron; if it is grass green, manganese is present; if it is yellowish green, it contains chromum.

When the crucible has been taken from the fire and wiped on the outside, it is to be placed in a capsule of porcelain, and filled with water. This water is to be renewed from time to time till all the matter is detached from the crucible. The water dissolves a part of the combination of the alkali with the silica and alumina of the stone, and if a sufficient quantity were used, it would dissolve the whole of that combination.

Muriatic acid is now to be poured in till the whole of the matter is dissolved. At first a flaky precipitate appears, because the acid combines with the alkali which kept it in solution. Then an effervescence takes place, owing to the decomposition of some carbonat of potass formed during the fusion. At the same time the flaky precipitate is redissolved; as is also that part of the matter which, not having been dissolved in the water, had remained at the bottom of the dish in the form of a powder. This powder, if it consists only of silica and alumina, dissolves without effervescence; but if it contains lime, an effervescence takes place.

If this solution in muriatic acid be colourless, we may conclude that it contains no metallic oxyd, or only a very small portion; if its colour be purplish red, it contains manganese; orange red indicates the presence of iron; and golden yellow the presence of chromum.

This solution is to be poured into a capsule of porcelain, covered with paper, and evaporated to dryness in a sand bath. When the evaporation is drawing towards its completion, the liquor assumes the form of jelly. It must then be stirred constantly with a glass or porcelain rod, in order to facilitate the disengagement of the acid and water, and to prevent one part of the matter from being too much, and another not sufficiently dried. Without this precaution, the silica and alumina would not be completely separated from each other.

When the matter is reduced almost to a dry powder, a large quantity of pure water is to be poured on it; and, after exposure to a slight heat, the whole is to be poured on a filter. The powder which remains upon the filter is to be washed repeatedly, till the water with which it has been washed ceases to precipitate silver from its solutions. This powder is the whole of *silica* which the stone that we are analysing c[illegible] It must first be dried between folds of blotting [illegible] then heated red hot in a platinum or silver cru[illegible] and weighed while it is yet warm. It ought to be a fine powder, of a white colour, not adhering to the fingers, and entirely soluble in acids. If it be coloured, it is contaminated with some metallic oxyd; and shews, that the evaporation to dryness has been performed at too high a temperature. To separate this oxyd, the silica must be boiled with an acid, and then washed and dried as before. The acid solution must be added to the water which passed through the filter, and which we shall denominate A. 300 How the silica is separated.

The watery solution A is to be evaporated till its quantity does not exceed 30 cubic inches, or nearly an English pint. A solution of carbonat of potass is then to be poured into it till no more matter precipitates. It ought to be boiled a few moments to enable all the precipitate to fall to the bottom. When the whole of the precipitate has collected at the bottom, the supernatant liquid is to be decanted off; and water being substituted in its place, the precipitate and water are to be thrown upon a filter. When the water has run off, the filter with the precipitate upon it is to be placed between folds of blotting paper. When the precipitate has acquired some consistence, it is to be carefully collected by an ivory knife, mixed with a solution of pure potass, and boiled in a porcelain capsule. If any alumina

(y) Part of this section is to be considered as an abstract of a treatise of Vauquelin on the analysis of stones, published in the *Annales de Chimie*, Vol. XXX. p. 66.

(z) Barytes has also been discovered in one single stone, the *staurolite*; but its presence in stones is so uncommon, that it can scarcely be looked for. The method of detecting it shall be noticed afterwards.

Analysis of Minerals.

301 And the alumina,

alumina or glucina be present, they will be dissolved in the potass; while the other substances remain untouched in the form of a powder, which we shall call B.

Into the solution of potass as much acid must be poured as will not only saturate the potass, but also completely redissolve any precipitate which may have at first appeared. Carbonat of ammonia is now to be added in such quantity that the liquid shall taste of it. By this addition the whole of the alumina will be precipitated in white flakes, and the glucina will remain dissolved, provided the quantity of carbonat of ammonia used be not too small. The liquid is now to be filtered, and the alumina which will remain on the filter is to be washed, dried, heated red hot, and then weighed. To see if it be really alumina, dissolve it in sulphuric acid, and add a sufficient quantity of sulphat or acetite of potass; if it be alumina, the whole of it will be converted into crystals of alum.

302 Glucina,

Let the liquid which has passed through the filter be boiled for some time, and the glucina, if it contains any, will be precipitated in a light powder, which may be dried and weighed. When pure, it is a fine, soft, very light, tasteless powder, which does not concrete when heated, as alumina does.

303 Lime,

The residuum B may contain lime, magnesia, and one or more metallic oxyds. Let it be dissolved in weak sulphuric acid, and the solution evaporated to dryness. Pour a small quantity of water on it. The water will dissolve the sulphat of magnesia, and the metallic sulphats; but the sulphat of lime will remain undissolved. Let it be heated red hot in a crucible, and weighed. The lime amounts to 0.41 of the weight.

Let the solution containing the remaining sulphats be diluted with a large quantity of water, let a small excess of acid be added, and then let a saturated carbonat of potass be poured in. The oxyds of chromum, iron, and nickel, will be precipitated, and the magnesia and oxyd of manganese will remain dissolved. The precipitate we shall call C.

304 Manganese,

Into the solution let a solution of hydrosulphuret of potass be poured, and the manganese will be precipitated in the state of a hydrosulphuret. Let it be calcined in contact with air, and weighed.

305 Magnesia,

The magnesia may then be precipitated by pure potass, washed, exposed to a red heat, and then weighed.

Let the residuum C be boiled repeatedly with nitric acid, then mixed with pure potass; and after being heated, let the liquid be decanted off.

306 Chromum,

Let the precipitate, which consists of the oxyds of iron and nickel, be washed with pure water; and let this water be added to the solution of the nitric acid and potass. That solution contains the chromum converted into an acid, Add to this solution an excess of muriatic acid, and evaporate till the liquid assumes a green colour; then add a pure alkali: The chromum precipitates in the state of an oxyd, and may be dried, and weighed.

307 Iron,

Let the precipitate, consisting of the oxyds of iron and nickel, be dissolved in muriatic acid; add an excess of ammonia: the oxyd of iron precipitates. Let it be washed, dried, and weighed.

308 And nickel.

Evaporate the solution, and the oxyd of nickel will also precipitate; and its weight may be ascertained in the same manner with the other ingredients.

The weights of all the ingredients obtained are now to be added together, and their sum total compared with the weight of the matter submitted to analysis. If the two are equal, or if they differ only by .03 or .04 parts, we may conclude that the analysis has been properly performed: but if the loss of weight be considerable, something or other has been lost. The analysis must therefore be repeated with all possible care. If there is still the same loss of weight, we may conclude that the stone contains some substance, which has either evaporated by the heat, or is soluble in water.

309 Method of detecting volatile bodies.

A fresh portion of the stone must therefore be broken into small pieces, and exposed in a porcelain crucible to a strong heat. If it contains water, or any other volatile substance, they will come over into the receiver; and their nature and weight may be ascertained.

If nothing comes over into the receiver, or if what comes over is not equal to the weight wanting, we may conclude that the stone contains some ingredient which is soluble in water.

310 Method of ascertaining whether stones contain potass.

To discover whether it contains *potass*, let the stone, reduced to an impalpable powder, be boiled five or six times in succession, with very strong sulphuric acid, applying a pretty strong heat towards the end of the operation, in order to expel the excess of acid; but taking care that it be not strong enough to decompose the salts which have been formed.

Water is now to be poured on, and the residuum, which does not dissolve, is to be
it becomes tasteless. The water
tered, and evaporated to dryness
any excess of acid which may be present. The salts are to be again dissolved in water; and the solution, after being boiled for a few moments, is to be filtered and evaporated to a consistence proper for crystallizing. If the stone contains a sufficient quantity of alumina, and if potass be present, crystals of alum will be formed; and the quantity of potass may be discovered by weighing them, it being nearly $\frac{1}{10}$th of their weight. If the stone does not contain alumina, or not in sufficient quantity, a solution of pure alumina in sulphuric acid must be added. Sometimes the alum,
present, does not appear for sever
and sometimes, when a great quan
sent, if the solution has been too much concentrated by evaporation, the sulphat of alumina prevents the alum from crystallizing at all. Care, therefore, must be taken to prevent this last source of error. The alum obtained may be dissolved in water, and barytic water poured into it as long as any precipitate forms. The liquor is to be filtered, and evaporated to dryness. The residuum will consist of potass and a little carbonat of potass. The potass may be dissolved in a little water. This solution, evaporated to dryness, gives us the potass pure; which may be examined and weighed.

Of soda.

If no crystals of alum can be obtained, we must look for some other substance than potass. The stone, for instance, may contain soda. The presence of this alkali may be discovered by decomposing the solution in sulphuric acid, already described, by means of ammonia. The liquid which remains is to be evaporated to dryness, and the residuum is to be calcined in a crucible. By this method, the sulphat of ammonia will be volatilized, and the soda will remain. It may be redissolved in water, crystallized, and examined.

If sulphuric acid does not attack the stone, as is often the case, it must be decomposed by fusion with soda,

Analysis of Minerals. da, in the same manner as formerly directed with potass. The matter, after fusion, is to be diluted with water, and then saturated with sulphuric acid. The solution is to be evaporated to dryness, the residuum again dissolved in water, and evaporated. Sulphat of soda will crystallize first; and by a second evaporation, if the stone contains potass and alumina, crystals of alum will be deposited.

The presence of potass may be discovered, by mixing with a somewhat concentrated solution of muriat of platinum, the salt obtained, either by decomposing the stone immediately by an acid, or by saturating with an acid the matter obtained by fusing the stone with soda. If any potass be present, a very red precipitate will be formed. This precipitate is a triple salt, composed of potass, muriatic acid, and oxyd of platinum. Ammonia, indeed, produces the same precipitate; but ammonia has not hitherto been discovered in stones.

312 Analysis of saline stones. In this manner may simple stones and aggregates be analysed. As to saline stones, their analysis must vary according to the acid which they contain. But almost all of them may be decomposed by one or other of two methods; of each of which we shall give an example.

I. Analysis of Carbonat of Strontites.

313 Of Carbonate. Klaproth analysed this mineral by dissolving 100 parts of it in diluted muriatic acid: during the solution, 30 parts of carbonic acid escaped. The solution crystallized in needles, and when dissolved in alcohol, burnt with a purple flame. Therefore it contained strontites. He dissolved a grain of sulphat of potass in six ounces of water, and let fall into it three drops of the muriatic solution. No precipitate appeared till next day. Therefore the solution contained no barytes; for if it had, a precipitate would have appeared immediately.

He then decomposed the muriatic acid solution, by mixing it with carbonat of potass. Carbonat of strontites precipitated. By the application of a strong heat, the carbonic acid was driven off. The whole of the earth which remained was dissolved in water. It crystallized; and when dried, weighed 69½ *.

* Klaproth's Beitrage, i. 260.

II. Analysis of Sulphat of Strontites.

Mr Vauquelin analysed an impure specimen of this mineral as follows:

314 Sulphate. On 200 parts of the mineral, diluted nitric acid was poured. A violent effervescence took place, and part of the mineral was dissolved. The undissolved portion, after being heated red hot, weighed 167. Therefore 33 parts were dissolved.

The nitric solution was evaporated to dryness: A reddish substance remained, which indicated the presence of oxyd of iron. This substance was redissolved in water, and some ammonia mixed with it; a reddish precipitate appeared, which, when dried, weighed 1, and was oxyd of iron. The remainder of the solution was precipitated by carbonat of potass. The precipitate weighed, when dried, 20, and possessed the properties of carbonat of lime. Therefore 200 parts of this mineral contain 20 of carbonat of lime, 1 of oxyd of iron, and the remainder of the 33 parts he concluded to be water.

The 167 parts, which were insoluble in nitric acid, were mixed with 500 parts of carbonat of potass, and 7000 parts of water, and boiled for a considerable time. The solution was then filtered, and the residuum washed and dried. The liquid scarcely effervesced with acids; but with barytes it produced a copious precipitate, totally indissoluble in muriatic acid. Therefore it contained sulphuric acid.

The undissolved residuum, when dried, weighed 129 parts. It dissolved completely in muriatic acid. The solution crystallized in needles; when dissolved in alcohol, it burnt with a purple flame; and, in short, had all the properties of muriat of strontites. Therefore these 129 parts were carbonat of strontites. Now, 100 parts of this carbonat contain 30 of carbonic acid; therefore 129 contain 38.7. Therefore the mineral must contain in 200 parts 90.3 of strontites.

Now, the insoluble residuum of 167 parts was pure sulphat of strontites; and we have seen that it contained 90.3 of strontites. Therefore the sulphuric acid must amount to 76.7 parts †.

† Jour. de Min. No xxxvi. p. 1.

Nearly in the same manner as in the first of these examples, may the analysis of carbonat of lime and barytes be performed; and nearly in the same manner with the second, we may analyse the sulphats of lime and barytes.

315 Phosphats. Phosphat of lime may be dissolved in muriatic acid, and the lime precipitated by sulphuric acid, and its quantity ascertained by decomposing the sulphat of lime obtained. The liquid solution may be evaporated to the consistence of honey, mixed with charcoal powder, and distilled in a strong heat. By this means phosphorus will be obtained. The impurities with which the phosphat may be contaminated will partly remain undissolved, and be partly dissolved, in muriatic acid. They may be detected and ascertained by the rules laid down in the second section of this chapter.

316 Fluats. The fluat of lime may be mixed with sulphuric acid and distilled. The fluoric acid will come over in the form of gas, and its weight may be ascertained. What remains in the retort, which will consist chiefly of sulphat of lime, may be analysed by the rules already laid down.

317 And borats. The borat of lime may be dissolved in nitric or sulphuric acid. The solution may be evaporated to dryness, and the boracic acid separated from the residuum by means of alcohol, which will dissolve it without acting on any of the other ingredients. The remainder of the dry mass may be analysed by the rules laid down in Sect. II. of this Chapter.

Sect. III. *Of the Analysis of Combustibles.*

The only combustibles of whose analysis it will be necessary to speak are coals and sulphur; for the method of analysing the diamond and oil has already been given in the article Chemistry, *Suppl.*

318 Earths of coal how examined. Coal is composed of carbon, bitumen, and some portion of earth. The earths may be detected by burning completely a portion of the coal to be analysed. The ashes which remain after incineration consist of the earthy part. Their nature may be ascertained by the rules laid down in Sect. II. of this Chapter.

For the method of ascertaining the proportion of carbon and bitumen in coal, we are indebted to Mr Kirwan.

319 Method of detecting the relative proportions of charcoal and bitumen. When nitre is heated red hot, and charcoal is thrown on it, a violent detonation takes place; and if the quantity of charcoal be sufficient, the nitre is completely decomposed. Now, it requires a certain quantity of pure carbon

Analysis of Minerals.

carbon to decompose a given weight of nitre. From the experiments of Lavoisier, it follows, that when the detonation is performed in close vessels under water, 13.21 parts of charcoal are capable of decomposing 100 parts of nitre*. But when the detonation is performed in an open crucible, a smaller proportion of charcoal is necessary, because part of the nitre is decomposed by the action of the surrounding air. Scheele found, that under these circumstances 10 parts of plumbago were sufficient to decompose 96 parts of nitre, and Mr Kirwan found, that nearly the same quantity of charcoal was sufficient for producing the same effect.

Macquer long ago observed, that no volatile oily matter will detonate with nitre, unless it be previously reduced to a charcoal; and that then its effect upon nitre is precisely proportional to the charcoal which it contains †. Mr Kirwan, upon trying the experiment with *vegetable pitch* and *maltha*, found, that these substances did not detonate with nitre, but merely burn upon its surface with a white or yellow flame; and that after they were consumed, nearly the same quantity of charcoal was necessary to decompose the nitre which would have been required if no bitumen had been used at all ‡. Now coals are chiefly composed of charcoal and bitumen. It occurred therefore to Mr Kirwan, that the quantity of charcoal which any coal contains may be ascertained by detonating it with nitre: For since the bitumen of the coal has no effect in decomposing nitre, it is evident that the detonation and decomposition must be owing to the charcoal of the coal; and that therefore the quantity of coal necessary to decompose a given portion of nitre will indicate the quantity of carbon which it contains: and the proportion of charcoal and earth which any coal contains being ascertained, its bituminous part may be easily had from calculation.

The crucible which he used in his experiments was large; it was placed in a wind furnace at a distance from the flue, and the heat in every experiment was as equal as possible. The moment the nitre was red hot, the coal, previously reduced to small pieces of the size of a pin head, was projected in portions of one or two grains at a time, till the nitre would no longer detonate; and every experiment was repeated several times to ensure accuracy.

He found, that 480 grains of nitre required 50 grains of Kilkenny coal to decompose it by this method. Therefore 10 grains would have decomposed 96 of nitre; precisely the quantity of charcoal which would have produced the same effect. Therefore Kilkenny coal is composed almost entirely of charcoal.

Cannel coal, when incinerated, left a residuum of 3.12 in the 100 parts of earthy ashes. 66.5 grains of it were required to decompose 480 grains of nitre; but 50 parts of charcoal would have been sufficient: therefore 66.5 grains of cannel coal contain 50 grains of charcoal, and 2.08 of earth; the remaining 14.42 grains must be bitumen. In this manner may the composition of any other coal be ascertained.

320
Method of analysing sulphur.

As for sulphur, in order to ascertain any accidental impurities with which it may be contaminated, it ought to be boiled in thirty times its weight of water, afterwards in diluted muriatic acid, and lastly in diluted nitro-muriatic acid. These substances will deprive it of all its impurities without acting on the sulphur itself, at least if the proper cautions be attended to. The sulphur may then be dried and weighed. The deficiency in weight will mark the quantity of the substances which contaminate the sulphur. The solutions may be evaporated and examined, according to the rules laid down in the second and fourth sections of this chapter.

Sect. IV. *Of the Analysis of Ores.*

321
No general method of analysing ores.

The method of analysing ores must vary considerably, according to the metals which they are suspected to contain. A general method, therefore, of analysing ores would be of no use, even if it could be given, because it would be too complicated ever to be practised. We shall content ourselves with exhibiting a sufficient number of the analyses of ores, to take in most of the cases which can occur He who wishes for more information on the subject, may consult the treatise of Bergman on the *Analyses of Ores*; Mr Kirwan's treatise on the same subject; and, above all, he ought to study the numerous analyses of ores which have been published by Mr Klaproth.

I. Analysis of Red Silver Ore.

322
Method of analysing red silver ore.

Mr Vauquelin analysed this ore as follows:

He reduced 100 parts of it to fine powder, poured over it 500 parts of nitric acid previously diluted with water, and applied a gentle heat to the mixture. The colour of the powder, which before the mixture with nitric acid was a deep purple, became gradually lighter, till at last it was pure white. During this change no nitrous gas was extricated; hence he concluded, that the metals in the ore were in the state of oxyds.

When the nitric acid, even though boiled gently, did not appear to be capable of dissolving any more of the powder, it was decanted off, and the residuum, after being carefully washed, weighed 42.06.

Upon these 42.06 parts concentrated muriatic acid was poured; and by the application of heat, a considerable portion was dissolved. The residuum was repeatedly washed with muriatic acid, and then dried. Its weight was 14.6666. One portion of these 14.6666 parts, when thrown upon burning coals, burnt with a blue flame and sulphureous smell. Another portion sublimed in a close vessel without leaving any residuum. In short, they had all the properties of sulphur. Therefore 100 parts of red silver ore contain 14.6666 of sulphur.

The muriatic acid solution was now diluted with a great quantity of water; it became milky, and deposited a white flaky powder, which when washed and dried weighed 21.25. This powder, when heated with tartar in a crucible, was converted into a bluish white brittle metal, of a foliated texture, and possessing all the other properties of antimony. Red silver ore therefore contains 21.25 of oxyd of antimony.

The solution in nitric acid remained now to be examined. When muriatic acid was poured into it, a copious white precipitate appeared, which, when washed and dried, weighed 72.66. It had all the properties of muriat of silver. According to Mr Kirwan's tables, 72.66 of muriat of silver contain 60.57 of oxyd of silver. Therefore red silver ore, according to this analysis, is composed of

60.57	oxyd of silver,
21.25	oxyd of antimony,
14.66	sulphur.
96.48	

The

The loss, which amounts to 3.52 parts, is to be ascribed to unavoidable errors which attend such experiments.

II. Antimoniated Silver Ore.

323 Analysis of antimoniated silver ore.

Klaproth analysed this ore as follows:

On 100 parts of the ore, reduced to a fine powder, he poured diluted nitric acid, raised the mixture to a boiling heat, and after pouring off the acid, added new quantities repeatedly, till it would dissolve nothing more. The residuum was of a greyish yellow colour, and weighed, when dry, 26.

These 26 parts he digested in a mixture of nitric and muriatic acid; part was dissolved, and part still remained in the form of a powder. This residuum, when washed and dried, weighed 13 parts. It had the properties of sulphur; and when burnt, left a residuum of one part, which had the properties of silica. Antimoniated silver ore, therefore, contains, in the 100 parts, 12 parts of sulphur and 1 of silica.

When the nitro-muriatic solution was diluted with about 20 times its weight of water, a white precipitate appeared; which, when heated to redness, became yellow. Its weight was 13. No part evaporated at a red heat: therefore it contained no arsenic. On burning coals, especially when soda was added, part was reduced to a metal, having the properties of antimony; and in a pretty high heat, the whole evaporated in a grey smoke. These 13 parts were therefore oxyd of antimony: They contain about 10 parts of metallic antimony; and as the state of oxyd was produced by the action of the nitric acid, we may conclude, that antimoniated silver ore contains 10 parts of antimony.

The nitric acid solution remained still to be examined. It was of a green colour. When a solution of common salt was poured in, a white precipitate was obtained, which possessed the properties of muriat of silver. When dried, it weighed 87.75 parts; and when reduced, 65.81 parts of pure silver were obtained from it. Antimoniated silver ore, therefore, contains 65.81 of silver.

Into the nitric acid solution, thus deprived of the silver, he dropped a little of the solution of sulphat of soda; but no precipitate appeared. Therefore it contained no lead.

He supersaturated it with pure ammonia, on which a grey precipitate appeared. When dried, it weighed 5 parts. This, on burning coals, gave out an arsenical smell. It was redissolved in nitric acid; sulphurated alkali occasioned a smutty brown precipitate; and prussic alkali a prussian blue, which, after torrefaction, was magnetic. Hence he concluded, that these 5 parts were a combination of iron and arsenic acid.

The nitric solution, which had been supersaturated with ammonia, was blue; he therefore suspected that it contained copper. To discover this, he saturated it with sulphuric acid, and put into it a polished plate of iron. The quantity of copper was so small, that none could be collected on the iron.

III. Grey Copper Ore.

324 Analysis of grey copper ore.

Klaproth analysed this ore as follows:

Three hundred grains of it, not completely freed from its matrix, were reduced to a fine powder; four times their weight of nitric acid was poured on them, and the whole was digested. The acid was then poured off, and an equal quantity again digested on the residuum. The two acid solutions were mixed together. The residuum was of a yellowish grey colour, and weighed 188 grains.

On this residuum six times its weight of muriatic acid was boiled. The residuum was washed, first with muriatic acid, and afterwards with alcohol, and the washings added to the muriatic acid solution. The residuum, when dried, weighed 105.5 grains. Part of it burned with a blue flame; and was therefore sulphur. The residuum amounted to 80.25 grains, and had the properties of silica. When melted with black flux, about $\frac{3}{4}$ths of a grain of silver were obtained from it. Thus 300 parts of grey copper ore contain 25.25 gr. of sulphur, and 79.5 of silica.

The muriatic acid solution, which was of a light yellow colour, was concentrated by distillation, a few crystals of muriat of silver appeared in it, which contained about $\frac{1}{4}$th grain of silver. The solution, thus concentrated, was diluted with a great quantity of water; a white precipitate was deposited, which, when dried, weighed 97.25 grains. It possessed the properties of oxyd of antimony, and contained 75 grains of antimony. Therefore 300 grains of grey copper ore contain 70 of antimony.

The nitric acid solution was of a clear green colour. A solution of common salt occasioned a white precipitate, which was muriat of silver, and from which 31.5 grains of silver were obtained.

A little sulphat of potass, and afterwards sulphuric acid, were added, to see whether the solution contained lead; but no precipitate appeared.

The solution was then supersaturated with ammonia; a loose fleaky brownish red precipitate appeared, which, when heated to redness, became brownish black; and weighed $9\frac{1}{4}$th grains. This precipitate was dissolved in muriatic acid; half a grain of matter remained undissolved, which was silica. The muriatic acid solution, when prussic alkali was added, afforded a blue precipitate; and soda afterwards precipitated 1.5 grains of alumina. Therefore 300 grains of grey copper ore contain 7.25 grains of iron, and 1.5 of alumina.

Into the nitric solution supersaturated with ammonia, and which was of an azure blue colour, a polished plate of iron was put: By this method 69 grains of copper were obtained.

IV. Sulphuret of Tin.

Klaproth analysed this ore as follows*:

On 120 grains of the ore reduced to powder, six times their weight of nitro muriatic acid, composed of 2 parts of muriatic, and 1 of nitric acid, were poured. 325 Analysis of sulphuret of tin.

There remained undissolved 43 grains, which had the appearance of sulphur; but containing green spots, was suspected not to be pure. After a gentle combustion, 13 grains remained; 8 of which were dissolved in nitro-muriatic acid, and added to the first solution. The remaining 5 were separated by the filtre, and heated along with wax. By this method about a grain of matter was obtained, which was attracted by the magnet; and which therefore was iron. The residuum weighed 3 grains, and was a mixture of alumina and silica. Thus 120 grains of sulphuret of tin contain 30 grains of sulphur, 1 of iron, and 3 of alumina and silica.

* *Observations on the Fossils of Cornwall*, p. 48.

Analysis of Minerals.

The nitro-muriatic solution was completely precipitated by potash. The precipitate was of a greyish green colour. It was washed and dried, and again dissolved in diluted muriatic acid. Into the solution a cylinder of pure tin was put, which weighed exactly 217 grains. The solution became gradually colourless, and a quantity of copper precipitated on the cylinder of tin, which weighed 44 grains. To see whether it was pure, a quantity of nitric acid was digested on it; the whole was dissolved, except one grain of tin. Therefore 120 grains of sulphuret of tin contains 43 grains of copper.

The cylinder of tin now weighed only 128 grains; so that 89 grains had been dissolved. Into the solution a cylinder of zinc was put; upon which a quantity of tin precipitated. When washed and dried, it weighed 130 grains. The tin he melted with tallow and powdered charcoal; and when cold, he washed off the charcoal. Among the tin globules were found some black flocculi of iron, which weighed one grain. Deducting this grain, and the 89 grains of the tin cylinder which had been dissolved, we see that the 120 grains of sulphuret of tin contained 40 grains of tin besides the grain which had been detected in the copper.

V. Plumbiferous Antimoniated Silver Ore.

316 Analysis of plumbiferous antimoniated silver ore.

Klaproth analysed this ore as follows:

He digested 400 grains of it, reduced to a fine powder, first in five times its weight of nitric acid, and then in twice its weight of the same acid. He then diluted this last portion of acid with eight times its weight of water, and continued the digestion. The undissolved residuum, when washed and dried, weighed 326 grains.

On this residuum he boiled muriatic acid repeatedly. The solution, on cooling, deposited acicular crystals. These he carefully separated, and put by. The undissolved residuum weighed 51 grains. It had the properties of sulphur. When burned, it left one grain of silica.

The muriatic acid solution was concentrated to half its former bulk by distillation: this made it deposite more acicular crystals. He continued the distillation as long as any crystals continued to appear. He then collected the whole of these crystals together. They had the properties of muriat of lead. When mixed with twice their weight of black flux, and heated in a crucible lined with charcoal, they yielded $160\frac{1}{8}$ grains of lead.

Sulphuret of ammonia was now added to the muriatic acid solution; an orange-coloured precipitate appeared, which shewed that the solution contained antimony. It was precipitated by a copious effusion of water, and by soda. The oxyd of antimony being reduced to a mass with Spanish soap, mixed with black flux, and heated in a lined crucible, yielded 28.5 grains of antimony.

Into the nitric acid solution, obtained by the first part of the process, a solution of muriat of soda was dropped; a white precipitate was deposited, and over it acicular crystals. These crystals he dissolved, by pouring boiling water on the precipitate. The water was added to the nitric acid solution. The white precipitate was muriat of silver: when heated with twice its weight of soda, it yielded 81.5 grains of silver.

He now concentrated the nitric acid solution by evaporation; and then adding a solution of sulphat of soda, a white precipitate was obtained, which had the properties of sulphat of lead, and weighed 43 grains. It contained 32 grains of pure lead.

Analysis of Mineral.

He now poured ammonia into the solution; a pale brown precipitate was obtained, which weighed 40 grains, and which appeared to consist of oxyd of iron and alumina. He redissolved it in nitric acid, precipitated the iron by prussic alkali, and the alumina by soda. The alumina, after being heated to redness, weighed 28 grains; consequently the oxyd of iron was 12 grains, which is equivalent to 9 grains of iron.

VI. Molybdat of Lead.

Mr Hatchett analysed this ore as follows †:

310

317 Analysis of molybdat

On 250 grains of the ore, reduced to a fine powder, he poured an ounce of strong sulphuric acid, and digested the mixture in a strong heat for an hour. When the solution was cool, and had settled, he decanted it off, and washed the undissolved powder with pure water, till it came away tasteless. This operation was repeated twice more; so that three ounces of sulphuric acid were used. All these solutions were mixed together, and filtered.

Four ounces of a solution of carbonat of soda were poured upon the powder which remained undissolved, and which consisted of sulphat of lead. The mixture was boiled for an hour, and then poured off. The powder was then washed, and diluted nitric acid poured on it: The whole was dissolved, except a little [illegible] powder, which, when washed, and dried on a filter by the heat of boiling water, weighed seven-tenths of a grain. It possessed the properties of silica.

The nitric acid solution was saturated with pure soda; a white precipitate was obtained, which, when washed, and dried for an hour in a heat rather below redness, weighed 146 grains. It possessed the properties of oxyd of lead.

To see whether this oxyd of lead contained any iron, it was dissolved in diluted nitric acid, and the lead precipitated by sulphuric acid. The solution was then saturated with ammonia; a brown powder precipitated, which, when dried, weighed one grain, and had the properties of oxyd of iron.

The sulphuric acid solution was of a pale blue colour: It was diluted with 16 times its weight of pure water, and then saturated with ammonia. It became of a deep blue colour, and appeared turbid. In 24 hours a pale yellow precipitate subsided, which, when collected on a filter, and dried by a boiling water heat, weighed 4.2 grains. Its colour was yellowish brown. Muriatic acid dissolved it, and prussiat of potash precipitated it from its solution in the state of prussian blue. It was therefore oxyd of iron.

The sulphuric acid solution, saturated with ammonia, was gradually evaporated to a dry salt. This salt was a mixture of molybdat of ammonia and sulphat of ammonia. A strong heat was applied, and the distillation continued till the whole of the sulphat of ammonia was driven off; and to be certain that this was the case, the fire was raised till the retort became red hot. The residuum in the retort was a black blistered mass; three ounces of nitric acid, diluted with water, were poured upon it, and distilled off. The operation was again repeated.

† Phil. Tran.

peated. By this method the oxyd of molybdenum was converted into a yellow powder, which was yellow acid of molybdenum. It weighed 95 grains.

VII. Grey Ore of Manganese.

Analysis of grey ore of manganese.

Mr Vauquelin analysed this ore as follows ‡ :

When 200 grains of it were exposed to a strong heat in a retort, there came over 10 grains of water, and 18 cubic inches of oxygen gas, mixed with a little carbonic acid gas. The mineral now weighed only 176 grains. Therefore the weight of the gas was 14 grains.

On 200 grains of the same mineral muriatic acid was poured, and heat applied. 75 cubic inches of oxy muriatic acid gas came over, which, though mixed with some carbonic acid gas, enflamed metals when reduced to powder. When no more gas came over, the residuum was boiled. The whole was dissolved, except a white powder, which weighed 12 grains, and which possessed the properties of silica.

Carbonat of potass was poured into the solution; a white precipitate was obtained, which became black by exposure to the air, and weighed 288 grains. Strong nitric acid was boiled on it repeatedly to dryness. It became of a deep black colour, and, when well washed with water and dried, weighed 164 grains. This powder was black oxyd of manganese.

To see whether it contained iron, nitric acid, with a little sugar, was poured upon it, and digested on it. The acid dissolved it completely. Therefore no oxyd of iron was present.

Into the water with which the black oxyd of manganese had been washed, carbonat of potass was poured; a white powder precipitated, which, when dried, weighed 149 grains, and which possessed the poperties of carbonat of lime.

‡ Jour. de Min. xvii. p. 12.

VIII. Wolfram.

319
Analysis of wolfram.

Messrs Vauquelin and Hecht analysed this mineral as follows:

On 200 parts of Wolfram in powder, three times its weight of muriatic acid were poured, and the mixture boiled for a quarter of an hour: a yellow powder appeared, and the solution was of a brown colour. The acid was allowed to cool, and then carefully decanted off, and the residuum washed. The residuum was then digested for some hours with ammonia, which dissolved a part of it. The residuum was washed, and new muriatic acid again poured over it; then the residuum was digested with ammonia, as before: and the operation was continued till the whole wolfram was dissolved.

All the ammoniacal solutions being joined together, were evaporated to dryness, and the salt which remained was calcined: a yellow powder was obtained; it weighed 134 grains, and was yellow acid of tungsten.

Into the muriatic acid solutions, which were all mixed together, a sufficient quantity of sulphuric acid was poured to decompose all the salts. The solution was then evaporated to dryness; and the salts which were obtained by this evaporation were redissolved in water. A white powder remained, which weighed three grains, and which possessed the properties of silica.

The excess of acid of the solution was saturated with carbonat of potass; the liquor became brown, but nothing precipitated. When boiled, a red powder precipitated, and the brown colour disappeared. The addition of more carbonat of potass caused a farther precipitation of a yellowish powder. This precipitate consisted of the oxyds of iron and manganese combined. Nitric acid was distilled off it repeatedly; it was then boiled in acetous acid. The acetous solution was precipitated by potass. Nitric acid was again distilled off it, and it was again boiled in acetous acid. This process was repeated till nitric acid produced no further change. The different powders which could not be dissolved in the acetous acid were collected, mixed with a little oil, and heated red hot. The powder became black, and was attracted by the magnet. It was therefore oxyd of iron. It weighed 36 grains.

The acetous solution contained the oxyd of manganese: It was precipitated by an alkali, and, when dried, weighed 12.5 grains.

IX. Oxyd of Titanium and Iron.

330
Analysis of oxyd of titanium and iron.

Vauquelin analysed this ore as follows:

A hundred parts of the ore, reduced to a fine powder, and mixed with 400 parts of potass, were melted in a silver crucible for an hour and a half. When cool, the mixture was diluted with water; a powder remained of a brick red colour, which, when washed and dried, weighed 124 parts.

The watery solution had a fine green colour; when an excess of muriatic acid was added, it became red. By evaporation the liquor lost its colour. When evaporated to dryness, a salt remained, which was totally dissolved by water. From this solution carbonat of potass precipitated two parts, which had the properties of oxyd of manganese.

The 124 parts of residuum were boiled in a solution of pure potass for an hour. The solution was saturated with an acid, filtered, and carbonat of potass added, which precipitated three parts. These had the properties of oxyd of titanium.

The remainder of the 124 parts of residuum, which still was undissolved, was boiled with diluted muriatic acid. The liquor became yellow, and deposited 46 parts of a white powder, with a tint of red. This powder was soluble in sulphuric and muriatic acids: from these solutions, it was precipitated of a brick red colour by the infusion of nut galls; of a green colour by sulphuret of ammonia and prussiat of potass; and of a white colour by carbonat of potass and pure ammonia. A rod of tin made these solutions red; a rod of zinc made them violet. These 46 parts, therefore, are oxyd of titanium.

The muriatic solution, from which these 46 parts were deposited, formed, with prussiat of potass, a prussian blue; and ammonia precipitated from it 50 parts, which had the properties of yellow oxyd of iron.

I N D X.

Petrilite,

Mirabeau. MIRABEAU (Honnoré Gabriel, Comte de), well known both by his writings, and the active part which he took in bringing about the French revolution, was born in 1749 of a noble family. Throughout life, he diſplayed a ſpirit averſe from every reſtraint, and was one of thoſe unhappy geniuſes in whom the moſt brilliant talents ſerve only as a ſcourge to themſelves and all around them. It is told by his democratical panegyriſts, as a wonderful proof of family tyranny under the old government, that not leſs than 67 *lettres de cachet* had been obtained by Mirabeau the father againſt this ſon and others of his relatives. This ſtory, if true, proves, with at leaſt equal force, what many anecdotes confirm, that, for his ſhare of them, the ſon was not leſs indebted to his own ungovernable diſpoſition than to the ſeverity of his parent. He was indeed a monſter of wickedneſs. Debauchery, gaming, impiety, and every kind of ſenſuality, were not enough for him. He was deſtitute of decency in his vices; and to ſupply his expences, ſcrupled not to perform tricks which would diſgrace a thief catcher. His father and mother diſagreeing, commenced a proceſs of ſeparation; when Mirabeau, juſt liberated from priſon for a groſs miſdemeanor, was in want of money. He went to his father, ſided with him againſt his mother, on whom he poured a torrent of invective; and, for [illegible] guineas, wrote his father's memorial for the court. He then went to his mother; and by a ſimilar conduct got the ſame ſum from her; and both memorials were preſented. That the father of ſuch a man ſhould frequently get him ſhut up in priſon, can excite no ſurpriſe; for confinement only could withhold him from the perpetration of crimes.

The talents of Mirabeau led him frequently to employ his pen; and his publications form the chief epochas of his life. His firſt publication was, 1. *Eſſai ſur le Deſpotiſme*, "An Eſſay on Deſpotiſm," in 8vo. Next, in one of his confinements, he wrote, 2. a work in 2 vols 8vo, *On Lettres de Cachet*. 3. *Conſiderations ſur l'Ordre de Cincinnatus*, 8vo. A remonſtrance againſt the order of Cincinnatus, propoſed at one time to be eſtabliſhed in America. The public opinion in America favoured this remonſtrance, and it proved effectual. 4. His next work was in favour of the Dutch, when Joſeph II. demanded the opening of the Scheldt, in behalf of the Brabançons. It is entitled, *Doutes ſur la Liberté de l'Eſcaut*, 8vo. 5. *Lettre à l'Empereur Joſeph II. ſur ſon Reglement concernant l'Emigration*; a pamphlet of forty pages, in 8vo. 6. *De la Caiſſe d'Eſcompte*; a volume in 8vo, written againſt that eſtabliſhment. 7. *De la Banque d'Eſpagne*, 8vo; a remonſtrance againſt eſtabliſhing a French bank in Spain. A controverſy

controversy arising upon this subject, he wrote again upon it. 8. Two pamphlets on the monopoly of the water company in Paris.

Soon after the publication of these works, he was sent in a public character to the court of Berlin; where he conducted the king's affairs just as he had formerly done those of his father and mother, fully ready to sacrifice all parties, and to sell himself to the highest bidder. With such a disposition, he could not long avoid the notice of the Prussian illuminees; and Nicolai Biester, Gedicke, and Leuchsenring, soon became his constant companions. At Brunswick he met with Mauvillon, the worthy disciple of Philo Knigge, and at that time a professor in the Caroline college. This was the man who initiated the profligate Marquis in the last mysteries of illuminism.

Mirabeau was still at Berlin when Frederick II. died. That monarch, as is well known, was a naturalist, who, holding this life for his all, encouraged the propagation of infidelity in his dominions, from which resulted the very worst consequences to the peace of society. Of this truth his successor Frederick William was duly sensible; and determined to support the church establishment in the most peremptory manner, consistent with the principles of religious toleration. He published, therefore, soon after his accession, an edict on religion, which is a model worthy of imitation in every country; but it was attacked with the greatest virulence in numberless publications. It was called an unjustifiable tyranny over the consciences of men; the dogmas supported by it were termed absurd superstitions; the king's private character and his religious opinions were ridiculed and scandalously abused. The most daring of these attacks was a collection of anonymous letters on the constitution of the Prussian states, universally believed to be the composition of Mirabeau, who certainly wrote a French translation, with a preface and notes more impudent than the work itself. The monarch is declared to be a tyrant; the people of the Prussian dominions are addressed as a parcel of tame wretches, crouching under oppression; and the inhabitants of Silesia, represented as still in a worse condition, are repeatedly called upon to rouse themselves, and assert their rights.

About this time he published, 9. An *Essai sur la Secte des Illuminés;* one of the strangest and most impudent books that ever appeared. In it he describes a sect existing in Germany, called the *Illuminated;* and says, that they are the most absurd and gross fanatics imaginable, waging war with every appearance of reason, and maintaining the most *ridiculous superstitions.* He gives some account of these, and of their rituals and ceremonies, as if he had seen them all; yet no such society as he describes ever existed: and Mirabeau employed his powers of deception, merely to screen from observation the real *illuminati,* by holding out to the rulers of states this *ignis fatuus* of his own brain. For a while the essay certainly contributed to blind the eyes of the German princes; and Nicolai, with others of the junto, adopting the whim, called Mirabeau's fanatics *Obscuranten,* and joined with him in placing on the list of *Obscuranten* several persons whom they wished to make ridiculous.

Long before his initiation in the mysteries of illuminism, Mirabeau had been acquainted with all the revolutionary powers of the masonic lodges; nor did he, when initiated, undervalue those which flowed, or might flow, from Weishaupt's inventive genius. On his return to France, he began to introduce the new mysteries among some of his masonic brethren. His first associate was the Abbé Talleyrand de Perigord, who had already begun to act the part of Judas in the first order of the church. But to have only introduced the mysteries was not sufficient for the Marquis; he would have teachers come from Germany, who were better versed than he was in the illuminizing arts. Well acquainted with the reasons that had induced the chiefs of the order to defer the conversion of France, he found means to convince them, that the time was now come for the accomplishment of their views; and at his request a deputation was sent by Spartacus to illuminize that great kingdom. See ILLUMINATI, n° 40, 41, *Suppl.*

When the assembly of Notables was convened at Paris, Mirabeau foretold that it would soon be followed by a meeting of the States; and at that period he published a volume against the stockjobbing, then carried to a great height, intituled, 10. *Denonciation de l'agiotage au Roi, et a l'Assemblée de Notables,* 8vo. A *lettre de cachet* was issued against him in consequence of this publication; but he eluded pursuit, and published a pamphlet as a sequel to the book. His next work was against M. Necker, 11. *Lettre á M. de Cretelle, sur l'Administration de M. Necker,* a pamphlet in 8vo. 12. A volume, in 8vo. against the Stadtholdership: *Aux Bataves, sur le Stadthouderat.* 13. *Observations sur la maison de force appellé Bicetre,* an 8vo pamphlet. 14. Another tract, intitled, *Conseils a un jeune Prince qui sent la nécessité de refaire son education.* 15. He now proceeded to a larger and more arduous work than any he had yet published, on the Prussian monarchy under Frederick the Great: *De la Monarchie Prussienne sous Frédéric le Grand,* 4 vols, 4to, or eight in 8vo. In this work, he undertakes to define precisely how a monarchy should be constituted. When the orders were issued for convening the States general, Mirabeau returned into Provence; and at the same time published, 16. *Histoire Secrette de la Cour de Berlin,* two volumes of letters on the Secret History of the Court of Berlin. This work was condemned by the parliament of Paris, for the unreserved manner in which it delivered the characters of many foreign princes. As the elections proceeded, he offered himself a candidate in his own order at Aix; but he was so abhorred by the noblesse, that they not only rejected him, but even drove him from their presence. This affront settled his measures, and he determined on their ruin. He went to the commons, disclaimed his being a gentleman, set up a little shop in the market-place of Aix, where he sold trifles; and now, fully resolved what line he should pursue, he courted the commons, by joining in all their excesses against the noblesse, and was at last returned a member of the assembly.

In consequence of this, he went to Paris; where the part he took was active, and such as tended, in general, to accelerate all the violences of the revolution. He now published periodically, 17. his *Lettres à ses Commettans,* Letters to his Constituents, which form, when collected, [illegible] vols, 8vo. It is supposed, that the fatal measure of the junction of the three orders into one national

tional assembly, was greatly promoted by these letters. The public events of these times, and the part taken in them by Mirabeau, are the subject of general history. He lived to see the constitution of 1789 established, but not to see its consequences—the destruction of the monarchy, the death of the king, and the ruin of all property! He was accused, as well as the duke of Orleans, of hiring the mob which attacked Versailles on the 5th and 6th of October 1789; but with him was also acquitted by the tribunal of the Châtelet. The dominion of his eloquence in the National Assembly had long been absolute, and, on the 29th of January 1791, he was elected president. At the latter end of March, in the same year, he was seized by a fever, and died on the 2d of April.

The talents of Mirabeau will not be doubted, though they were certainly rather brilliant than profound. To be noticed, and to lead, were the sole objects of his ambition; and for the attainment of them, he took the side of the discontented, as the best field for his matchless eloquence. Yet there was no man more devoted to the principles of a court than this Marquis, provided he could have a share in the administration; and a share he would have obtained, if any thing moderate would have satisfied him: But he thought nothing worthy of him but a place of active trust, and a high department; stations which all knew him not qualified to fill. Wanting knowledge of great things, he was learned only in the bustling detail of intrigue, and would, at any time, have sacrificed his dearest friend, and the interests of his country, for an opportunity of exercising his brilliant eloquence, and indulging his propensity to satire and lampoon. But the greatest obstacle to his advancement under the old government was the abject worthlessness of his character. Drinking was the only vice in which he did not indulge; and from this he was restrained by his exhausted constitution. To his brother, the Viscount, who was frequently intoxicated, the Marquis one day said, "How can you, brother, so expose yourself?" "What (replied the Viscount)! how insatiable are you? Nature has given you every vice; and having left me only this one, you grudge it me!"

MISTRAL, the name of a wind, which is mentioned in almost every account that we have of Provence, and which is remarkable for blowing almost the whole year from north west or west-north-west, in a climate where the wind should be variable. It is said to contribute to the salubrity of the air, by dispersing the exhalations of the marshes and stagnant waters, so common in the south of Languedoc and Provence; but at times it is also very injurious, or at least very troublesome. It is not, however, on either of these accounts that it is introduced into this Work, but for the sake of the causes assigned by Saussure for its constancy, which may be applied to other winds that nearly resemble it; and which he found might be reduced to three.

"The first and most effectual cause (he says) is the situation of the Gulf of Lyons, the banks of which are the principal theatre of its ravages. This Gulf, in fact, is situated at the bottom of a funnel, formed by the Alps and Pyrenees. All the winds blowing from any point between west and north, are forced by these mountains to unite in the Gulf. Thus, winds which would not have prevailed but at one extremity of the Gulf, or even much beyond it, are obliged to take this route, after having undergone the repercussion of these mountains; and the middle of the Gulf, instead of the calm which it might have enjoyed, is exposed to the united efforts of two streams of wind, descending in different directions. Hence arise those whirlwinds which seem to characterise the mistral, and appear to have induced the ancients to call it *Circius*, *à turbine ejus ac vertigine*. See *Aul. Gellius*, l. ii. cap. 22.

"The second cause is, the general slope of the grounds, descending from all sides towards the Gulf; which becoming all at once lower and more southerly than the lands extending behind it, is, from these joint circumstances, rendered the hottest point of all the adjacent country: and, as the air on the surface of the earth always tends from the colder to the warmer regions, the Gulf of Lyons is actually the centre towards which the air from all colder points between east and west must press. This cause, then, alone would be productive of winds directed to the Gulf, even if the repercussion of the mountains did not exert its influence.

"Finally, it is well known, that in all gulfs the land-winds blow more forcibly than opposite to plains and promontories, whatever be the situation of those gulfs. I apprehend, indeed, on strict examination (says our author), that this cause is blended with the preceding; but as the fact is generally admitted, and in some cases can be explained only by reasons drawn from the effects of heat, it may not improperly, perhaps, be distinctly mentioned. It is, at least, necessary to suppose, that several causes produce the mistral, in order to understand why, notwithstanding the variableness of the seasons and temperatures, that wind is so singularly constant in Lower Languedoc and Lower Provence. A very remarkable instance of this constancy is recorded by the Abbé Papon, in his *Voyage de Provence*, tome ii. p. 81. He asserts, that during the years 1769 and 1770, the mistral continued for fourteen months successively. But the three causes which I have stated, taken separately, will explain its frequency, and, united, will account for its force."

MIXT ANGLE, or *Figure*, is one contained by both right and curved lines.

Mixt Number, is one that is partly an integer and partly a fraction; as $3\frac{1}{4}$.

Mixt Ratio, or *Proportion*, is when the sum of the antecedent and consequent is compared with the difference of the antecedent and consequent;

$$\text{as if} \begin{cases} 4:3::12:9 \\ a:b::c:d \end{cases}$$

$$\text{then} \begin{cases} 7 \ : \ 1 \ :: \ 21 \ : \ 3 \\ a+b:a-b::c+d:c-d. \end{cases}$$

MOCASSIMAH, in Bengal, revenue settled by a division of the produce.

MOCHULKAH, bond or obligation.

MŒRIS, a lake in EGYPT, occasionally mentioned in that article (*Encycl.*), and generally supposed the production of human art. Of this, however, Mr Brown says it bears no mark "The shape, as far as was distinguishable, seems not inaccurately laid down in D'Anville's map, unless it be, that the end nearest the Nile should run more in a north west and south-east direction. The length may probably be between 30 and 40 miles; the breadth, at the widest part he could gain, was 5000 toises, as taken with a sextant; that is, near-

ly six miles. The utmost possible extent of circuit must of course be 30 leagues. On the north-east and south is a rocky ridge, in every appearance primeval. In short, nothing can present an appearance more unlike the works of men. Several fishermen, in miserable boats, are constantly employed on the lake. The water is brackish, like most bodies of water under the same circumstances. It is, in the language of the country, *Birket el-kerun*, probably from its extremities bearing some resemblance to horns.

MOFUSSEL, a relative term, signifying the subordinate lands or districts, opposed to Sudder, which is the head.

MOHACZ, Mohatz, or *Mohqz*, a town in the Lower Hungary, upon the Danube, between the river Sarwiza to the north, and the Drave to the south; four German miles from either, six from Esseck to the north, and nine from Colocoa to the south. This otherwise small place is memorable for two great battles here fought; the first between Lewis king of Hungary and Solyman the Magnificent, in 1526: in which that unfortunate Prince Lewis (being about 20 years old), with 25,000 men, fought 300,000 Turks; when, being overpowered by numbers, 22,000 of the Christian army were slain upon the place; 5000 waggons, eighty great cannon, 600 small ones, with all their tents and baggage, were taken by the victors; and the King, in his flight over the brook Curass, fell into a quagmire, and was swallowed up. After which, Solyman took and slew 200,000 Hungarians, and got such a footing in that kingdom, that he could never be expelled. This fatal battle was fought October 29. The second, in some part, retrieves the loss and infamy of the former. The Duke of Loraine being sent by the Emperor, with express orders to pass the Drave and take Esseck, his highness, July 10, 1687, with great difficulty passed that river, then extremely swelled with rains; but finding the Prime Visier encamped at Esseck, with an army of 100,000 men, so strongly, that it was not possible to attack him in that post without the ruin of the Christian army, he retreated, and repassed it the 23d of the same month; where, upon the 29th, the Prime Visier passed that river at Esseck; and upon August 12th, there followed a bloody fight, in which the Turks lost 100 pieces of cannon, 12 mortars, all their ammunition, provisions, tents, baggage, and treasure, and about 8000 men upon the place of battle, besides what were drowned in passing the river, which could never be known. After which victory, General Dunewalt, September 30th, found Esseck totally deserted by the Turks, and took possession of it.

MOHER, in Bengal, a gold coin, worth about 33 shillings.

MOHERIR, a writer of accounts.

MOINEAU, a flat bastion raised before a curtin when it is too long, and the bastions of the angles too remote to be able to defend one another. Sometimes the moineau is joined to the curtin, and sometimes it is divided from it by a moat. Here musquetry are placed to fire each way.

MOLE (See Talpa, *Encycl.*), is an animal exceedingly troublesome, both to gardeners and farmers; and there are persons who contrive to make a livelihood by the trade of *mole-catching*. These men, it is well known, are generally quacks and cheats; and the secrets which they sell for extirpating those destructive animals are of very little avail. Even poison seldom produces any considerable effect; because the mole, while it does not drink, lives only on roots and worms. Under the word Mole (*Encycl.*), some directions will be found for clearing fields of this destructive animal; but the following are perhaps preferable, as they seem to have been the result of much experience: Mole.

Immediately at day break, it will be necessary to make a tour round the garden or meadow, from which it is wished to extirpate the moles; for at that time they will be all found at work, as may be seen by the hills newly thrown up. If the person is then close to the hill, he must proceed as the gardeners do, and turn up with a stroke of the spade the hill together with the digger. The passage is then cut through before the animal is aware of the attack; and therefore it has not power to escape. If the mole-hill be fresh, even though the animal may not be throwing up earth, the person ought not to lose his time in waiting, but should immediately proceed to the operation above mentioned.

If you find a fresh hill standing by itself, which seems to shew by its situation that it has no communication with any other, which is always the case when the mole has worked from the surface downwards in endeavouring to procure a more convenient habitation, after the hill has been turned up with the spade, a bucket of water should be poured over the mouth of the passage. By these means the animal, which is at no great distance, will be obliged to come forth, and may be [illegible] caught with the hand.

You may discover also whether a hill has any communication with another, if you apply your ear to it, and then cough or make a loud noise. If it has no communication with the neighbouring hills, you will hear the terrified animal make a noise by its motion. It will then be impossible for it to escape; and you may either pour water into the hole, or turn up the hill with a spade, until the mole is found; for, in general, it never goes deeper into the earth than from fifteen to eighteen inches.

When any of the beds in a garden have been newly watered, the mole, attracted by the coolness and moisture, readily repairs thither, and takes up its residence in them, making a passage at the depth of scarcely an inch below the surface. In that case it may easily be caught. When you see it at work, you need only tread behind the animal with your feet on the passage to prevent its retreat, and then turn up the hill with a spade; by which means you will be sure to catch it.

When you dig after it with a spade, the animal forces its way downwards into the earth in a perpendicular direction, in order that it may the better escape the threatened danger. In that case it will not be necessary to dig long, but to pour water over the place, which will soon make the animal return upwards.

People, in general, are not aware of the great mischief occasioned in fields and gardens by these animals. We are, however, informed by Buffon, that in the year 1740 he planted fifteen or sixteen acres of land with acorns, and that the greater part of them were in a little time carried away by the moles to their subterranean retreats. In many of these there were found half a bushel, and in others a bushel. Buffon, after this circumstance, caused a great number of iron traps to be

Moments, Mongearts. constructed; by which, in less than three weeks, he [illegible] 1300. To this instance of the devastation occasioned by these animals, we may add the following: In the year 1742 they were so numerous in some parts of Holland, that one farmer alone caught between five and six thousand of them. The destruction occasioned by these animals is, however, no new phenomenon. We are informed by history, that the inhabitants of the island of Tenedos, the Trojans, and the Æolians, were infested by them in the earliest ages. For this reason a temple was erected to Apollo Smynthius, the destroyer of moles. See *Oeconomische Hefte*, Vol. VII. Part 5. and Vol IX. Part 4; or *Phil. Magazine*, N° 5.

MOMENTS, in the new doctrine of infinites, denote the indefinitely small parts of quantity; or they are the same with what are otherwise called infinitesimals and differences, or increments and decrements: being the momentary increments or decrements of quantity considered as in a continual flux.

Moments are the generative principles of magnitude; they have no determined magnitude of their own, but are only inceptive of magnitude.

Hence, as it is the same thing if, instead of these moments, the velocities of their increases and decreases be made use of, or the finite quantities that are proportional to such velocities; the method of proceeding which considers the motions, changes, or fluxions of quantities, is denominated by Sir Isaac Newton, the *method of fluxions*.

Leibnitz, and most foreigners, considering these infinitely small parts, or infinitesimals, as the differences of two quantities, and thence endeavouring to find the differences of quantities, *i. e.* some moments, or quantities indefinitely small, which taken an infinite number of times shall equal given quantities, call these moments differences; and the method of procedure, the differential calculus.

MONGEARTS, one of the tribes of wandering Arabs which inhabit the SAHARA, or Great Desert of Africa. Their time is wholly occupied by tending their cattle; and because they are little skilled in the use of arms, *Mongeart* is a term of contempt among the people by whom they are surrounded. Their country, with its produce, will be described under the title SAHARA in this *Supplement*; it is the business of this article merely to exhibit the manners of the people.

They are all Mahometans, and offer up prayers three times a day, sometimes oftener; but having no mosques, these prayers are never pronounced in public, except when the horde is visited by a priest, who seldom comes but upon account of the childrens education. Then all the Arabs assemble at the hour of prayer, place themselves in a line, turn to the east, and, wanting water in the desert, rub their face and arms with sand; while the priest recites aloud the general prayer. It is the same as that which is rehearsed by the public crier in the mosques in civilized countries.

The priests are employed in travelling about the country to instruct the children. There is nothing like force in their education. The little boys meet in the morning of their own accord, at the place of instruction, which is to them a place of recreation. They go there with a small board inscribed with the Arabic characters, and a few maxims of the Koran. The oldest, and the best informed, receive their lessons directly from the priests, and afterwards communicate them to their fellows. They are never corrected; because it would be a crime to beat a child, who, according to the received notions, has not sufficient reason to distinguish good from evil. This lenity extends even to the children of Christians, though in a state of slavery. They are treated in all respects like the children of Arabs; and the man who should be rash enough to strike one of them, would endanger his life. Very different is their treatment of Negro children; who may indeed join in all the amusements of the young Arabs, and even attend the public schools; but if they be guilty of a fault, they are severely punished.

When the child of a Mongeart becomes tired of the places of public instruction, he quits them at pleasure, and, without feeling constraint, or hearing reproach, goes and employs himself in tending his father's flocks: and accordingly there are very few among them who can read. Those who persevere in the study of the Koran are made priests, after having past an examination before the learned elders, and enjoy the greatest public consideration. They have no need of cattle; for those of the nation being theirs, they find their subsistence everywhere.

It is generally at seven or eight years of age that children undergo the painful operation of circumcision. Their head is also shaved, nothing being left but four locks of hair; one of which is cut off in a meeting of the family, at each remarkable action performed by the child. If, at the age of 12 or 13, he kill a wild boar, or other beast of prey, that should fall upon his flock, he loses one of his locks. If, in the passage of a river, a camel be carried away by the stream, and he save it by swimming to its assistance, another is cut off. If he kill a lion, a tiger, or a warrior of an hostile nation, in a surprise or an attack, he is considered as a man, and his head is entirely shaved.

Different from the other Arabs their neighbours, and indeed from the Mahometans in general, the Mongearts trouble no man on account of his religion. The only one which they do not tolerate is the Jewish; and were a Jew to enter their territory, and have the misfortune to be taken, he would certainly be burnt alive.

According to M. Saugnier, the women are much more respected among the Mongearts than among the neighbouring nations; but the evidences which he gives of that respect are very extraordinary.

When a Mongeart is desirous of undertaking the care of a family, he pitches upon the girl that pleases him the most, and asks her of her father without further formality; nor can the latter refuse her, unless the man who pretends to her hand have done something contrary to the laws of the nation. The girl is conducted by her parents to the tent of her future husband, where there is always an abundant repast prepared for the ceremony. Presents are made to the father; but if the son in law be poor, his wife's family assist him, and furnish him with the means of increasing his flocks; if, on the contrary, he be rich, and the father poor, he supports the whole family in his own tent. The employment of the wife, thus married, is to prepare the food; to spin the goats and camels hair, of which the tents are made; to milk the cattle; to pick up the necessary supply of wood for the night; and when the hour of repast is come, to wait upon her husband. She

then

Mongeart. then eats by herself what has been left by him and his male slaves. She is, indeed, in no great danger of having a rival brought into the family; for though polygamy be allowed by his religion, the poverty of the Mongeart generally prevents him from taking a plurality of wives. She is, however, liable to be divorced at will when she does not bear boys; but if she have the good fortune to have one or more male children, her husband's regard for her is inconceivable. She has no longer a divorce to fear, has an absolute authority in the tent, and passes her whole time in conversation, sleep, or dancing, as she thinks fit. The captive negresses do all her work, and are no longer assisted in their labour by the Arab's wife, who treats them, on the contrary, with the greatest harshness and arrogance.

When a woman is not agreeable to her husband, or when he is disagreeable to her, they have it in their power to part. The formality in this case consists in the wife's retiring to her parents. If the husband be attached to her, he goes thither in quest of her; but if she persist in refusing to return, she is free, and at liberty to marry another. If, however, she have had a child, especially a boy, she has not the same privilege; in that case, if her retreat should last more than eight days, it might be punished with death.

When a man beats his wife, it is a sure sign that he is sincerely attached to her, and that he does not mean to part with her; if he content himself with reproaches, the wife thinks herself despised, and infallibly retires to her parents. Hence it is, that in the most trifling disputes the women are cruelly beaten: they prefer it to the complaints that the husband might make to their parents; this proof being the most certain one of a man's fondness for his wife. When a girl marries, she makes up her mind to such treatment, deeming it much more supportable than the humiliations she would otherwise experience from her family, in consequence of her husband's complaints.

The conjugal fidelity of the Mongeart women is incorruptible. Differing in their opinions from many other Mahometans, they believe themselves immortal like the men; but they do not flatter themselves with the possibility of happiness in the other world, unless they shall have been faithful to their husbands in this. Women, who have been false to their husband's bed, will be doomed, they think, to eternal slavery to the more virtuous part of their sex, without ever partaking, in the smallest degree, of their bliss.

Mongeart women often visit one another; and on these occasions, the honour consists in letting the female who comes to see her friend or relation do all the work of the tent. The visitor assumes the management of every thing, dresses the victuals, churns the butter, and keeps herself continually employed; while her friend entertains her with an account of the different affairs of the family or nation. The heartiness of the welcome is measured by the extent of the work submitted to the guest, who generally prepares double the usual quantity of food; so that the Arab is obliged to invite his neighbours to partake of the repast. The slaves are always pleased with these entertainments, a larger portion then coming to their lot. It is the business of the visitor to do the honours; nor will she suffer any body about her to remain dissatisfied.

The laws of hospitality are observed among the Mongearts as among all the wandering Arabs. Indeed they are carried to such a length, that were a man to enter the tent of him whom he had wounded, or even killed, he would there meet with a sacred and inviolable asylum, although surrounded by those who must naturally desire his ruin. The tent of the chief is always that to which strangers, upon their arrival in the horde, are directed. But the chief could not entertain, at his own expence, all the strangers that happen to pass; and therefore every tent in the horde is obliged to furnish him with two pounds of ground barley *per* week, to enable him to maintain the ancient hospitality.

The chiefs of hordes are always the eldest of their families. The difference of wealth is not considered; the chief often having several individuals at his horde richer than himself, who nevertheless obey him in every particular. He is, properly speaking, their king; examines their difference with the old men, and judges without appeal. As to himself, he cannot be tried but by the chiefs of several hordes assembled. It is his business to determine the spots where the tents are to be pitched, the moment of departure, and the place where the caravan is to stop. If the pasturage do not suffice for the herds of all the horde, it divides, and the chief assigns the ground for the different encampments. They are very often composed of no more than seven or eight tents, according to the quality of the ground they meet with. The tent of the chief is always the largest and most lofty, and is placed in the centre of the divisions. When it is determined upon to quit an encampment, which never happens till the pasture is exhausted, the chief sets off to choose another spot. In these removals the women alone do all the work. Early in the morning they fold up the tent, and load every thing upon the camels backs; they then move slowly on, that the cattle may have time to feed upon the way.

Great respect is paid by the Mongearts to all old men, who enjoy the same prerogatives as the priests, and such Arabs as have visited the tomb of Mahomet at Mecca. Together with the chief they are the judges of the horde, and take cognizance of all offences, the pain of death being the only punishment which they cannot decree. An assembly of several chiefs is the only tribunal which can inflict capital punishment; but as the accused has generally a number of friends, it seldom happens that he is capitally convicted.

A war between two Mongeart tribes seldom happens, and is never bloody; but the different families destroy one another fast enough in their intestine broils. They are all thieves; and indeed theft is a crime only in the day-time, being authorised by law during the night, in order to compel them to take care of their cattle. Could they find redress when robbed by night, they would be less vigilant; and their herds and flocks would be more exposed to the wild beasts that over run their country; but being obliged to be on their guard even against their nearest neighbours, they are always ready to repel both the lion and the tiger. Theft, even in the day-time, is so far from being punished, unless detected at the instant of commission, that when any thing is stolen unperceived, it becomes the lawful property of the thief. In vain would the rightful owner recognize it in his neighbour's tent, he cannot reclaim it; it ceases to be his from the moment he has been negligent in its care. Hence arises this peoples inclination for rapine:

Mongearts they do not think they commit a crime, and only follow, in this regard, a custom allowed by their laws.

When an Arab is going to market, or on his return from thence, if he do not take the greatest care to keep his journey a secret, he is often attacked. Neighbouring Arabs are desirous of profiting by his industry; and as there are no persons in the country appointed to apprehend robbers, the hope of booty spurs them on to the attack. That they may have nothing to fear, they lie in wait, when the night is coming on, for him whom they mean to pillage. Their intention is never to kill; they only endeavour to surprize, to disarm, and to make themselves masters of every thing that comes in their way. But it sometimes happens, that the man they intend to plunder, being acquainted with the customs of his country, keeps an attentive ear, stands on his guard, fires upon his assailants at the first motion he observe and then fights desperately with his dagger. The report of the musket almost always brings out the neighbouring Arabs, who, in virtue of the laws of hospitality, take the defence of the weaker side. They run up well armed; and then woe to the aggressors, if they do not save themselves by a speedy flight.

The flocks and herds of the Mongearts are composed of nothing but sheep, goats, and camels; all animals patient of thirst. Horses are very scarce in these cantons, none but the possessors of numerous herds being able to keep them; because, for want of water, it is necessary to have milk in sufficient abundance to give it them to drink. Great care is taken to preserve the camel's urine, both to mix with milk, and to wash the different vessels in which they put their food. Detestable as is this mixture of milk and urine, they are often reduced to the use of it; hunger and thirst give a relish to every thing.

The only workmen useful to this nation are blacksmiths or goldsmiths, as they may be called indifferently. The Mongearts not being sufficiently laborious to apply themselves to such occupations, these workmen come from Bilidulgerid, and disperse themselves all over the different parts of the desert. Wherever there are tents they are sure to find work. They are fed for nothing, and receive besides the hire for their labour. They make trinkets for the women, such as ear-rings and bracelets, &c. mend the broken vessels, by rivetting them, and clean the arms. They are generally paid in skins, goats and camels hair, or ostrich feathers, according to their agreement. Those who have silver pay them a tenth part of its weight for any thing wrought out of that metal. On their return they sell what they have earned; four or five excursions at most enabling them to live afterwards at their ease in their own country.

The Mongearts always carry a leathern bag, suspended from their neck, in which they put their tinder, their pipe, and their tobacco. Their daggers are elegant; the hilt is always black, and inlaid with ivory; the blade is crooked, and sharp on either side; the sheath is of brass on one side, and of silver on the other, and of very tolerable workmanship. They wear sabres when they can get them, and prefer those of Spanish make. Their muskets are always highly ornamented; the stock is very small, and inlaid on every side with ivory, and the barrel embossed with brass or silver, according to the opulence of the owner. There is a spring to the lock, covering the priming, to prevent the piece from going off, contrary to the intention of him who carries it. The poor, who do not possess muskets, wear daggers, made like the Flemish knives, with leathern sheaths. They arm themselves also with a thick stick, to the end of which they fix a kind of iron wedge. This weapon is exceedingly dangerous at close quarters. Others carry *zagays*, or slender javelins. In a word, the principal riches of an Arab, and his highest gratifications, are a handsome musket and a good dagger. He prefers them to neatness of apparel; for as to dress, it is indifferent to him whether he be clothed in Guinea blues, woollen stuffs, or goats skins. Their arms being their principal ornament, they take particular care to put the muskets in leathern bags, by way of keeping them in good order, and preserving them from the rust.

Mongearts All the riches of the Mongearts consist in their herds; and accordingly they take the greatest care to preserve them. If a beast be sick, every thing is done to cure it; no care is spared; it is even treated with more attention than a man: but when it evidently appears that there is no hope of saving its life, they kill and eat it. If it be a camel, the neighbours are called in to partake of the repast; if a goat, the inhabitants of the tent suffice for its consumption. An animal that dies without shedding blood is unclean. Its throat must be cut; the person who kills it turning to the east, and pronouncing beforehand the first words of the general prayer. An animal killed by a wild boar is unclean; nor is it eaten although its blood has been shed, because the wild boar is itself an unclean beast. That species is so numerous in the desart, that they do more mischief than all the other wild beasts together. The Arabs kill as many as they can; but never taste their flesh.

Whatever losses an Arab may meet with, he is never heard to complain; he rises superior to poverty, supports hunger, thirst, and fatigue, with patience, and his courage is proof against every event. God will have it so, says he: he employs, however, every means in his power to avert misfortune; and often exposes himself to the greatest dangers to procure matters of no real utility.

When a father of a family dies, all the effects in his tent are seized upon by the eldest son present at his decease. Gold, silver, trinkets, every thing disappears; and the absent children have only an equal share in the division of the cattle and the slaves. The girls are entirely excluded from all participation, and take up their residence with their eldest brother. If the deceased leave children in helpless infancy, the mother takes them with her to her sister's, if she have a sister married; if not, to her own maternal roof. The dead man's possessions, however, are not lost; the chief of the horde takes care of them, and delivers them in equal portions to the heirs, as soon as they are old enough to manage their own property. If an Arab die without male children, his wife returns to her relations, and his brother inherits his effects.

The Mongearts have a rooted abhorrence of the Spaniards, and never fail to massacre every man of that nation who is so unfortunate as to be shipwrecked on their coasts, while they reserve the women for sale at Morocco. The reason of this hatred is, that the inhabitants of the Canaries make frequent descents on the Mongeart coasts, and carry off men, women, cattle, and

every thing that they meet with ; and these people, being ignorant of the fate of their countrymen, retaliate by death on all Spaniards that fall into their hands, whilst they treat the British and French as well as they can.

MONNIER (Peter Charles Le), was born at Paris on the 20th of November 1715. The profession of his father, or the rank which he held in society, we have not learned ; and we are equally ignorant of the mode in which he educated his son. All that we know is, that young Monnier, from his earliest years, devoted himself to the study of astronomy ; and that, when only sixteen years of age, he made his first observation, viz. of the opposition of Saturn. At the age of twenty he was nominated a member of the Royal Academy of Sciences at Paris. In the year 1735 he accompanied Maupertuis in the celebrated expedition to Lapland, to measure a degree of latitude. In 1748 he went to Scotland with Lord Macclesfield, to observe the annular eclipse of the sun, which was most visible in that country ; and he was the first astronomer who had the pleasure to measure the diameter of the moon on the disk of the sun.

Louis XV. it is well known, was extremely fond of astronomy, and greatly honoured its professors : he loved and esteemed Le Monnier. I have seen the king himself (says Lalande) come out of his cabinet, and look around for Le Monnier ; and when his younger brother was presented to him on his appointment to the office of first physician, his Majesty was pleased to wish him the merit and reputation of his brother the astronomer. All the remarkable celestial phenomena were always observed by the king, in company with Le Monnier. Thus he observed with him, at his chateau of St Hubert, the two celebrated transits of Venus thro' the disk of the sun in the years 1761 and 1769; as appears from the Memoirs of the Royal Parisian Academy of Sciences. It well deserves to be here recorded in what manner the king behaved during these important observations, and how little he disturbed his astronomers (the celebrated La Condamine being likewise permitted to observe the transit in his presence) in this occupation ; the proper time for which, if permitted to pass by, could not be recalled. Le Monnier relates in his Dissertation, that "his Majesty perceiving that we judged the last contacts to be of the greatest importance, a profound silence at that moment reigned around us." At the transit of Venus in 1769, the king allowed the Marquis de Chabert, an intelligent and expert naval officer, who was just returned from a literary voyage to the Levant, to assist at the observation. In a court like that of Louis XV. so scrupulously observant of etiquette, these will be allowed to have been most distinguished marks of honour, and of royal favour and condescension.

In the year 1750, Le Monnier was ordered to draw a meridian at the royal Chateau of Bellevue, where the king frequently made observations. The monarch on this occasion rewarded him with a present of 15,000 livres ; but Le Monnier applied this sum of money likewise in a manner that redounded to the honour of his munificent sovereign and of his country, by procuring new and accurate instruments, with which he afterwards made his best and most remarkable observations. In 1742, the king gave him in Paris *Reu de la Poste*, a beautiful free dwelling, where, till the breaking out of the revolution, he resided, and pursued his astronomical labours, and where his instruments in part yet remain. Some of them the present French government has, at the instance of Lalande, purchased for the National Observatory. In 1751, the king presented him with a block of marble eight feet in height, six feet in breadth, and fifteen inches in thickness, to be used for fixing his mural quadrant of five feet. This marble wall, together with the instruments appended to it, turns on a large brass bell and socket, by which the quadrant may be directed from south to north : thus serving to rectify the large mural quadrant of eight feet, which is immoveably made fast to a wall towards the south.

With these quadrants Le Monnier observed, for the long period of forty years, the moon with unwearied perseverance at all hours of the night. It is requisite, to be a diligent astronomer, to be able to conceive to what numberless inconveniences the philosopher is exposed during an uninterrupted series of lunar observations. As the moon during a revolution may pass through the meridian at all hours of the day or night the astronomer who, day after day, prosecutes such observations, must be prepared at all, even the most inconvenient, hours, and sacrifice to them his sleep and all his enjoyments. How secluded from all the pleasures of social intercourse, and how fatiguing such a mode of life is, those astronomers, indeed, know not who then only set their pendulum clocks in motion, when some of the eclipses of the sun, moon, or of the satellites of Jupiter, are to be viewed. At this time, and in the present state of the science, these are just the most insignificant observations; and an able astronomer, well supplied with accurate instruments, may *every day*, if he take into his view the whole of his profession, make more important and more necessary observations

Le Monnier was Lalande's preceptor, and worthy of such a scholar ; and he promoted his studies by his advice, and by every other means in his power. Le Monnier's penetrating mind, indeed, presaged in young Lalande, then only sixteen years old, what in the sequel has been so splendidly confirmed. In his twentieth year, he became, on the recommendation of his preceptor, a member of the Royal Academy : and in 1752 he was proposed by him as the fittest person to be sent to Berlin, to make with La Caille's, who had been sent to the Cape of Good Hope, correspondent observations, for the purpose of determining the parallaxes of the moon, then but imperfectly known. Le Monnier lent his pupil for this expedition his mural quadrant of five feet. His zeal for astronomy knew no bounds. For this reason Lalande, in his *Notice des Travaux du C. Le Monnier*, says of himself : "*Je suis moi-meme le principal resultat de son zele pour l'astronomie.*"

Le Monnier was naturally of a very irritable temper : as ardently as he loved his friends, as easily could he be offended ; and his hatred was then implacable. Lalande, as he himself expresses it, had the misfortune to incur the displeasure of his beloved preceptor ; and he never after could regain his favour. But Lalande's gratitude and respect for him always continued undiminished, and were on every occasion with unremitting constancy publicly declared : patiently he endured from him undeserved ill treatment ; so much did he love and

esteem

Mon

efteem his inftructor and mafter to the day of his death. "I have not ceafed to exclaim (write. Lalande), as Diogenes exclaimed to his mafter Antifthenes, You cannot find a ftick ftrong enough to drive me away from you!"

What a noble trait in the character of Lalande, who in 1707 wrote likewife an eulogium on Le Monnier in the ftyle of a grateful pupil. penetrated with fentiments of profound veneration and efteem for his beloved mafter; but Le Monnier would not read it. This is not the place to give a circumftantial account of this intricate quarrel; we fhall only further remark, that Lalande was the warm friend and admirer of the no lefs eminent aftronomer La Caille, whom Le Monnier mortally hated. An intimate friendfhip likewife fubfifted between Le Monnier and D'Alembert; but Lalande had no friendly intercourfe with the latter.

Among the fcholars of Le Monnier may likewife be reckoned Henwart, the celebrated geometrician and profeffor of mathematics at Utrecht; who, in a letter to Von Zach, aftronomer to the Duke of Saxe Gotha, dated the 26th of May 1797, fays, "Le Monnier is a penetrating and philofophical aftronomer: I learned much from him in Paris; though I lodged with the late De l'Ifle, where I frequently made obfervations in company with Meffier. Le Monnier was the friend of D'Alembert; and confequently an oppofer of Lalande"

This great man, who had, for fome years, ceafed to exift either for the fcience of aftronomy, or for the comfort of his friends, died at Lizeaux, in the province of Normandy, in 1799, aged 84 years. He left behind him fome valuable manufcripts, and a number of good obfervations; with refpect to which he had always been very whimfical, and of which in his latter years he never would publifh any thing. He had by him a feries of lunar obfervations, and a multitude of obfervations of the ftars, for a catalogue of the ftars, which he had announced fo early as the year 1741; among which was twice to be found the new planet Uranus: (See *Lalande's Aftronomie, Tables*, p. 188, (A). The more he was requefted to communicate his obfervations, the more obftinate he became; he even threatened to deftroy them. At the breaking out of the revolution, Lalande was greatly alarmed for the fafety of thefe papers; he wifhed to preferve them from deftruction, and made an attempt to get them into his poffeffion; but all his endeavours were in vain. He was only able to learn, that Le Monnier had hidden them under the roof of his houfe. Le Monnier having been firft feized with a fit of the apoplexy fo early as the 10th of November 1791, Lalande apprehended, left, if no one except himfelf fhould know where he had hidden his papers, the infirm old man might perhaps have himfelf forgot it. He hopes, however, that La Grange, who married his fecond daughter, may have fome information concerning them. Le Monnier left behind him no fon.

Monomial, Monfelemines.

MONOMIAL, in algebra, is a fimple or fingle nomial, confifting of only one term; as a or $a x$, or $a^2 b x^2$, &c.

MONOTRIGLYPH, a term in architecture, denoting the fpace of one triglyph between two pilafters, or two columns.

MONSELEMINES, are a people which inhabit that part of BILEDULGERID (fee *Encycl.*) that borders on the territories of the Emperor of Morocco. They are a mixed race, being defcended from the ancient Arabs and fugitive Moors; and they occupy a fpace of land. of which the limits are indicated by lofty columns placed at intervals towards the defart. Their territory extends from about 30 leagues beyond Cape Non, to the diftance of 20 leagues from St Croix or Agader. Though of different qualities, it is, for the moft part, very fertile, and produces the neceffaries of life with little cultivation. The plains are watered by an infinite number of ftreams, and abound with palm, date, fig, and almond trees. The gardens produce excellent grapes, which are dried by the Arabs, and converted into brandy by the Jews. Great quantities of oil, wax, and tobacco, appear in the public markets.

More induftrious and more laborious than their neighbours, the Monfelemine nation cultivates the earth. The chiefs of families choofe the ground moft fit for cultivation. Its furface is turned flightly over with a kind of hoe, and then the feed is fown upon it: the field is furrounded with bufhes, to mark the fpot, and to preferve it from the cattle of the wandering Arabs. When the crop is ripe, which is generally at the end of Auguft, three months after the fowing of the feed, it is cut about fix inches from the ear, and formed into little bundles; during which time every one labours without intermiffion from morning to night. The corn is brought before the tent, thrafhed, winnowed, and placed in the magazines. When the harveft is over, they fet fire to the long ftubble, and abandon the field for two or three years. Their magazines are large holes in the earth, formed like the fruftum of a cone, the infides of which are hardened by burning wood in them, before the half winnowed corn be depofited. When filled with corn, they are covered with planks placed clofe to each other; over which a layer of earth is laid level with the foil, to prevent it from being difcovered by enemies. In thefe magazines every one fhares in proportion to the number of men he employed in the common labour.

The inhabitants of the plains remain by the cultivated fields in feed time, and return at the time of harveft. During the intervals they wander in all directions with their cattle, taking only neceffaries along with them, and having recourfe to the magazines when they require

(A) Such is the French and German account of his difcovery of this planet; but our readers have been very inattentive, if they have not perceived, in various articles of this Work, complete proofs of the plagiarifm of our neighbours on the Continent, from the celebrated philofophers and divines of England. As it is extremely probable that, half a century hence, a claim may be put in for Le Monnier's difcovery of the Georgium Sidus (*Uranus*), fimilar to that which in 1757 the editor of Abbe St Real's works put in for that Abbé being the author of Leflie's *Short Method with the Deifts* (fee LESLEY in this *Suppl.*), we think it our duty to declare, that in 1800 there was no evidence whatever on which to found that claim, and that the difcovery was then univerfally allowed to have been made by Herfchel.

Monfele mines.

quire a fupply. The more opulent people, and the artizans who are engaged in fedentary occupations, dwell in towns, which are all fituated upon the declivity of hills. Their houfes are built of ftone and earth according to the Moorifh conftruction, low and covered with floping terraces; yet they are fo much injured by the heavy rains which prevail for three months of the year, as to be rendered uninhabitable in 15 or 20 years. Thofe who refide in towns are generally weavers, fhoemakers, goldfmiths, potters, &c and have no cattle; but the more opulent perfons have flocks and herds of cows, horfes, camels, fheep, goats, befides poultry, which are kept by their flaves at a diftance from the towns. In the towns they take two meals a day; one at ten o'clock, and the other at the fetting of the fun, though the inhabitants of the country only eat in the evening. In the towns they fleep in mats upon the floors of their apartments, and make ufe of linen; but the inhabitants of the country fleep upon terraces in the open air. The paftoral families of the country practife hofpitality like thofe of the defart, and make the traveller pay nothing for his entertainment. In the towns this practice is impoffible, as the concourfe of ftrangers, efpecially on market-days, would foon impoverifh the inhabitants. In this manner hofpitality is always extinguifhed among a trading and commercial people. It is only where the fuperfluity of commodities runs neceffarily to wafte, that it is ever practifed in a great extent; but where every commodity can find a market, every kind of property acquires a definite value, and will be preferved with the fame care as money.

By M. Saugnier the government of the Monfelemines is faid to be republican; but he writes inconfiftently about it In one place, he fays that they choofe their chiefs annually; in another, that in the time of war they choofe from the natives or fugitive Moors indifcriminately, chiefs, whofe authority lafts no longer than the campaign, during which it is abfolute; and he afterwards reprefents their goverment as a kind of theocracy, during war as well as peace. But we muft follow him in his detail, as it has been well arranged in a late anonymous publication, entitled, *An Hiftorical Sketch of Difcoveries in Africa*.

At the end of each campaign, he fays the chief gives an account of his actions to the affembled aged men, and is rewarded or punifhed according to his conduct; after which his fucceffor is appointed, and he ferves in the army he commanded as an undiftinguifhed individual. The country is populous, and would be ftill more fo, were it not for the continual wars which its inhabitants are obliged to fupport againft the Emperor of Morocco. The liberty they enjoy imparts energy and courage to their character, and renders their arms invincible to the Moors. They confider it as the moft invaluable poffeffion, and defend it to the laft extremity. The nature of the country, furrounded on every fide by fteep and arid mountains, contributes to fruftrate the efforts of their enemies. The Monfelemine, richer than the fubject of Morocco, is always well clothed and armed. He pays no tribute, enjoys the fruit of his labour and commerce, and, as no contributions are requifite for the charges of the ftate, whatever he acquires is his own. The fugitive Moors are never armed, except when they go to battle; but the natives go continually armed, whether they refide in the country, refort to the markets, attend the affemblies of the nation, or pay vifits.

As the Monfelemine territory is the retreat of the rich Moors, who wifh to fly from the tyranny of the Emperor of Morocco, they are too well acquainted with the Moorifh cuftoms to be furprifed by that prince. No fooner does a Moorifh army take the field, than the inhabitants of the country cantons mount their horfes, and occupy the paffes of the mountains; while the women and flaves, efcorted by a fufficient number of warriors, retire to the interior parts of the country, or, if they be hard preffed, to the defart. Among the paftoral tribes there are many that addict themfelves entirely to arms, and ferve as cavalry in the time of war. During peace they efcort caravans, or exercife themfelves in military evolutions, and the management of their horfes. Being almoft always on horfeback, and wearing no boots, they have a callous lump on that part of the leg that comes in contact with the iron of the ftirrup. Their horfes, which they break in an admirable manner, are the beft in the world: as they are treated with great care by their mafters, they know them, and are obedient to their voice, and will admit no ftranger to mount them.

The Monfelemines derive their origin and name from Mofeilama, a contemporary of Mahomet; and, in their love of liberty, as well as in many of their cuftoms, refemble the Arabs of remoter times. They refpect the prophet like other Mahometans; but neither believe that he was infallible, nor that his defcendants are all infpired by God, nor that their will fhould be a law, nor that fuch faith is neceffary in order to be a good Mahometan. Their priefts are refpected, and in old age generally become the civil judges of the nation; but the influence of the high prieft is almoft defpotic. Though he has no troops, he may command the nation; and war and peace depend upon his will. Though he has no property, every thing is at his difpofal: he requires nothing from any one, and yet all are inclined to give. He adminifters juftice according to the opinion of his counfel, without pretending to be infpired by the prophet.

On Friday the Monfelemines affemble in their mofques to pray: this is likewife the day of their principal market, when their merchandize is expofed to fale in the public fquares, where the old men judge without appeal, when difputes arife. Different from their neighbours of Morocco and Sahara, the Monfelemines never attempt to make profelytes. Their Chriftian flaves are treated with humanity; but they owe this to the avarice of their mafters. Thefe deteft Chriftians, but they love money, and are afraid left ficknefs or death fhould deprive them of the ranfom of the flave, or of the advantage of his labour. Among the inhabitants of the defart, a Chriftian, that adopts the religion of Mahomet, is admitted as a citizen and member of the family, and is prefented with cattle to form an eftablifhment. The Monfelemines pay more attention to the value of their property than the fituation of the infidel. A Chriftian who enters a mofque at Morocco is put to death, or forced to affume the turban. The Monfelemines would turn him civilly out, and content themfelves with impofing the higheft poffible fine. Among the Moors, a Chriftian difcovered in an intrigue with a woman of that nation fuffers death, or fubmits to con-

Monfelemines, Monterey.

conversion; but the Monfelemines prefer money to religion. From them the Christian has nothing to fear: the woman alone is punished, being put into a fack, and thrown into the fea. If a Christian flave among the neighbouring nations defends himfelf againft his mafter, he is punifhed with death; but money faves him among the Monfelemines; he would at moft receive a flight correction.

The Jews are allowed the free exercife of their religion among the Monfelemines, but are treated with the fame indignity as among other Mahometan tribes. A Jew is not permitted to carry arms; and if he fhould make ufe of them againft an Arab, he would be punifhed with death, and probably involve his family in his fate. The Jews inhabit the towns only, where they follow trade and various arts, but are not allowed to cultivate the earth.

Polygamy is permitted, as in other Mahometan countries; but the fituation of the women is more refpectable, and they are not fo much fecluded as among the Moors. They mingle more in fociety, walk at large, and vifit their friends; neither are their apartments fo inviolable. Among the Monfelemines, that degrading picture of humanity is never feen which fometimes occurs in Morocco, a woman drawing the plough with an afs, a mule, or fome other beaft of burden. More happy than the women of the Sahara, and treated with greater attention by their hufbands, they are more humane in their difpofitions. Like other Arab women, they ftain the edges of their eyelids black with henna, and paint their faces red and yellow. Their children are brought up with great care, and are not obliged to exhibit proofs of their courage before they can be confidered as men, as is the cuftom in the defart. Avarice is the principal defect in the character of the Monfelemines. They hoard their money with the utmoft care, bury it in the earth, and in many cafes die without difcovering their fecret even to their children. Mifers, fays M. Saugnier, fhould go to that country, where they would learn means of economy; which would fhew them, that, in comparifon with the Monfelemines, they are themfelves perfect prodigals.

The medicinal applications of the Monfelemines, which differ not from thofe of the MONGEARTS and other inhabitants of the defart, are extremely fimple, but appear fufficiently complex from the mummery of the priefts, who are the depofitories of their medical fcience. Flefh wounds are cauterifed with a hot iron, and then covered with herbs dipped in turtles oil and tar. In headachs, a comprefs is applied with fuch violence that the blood ftarts from the forehead. In internal difeafes, the general remedies are regimen, reft, and a few maxims of the Koran myfterioufly applied to the affected parts.

MONTEREY BAY, in North California, was vifited in 1786 by La Peroufe, who places it in 36° 58′ 43″ N. Lat. and 124° 40′ W. Long from Paris. It is formed by New-year Point to the north, and by that of Cyprus to the fouth; has an opening of eight leagues in this direction, and nearly fix of depth to the eaftward, where the land is fandy and low. The fea breaks there as far as the foot of the fandy downs with which the coaft is furrounded, with a roaring which may be heard more than a league off. The lands north and fouth of this bay are high, and covered with trees. Thofe fhips which are defirous of touching there ought to follow the fouth coaft, and after having doubled the Point of Pines, which ftretches to the northward, they get fight of the prefidency, and may come to an anchor in ten fathoms within it, and a little within the land of this point, which fhelters from the winds from the offing. The Spanifh fhips, which propofe to make a long ftay at Monterey, are accuftomed to bring up within one or two cable's lengths of the land, in fix fathoms, and make faft to an anchor, which they bury in the fand of the beach; they have then nothing to fear from the foutherly winds, which are fometimes very ftrong; but, as they blow from the coaft, do not expofe them to any danger. The two French frigates, which our author commanded, found bottom over the whole bay, and anchored four leagues from the land, in 60 fathoms, foft muddy ground; but there is a very heavy fea, and it is only an anchorage fit for a few hours, in waiting for day, or the clearing up of the fog. At full and change of the moon it is high water at half paft one o clock: the tide rifes feven feet; and as this bay is very open, the current in it is nearly imperceptible. It abounds with whales; a genus of fifhes, of which our *fcientific* voyagers knew fo little, that they were furprifed at their fpouting water!

The coafts of Monterey Bey are almoft continually enveloped in fogs, which caufe great difficulty in the approach to them. But, for this circumftance, there would be few more eafy to land upon; there is not any rock concealed under water that extends a cable's length from the fhore; and if the fog be too thick, there is the refource of coming to an anchor, and there waiting for a clear, which will enable you to get a good fight of the Spanifh fettlement, fituated in the angle formed by the fouth and eaft coaft. The fea was covered with pelicans. Thefe birds, it feems, never go farther than five or fix leagues from the land; and navigators, who fhall hereafter meet with them during a fog, may reft affured that they are within that diftance of it.

A lieutenant-colonel, whofe refidence is at Monterey, is governor of the Californias: the extent of his government is more than 800 leagues in circumference, but his real fubjects confift only of 282 cavalry, whofe duty it is to garrifon five fmall forts, and to furnifh detachments of four or five men to each of the 25 miffions, or parifhes, eftablifhed in old and new California. So fmall are the means which are adequate to the reftraining about 50,000 wandering Indians in this vaft part of America, among whom, nearly 10,000 have embraced Chriftianity. Thefe Indians are, in general, fmall and weak (A), and difcover none of that love of liberty and independence which characterifes the northern nations, of whofe arts and induftry they are alfo deftitute. Their colour very nearly approaches that of the negroes whofe hair is not woolly; the hair of thefe people is ftrong, and of great length; they cut it four or five inches from the roots. Several among them have a beard; others, according to the miffionary fathers, have never had any; and this is a queftion which is even undecided

(A) The chief furgeon of the expedition fays they are *ftrong*, but ftupid.

Mongearts. decided in the country. The governor, who had travelled a great way into the interior of theſe lands, and who had paſſed 15 years of his life among the ſavages, aſſured our author, that thoſe who had no beards had plucked them up with bivalve ſhells, that ſerved them as pincers: the preſident of the miſſions, who had reſided an equal length of time in California, maintained the contrary;—it was difficult, therefore, for travellers to decide between them." The difficulty, ſurely, was not great. By their own account, the governor had travelled much farther into the country than the miſſionary; and his report being confirmed by the evidence of their own ſenſes, was intitled to unlimited credit.

Theſe Indians are extremely ſkilful in drawing the bow; they killed, in the preſence of the French, the ſmalleſt birds: it is true, they diſplay an inexpreſſible patience in approaching them; they conceal themſelves, and, as it were, glide along near to the game, ſeldom ſhooting till within 15 paces. Their induſtry in hunting the larger animals is ſtill more admirable. Perouſe ſaw an Indian, with a ſtag's head fixed upon his own, walk on all fours, as if he were browſing the graſs; and he played this pantomime to ſuch perfection, that all the French hunters would have fired at him at 30 paces, had they not been prevented. In this manner they approach herds of ſtags within a very ſmall diſtance, and kill them with a flight of arrows.

Before the Spaniſh ſettlements, the Indians of California cultivated nothing but maize, and almoſt entirely lived by fiſhing and hunting. There is not any country in the world which more abounds in fiſh and game of every deſcription: hares, rabbits, and ſtags are very common there; ſeals and otters are alſo found there in prodigious numbers; but to the northward, and during the winter, they kill a very great number of bears, foxes, wolves, and wild cats. The thickets and plains abound with ſmall grey tufted partridges, which, like thoſe in Europe, live in ſociety, but in large companies of three or four hundred; they are fat, and extremely well flavoured. The trees ſerve as habitations to the moſt delightful birds; and the ornithologiſts of the voyage ſtuffed a great variety of ſparrows, titmice, ſpeckled wood-peckers, and tropic birds. Among the birds of prey are found the white-headed eagle, the great and ſmall falcon, the goſs hawk, the ſparrow hawk, the black vulture, the large owl, and the raven. On the ponds and ſea-ſhore are ſeen the wild duck, the grey and white pelican with yellow tufts, different ſpecies of gulls, cormorants, curlews, ring-plovers, ſmall ſea water hens, and herons; together with the bee eater, which, according to moſt ornithologiſts, is peculiar to the old continent.

The country about Monterey Bay is inexpreſſibly fertile. The crops of maize, barley, corn, and peaſe, cannot be equalled but by thoſe of Chili; our European cultivators can have no conception of a ſimilar fertility; the medium produce of corn is from ſeventy to eighty for one; the extremes ſixty and a hundred. Fruit trees are ſtill very rare there, but the climate is extremely ſuitable to them: it differs a little from that of the ſouthern French provinces. The foreſt trees are, the ſtone-pine, cyprus, evergreen oak, and occidental plane tree. There is no underwood; and a verdant carpet, over which it is very agreeable to walk, covers the ground. There are alſo vaſt ſavannahs, abounding with all ſorts of game.

Perouſe writes with great reſpect of the wiſe and pious conduct of the Spaniſh miſſionaries at Monterey, who ſo faithfully fulfil the purpoſe of their inſtitution. Totally unlike the monks at CONCEPTION in Chili (ſee that article in this *Suppl*), they have left the lazy life of a cloiſter, to give themſelves up to cares, fatigues, and ſolicitudes of every kind. They invited the of the frigates to dine with them at their monaſtery, contiguous to which ſtands the Indian village, conſiſting of about 50 cabins, which ſerve as dwelling-places to 740 perſons of both ſexes, compriſing their children, which compoſe the miſſion of Saint Charles, or of Monterey. Theſe cabins are the moſt miſerable that are to be met with among any people; they are round, ſix feet in diameter, by four in height; ſome ſtakes, of the ſize of an arm, fixed in the earth, and which approach each other in an arch at the top, compoſe the timber work of it; eight or ten bundles of ſtraw, very ill arranged over theſe ſtakes, defend the inhabitants, well or ill, from the rain and wind; and more than half of this cabin remains open when the weather is fine; their only precaution is to have each of them two or three bundles of ſtraw at hand by way of reſerve.

All the exhortations of the miſſionaries have never been able to procure a change of this general architecture of the two Californias. The Indians ſay, that they like plenty of air; that it is convenient to ſet fire to their houſes when they are devoured in them by too great a quantity of fleas; and that they can build another in leſs than two hours. The independent Indians, who as hunters ſo frequently change their places of abode, have a ſtronger motive.

The monks gave the moſt complete information reſpecting the government of this ſpecies of religious community; for no other name can be given to the legiſlation they have eſtabliſhed. They are ſuperiors both in ſpiritual and temporal affairs: the products of the land are entirely entruſted to their adminiſtration. There are ſeven hours allotted to labour in the day, two hours to prayers, and four or five on Sundays and feſtivals, which are altogether dedicated to reſt and divine worſhip. Corporal puniſhments are inflicted on the Indians of both ſexes who neglect pious exerciſes; and ſeveral ſins, the puniſhment of which in Europe is reſerved only to Divine Juſtice, are puniſhed with chains or the ſtocks.

The Indians, as well as the miſſionaries, riſe with the ſun, and go to prayers and maſs, which laſt an hour; and during this time there is cooked in the middle of the ſquare, in three large kettles, barley meal, the grain of which has been roaſted previous to being ground; this ſpecies of boiled food, which the Indians call *atole*, and of which they are very fond, is ſeaſoned neither with ſalt nor butter, and to us would prove a very inſipid meſs. Every cabin ſends to take the portion for all its inhabitants in a veſſel made of bark: there is not the leaſt confuſion or diſorder; and when the coppers are empty, they diſtribute that which ſticks to the bottom to the children who have beſt retained their leſſons of catechiſm. This meal continues three quarters of an hour, after which they all return to their labours; ſome go to plough the earth with oxen, others to dig the garden; in a word, every one is employed in diffe-

Mongearts. rent domeſtic occupations, and always under the ſuperintendance of one or two of the religious.

The women are charged with little elſe but the care of their houſewifery, their children, and roaſting and grinding the ſeveral grains: this laſt operation is very long and laborious, becauſe they have no other means of doing it but by cruſhing the grain in pieces with a cylinder upon a ſtone. M. de Langle, being a witneſs of this operation, made the miſſionaries a preſent of his mill; and a greater ſervice could not have been rendered them, as by theſe means four women would in a day perform the work of a hundred, and time enough will remain to ſpin the wool of their ſheep, and to manufacture coarſe ſtuffs.

At noon the dinner was announced by the bell; the Indians quitted their work, and ſent to fetch their rations in the ſame veſſels as at breakfaſt: but this ſecond meſs was thicker than the firſt; there was mixed in it corn and maize, and peaſe and beans; the Indians name it *pouſſol*. They return again to their labour from two o'clock till four or five; afterwards they attend evening prayers, which continue near an hour, and are followed by a new ration of *atole* like that at breakfaſt. Theſe three diſtributions are ſufficient for the ſubſiſtence of the far greater number of Indians; and this very economical ſoup might perhaps be very profitably adopted in our years of ſcarcity; ſome ſeaſoning would certainly be neceſſary to be added to it, their whole knowledge of cookery conſiſting in being able to roaſt the grain before it is reduced into meal. As the Indian women have no veſſels of earth or metal for this operation, they perform it in large baſkets made of bark, over a little lighted charcoal; they turn theſe veſſels with ſo much rapidity and addreſs, that they effect the ſwelling and burſting of the grain without burning the baſket, though it is made of very combuſtible materials.

The corn is diſtributed to them every morning; and the ſmalleſt diſhoneſty, when they give it out, is puniſhed by whipping: but it is very ſeldom, indeed, they are expoſed to it. Theſe puniſhments are adjudged by Indian magiſtrates, called *caciques*; there are in every miſſion three of them, choſen by the people from amongſt thoſe whom the miſſionaries have not excluded: but theſe caciques are like the governors of a plantation, paſſive beings, blind executors of the will of their ſuperiors: and their principal functions conſiſt in ſerving as beadles in the church, and their maintaining order and an air of contemplation. The women are never whipped in public, but in an incloſed and ſomewhat diſtant place, leſt perhaps their cries might inſpire too lively a compaſſion, which might ſtimulate the men to revolt; theſe laſt, on the contrary, are expoſed to the view of all their fellow-citizens, that their puniſhment may ſerve as an example. In general they aſk pardon; in which caſe the executioner leſſens the force of his laſhes, but the number of them is never receded from.

The rewards are particular ſmall diſtributions of grain, of which they make little thin cakes, baked on burning coals: and on the great feſtivals the ration is in beef; many of them eat it raw, eſpecially the fat, which they eſteem equal to the beſt butter or cheeſe. They ſkin all animals with the greateſt addreſs; and when they are fat, they make, like the ravens, a croaking of pleaſure, devouring, at the ſame time, the moſt delicate parts with their eyes.

They are frequently permitted to hunt and fiſh on their own account; and on their return they generally make the miſſionaries ſome preſent in game and fiſh; but they always proportion the quantity to what is abſolutely neceſſary for them, always taking care to increaſe it if they hear of any new gueſts who are on a viſit to their ſuperiors. The women rear fowls about their cabins, the eggs of which they give their children. Theſe fowls are the property of the Indians, as well as their clothes, and other little articles of houſehold furniture, and thoſe neceſſary for the chace. There is no inſtance of their having robbed each other, though their faſtenings to the doors conſiſt only of a ſimple bundle of ſtraw, which they place acroſs the entrance when all the inhabitants are abſent.

The men in the miſſions have ſacrificed much more to Chriſtianity than the women; becauſe they were accuſtomed to polygamy, and were even in the cuſtom of eſpouſing all the ſiſters of a family. The women, on the other hand, have acquired the advantage of excluſively receiving the careſſes of one man only. With this, however, it would appear that they are not ſatisfied; for the religious have found it neceſſary to conſtitute themſelves the guardians of female virtue. At an hour after ſupper, they have the care of ſhutting up, under lock and key, all thoſe whoſe huſbands are abſent, as well as the young girls above nine years of age; and during the day they are entruſted to the ſuperintendance of the matrons. So many precautions are ſtill inſufficient; for our voyagers ſaw men in the ſtocks, and women in irons, for having deceived the vigilance of theſe female arguſſes, who had not been ſufficiently ſharp-ſighted.

The converted Indians have preſerved all the ancient uſages which their new religion does not prohibit; the ſame cabins, the ſame games, the ſame dreſſes: that of the richeſt conſiſts of an otter's ſkin cloak, which covers their loins, and deſcends below their groin; the moſt lazy have only a ſimple piece of linen cloth, with which they are furniſhed by the miſſion, for the purpoſe of hiding their nakedneſs; and a ſmall cloak of rabbit's ſkin covers their ſhoulders, which is faſtened with a pack-thread under the chin; the head and the reſt of the body is abſolutely naked; ſome of them, however, have hats of ſtraw, very neatly matted. The womens dreſs is a cloak of deer ſkin, ill tanned; thoſe of the miſſions have a cuſtom of making a ſmall boddice, with ſleeves, of them: it is their only apparel, with a ſmall apron of ruſhes, and a petticoat of ſtag's ſkin, which covers their loins, and deſcends to the middle of the leg. The young girls, under nine years of age, have merely a ſimple girdle; and the children of the other ſex are quite naked.

The independent ſavages are very frequently at war; but the fear of the Spaniards makes them reſpect their miſſions; and this, perhaps, is not one of the leaſt cauſes of the augmentation of the Chriſtian villages. Their arms are the bow, and arrow pointed with a flint very ſkilfully worked: theſe bows are made of wood, and ſtrung with the ſinews of an ox. Our author was aſſured, that they neither eat their priſoners, nor their enemies killed in battle; that, nevertheleſs, when they had

Moors. had vanquiſhed, and put to death on the field of battle, chiefs, or very courageous men, they have eaten ſome pieces of them, leſs as a ſign of hatred or revenge, than as a homage which they paid to their valour, and in the full perſuaſion that this food would be likely to increaſe their own courage. They ſcalp the vanquiſhed as in Canada, and pluck out their eyes; which they have the art of preſerving free from corruption, and which they carefully keep as precious ſigns of their victory. Their cuſtom is to burn their dead, and to depoſit their aſhes in morais.

MOORS, in common language, are the natives of MOROCCO, of whom an account is given under that title in the *Encyclopædia*; but there is another people, a mixed race, called alſo MOORS, who lead a wandering and paſtoral life in the habitable parts of the Great Deſert, and in the countries adjacent to it. Of the origin of theſe Mooriſh tribes, as diſtinguiſhed from the inhabitants of Barbary, nothing farther ſeems to be known than what is related by John Leo the African; whoſe account may be abridged as follows:

Before the Arabian conqueſt, about the middle of the ſeventh century, all the inhabitants of Africa, whether they were deſcended from Numidians, Phœnicians, Carthaginians, Romans, Vandals, or Goths, were comprehended under the general name of *Mauri* or Moors. All theſe nations were converted to the religion of Mahomet, during the Arabian empire under the Kaliphs. About this time many of the Numidian tribes, who led a wandering life in the deſert, and ſupported themſelves upon the produce of their cattle, retired ſouthward acroſs the Great Deſert, to avoid the fury of the Arabians; and by one of thoſe tribes, ſays Leo (that of Zanhaga), were diſcovered, and conquered, the Negro nations on the Niger. By the Niger, is here undoubtedly meant the river of Senegal, which in the Mandingo language is called *Baſing*, or the Black River.

To what extent theſe people are now ſpread over the African continent, it is difficult to aſcertain. There is reaſon to believe, that their dominion ſtretches from weſt to eaſt, in a narrow line or belt, from the mouth of the Senegal (on the northern ſide of that river) to the confines of Abyſſinia. Mr Park deſcribes them as reſembling, in complexion, the Mulattoes of the Weſt Indies, and as having cruelty and low cunning pictured in their countenances. "From the ſtaring wildneſs in their eyes (ſays he), a ſtranger would immediately ſet them down as a nation of lunatics. The treachery and malevolence of their character are manifeſted in their plundering excurſions againſt the Negro villages. Oftentimes, without the ſmalleſt provocation, and ſometimes under the faireſt profeſſions of friendſhip, they will ſuddenly ſeize upon the Negroes cattle, and even on the inhabitants themſelves. The Negroes very ſeldom retaliate. The enterpriſing boldneſs of the Moors, their knowledge of the country, and, above all, the ſuperior fleetneſs of their horſes, make them ſuch formidable enemies, that the petty Negro ſtates, which border upon the deſert, are in continual alarm while the Mooriſh tribes are in the vicinity, and are too much awed to think of reſiſtance.

"Like the roving Arabs, the Moors frequently remove from one place to another, according to the ſeaſon of the year, or the convenience of paſturage. In the month of February, when the heat of the ſun ſcorches up every ſort of vegetation in the deſert, they ſtrike their tents, and approach the Negro country to the ſouth; where they reſide until the rains commence, in the month of July. At this time, having purchaſed corn, and other neceſſaries from the Negroes, in exchange for ſalt, they again depart to the northward, and continue in the deſert until the rains are over, and that part of the country becomes burnt up and barren.

Moor Morinda

"This wandering and reſtleſs way of life, while it inures them to hardſhips, ſtrengthens, at the ſame time, the bonds of their little ſociety, and creates in them an averſion towards ſtrangers, which is almoſt inſurmountable. Cut off from all intercourſe with civilized nations, and boaſting an advantage over the Negroes, by poſſeſſing, though in a very limited degree, the knowledge of letters, they are at once the vaineſt and proudeſt, and perhaps the moſt bigotted, ferocious, and intolerant, of all the nations on the earth; combining in their character the blind ſuperſtition of the Negro, with the ſavage cruelty and treachery of the Arab." But for them Mr Park would have accompliſhed the utmoſt object of his miſſion, and have reached Tombuctoo, and even Houſſa, with no other danger than what ariſes neceſſarily from the climate, from wild beaſts, and from the poor accommodation afforded in the huts of the hoſpitable Negroes. The wandering Moors, however, have all been taught to regard the Chriſtian name with inconceivable abhorrence; and to conſider it nearly as lawful to murder a European as it would be to kill a dog. It is, therefore, much leſs ſurpriſing that our traveller did not proceed farther along the banks of the Niger, than that he eſcaped the ſnares of ſo relentleſs a people.

MORINDA, is a plant, of which a very meagre deſcription has been given in the *Encyclopædia*, though it is of much importance in oriental commerce. It is cultivated to a great extent in the province of *Malwa* in the Eaſt Indies, where it furniſhes a valuable dye ſtuff; and is thus deſcribed by William Hunter, Eſq; in the fourth volume of the Aſiatic Reſearches:

"It is a tree of a middling ſize; the *root* branchy; the *trunk* columnar, erect, covered with a ſcabrous bark. *Branches*, from the upper part of the trunk, ſcattered; of the ſtructure of the trunk. *Leaves* (terminal) oval, obtuſe, entire (mature), oppoſite, decuſſated, ovate, pointed at both ends, ſmooth, with very ſhort petioles. *Stipules*, lanced, very ſmall, withering. *Peduncles*, f the axils of the leaves, ſolitary, bearing an aggregate flower. *Calyx*, common receptacle roundiſh, collecting the ſeſſile flowers into an irregular head. *Perianth*, moſt entire, ſcarce obſervable above. *Corol*, one petalled, funnel-form. *Tube*, cylindric: *Border*, five cleft; the *diviſions* lanced. *Stamen: Filaments*, five, threadform, ariſing from the tube, and adhering to it through two thirds of their length, a little ſhorter than the tube. *Anthers*, linear, erect. *Piſtil. Germ*, beneath, four celled, containing the rudiments of four ſeeds. *Style*, thread form, longer than the ſtamens. *Stigma*, two-cleft, thickiſh. *Pericarp*, common, irregular, divided on the ſurface into irregular angular ſpaces; compoſed of berries, pyramidal, compreſſed on all ſides by the adjacent ones, and concreted with them; lopped; containing towards the baſe a fleſhy pulp. *Seeds*, in each berry four; towards the point oblong, externally convex, internally angular."

The species here described is the *morinda arborea pedunculis solitariis* of Linnæus. It grows best in a black rich soil, free from stones, in situations moderately moist, not too high, yet sufficiently elevated to prevent the rain water from stagnating, and where a supply of water can be had for the dry months. As the colouring matter, for which alone it is valuable, resides chiefly in the bark of the root, the small twigs, which contain little wood, bear a higher price than the larger pieces. The natives employ it in dyeing a pale red, or clay colour; which Mr Hunter says is more valuable for its durability than for its beauty. They likewise use it in dyeing a dark purple or chocolate colour: but for the process, in both cases, we must refer to the original memoir.

MORION, in botany, a name given by the ancients to a kind of nightshade. See SOLANUM, *Encycl.*

MORION, in ancient mineralogy, a name given to one of the semipellucid gems, more commonly called *pramnion*. It is a stone appearing externally of a fine deep black; but when held up against a candle, or against the sun beams, it gives a very beautiful red in different degrees.

MOSHAIRA, or MOSHAHEREH, pension or allowance in Bengal.

MOSS, the name given in Scotland, and we believe also in some parts of England, to what is more properly called a *morass*, a *fen*, or a *bog*. On the formation of these mosses some conjectures have been hazarded in the *Encyclopædia*, where the reader will likewise find a copious account of the method which has for many years been successfully employed to convert the MOSS OF KINCARDINE into an arable soil, or rather to remove the substance called *moss* or *peat* from the rich soil which is found below it. A method, however, has been invented by Mr John Smith of Swindrig-muir, in the shire of Ayr, for *actually* converting the substance called moss into a vegetable mould, which has been found by experience to carry rich crops of corn, hay, potatoes, &c. Of this gentleman's practice we have the following account in a small pamphlet published in Edinburgh, 1798, by Fairbairn and Dickson.

"The first thing to be done is to mark off, and cut out, proper main or master drains, in order to carry off the superfluous water, taking care to preserve the greatest possible level; which drains are so constructed as to divide the field into inclosures from six to ten Scotch acres. If the moss hangs or declines, the inclosures may be of any dimension whatever. The dimensions of these drains when first made are eight feet wide, by four and a half feet deep, declining to two and a half feet at bottom, and cost at the rate of one shilling per fall of eighteen and a half feet, running measure. The ridges are then to be marked off regularly, six or seven yards broad, formed with the spade in the manner following.

"In the centre of each ridge, a space of about 20 inches is allowed to remain untouched, on each side of which a furrow is opened, and turned upon the untouched space, so as completely to cover it (like what is called the feering of a gathered ridge). Thus begun, the work is continued, by cutting with the spade, in width about 12 inches, and turning it over to appearance as if done with a plough, until you come to the division furrow, which should be two feet wide, cut out and thrown upon the sides of the ridges. The depth of the division furrow is to be regulated by circumstances, according as the moss is wet or dry, but so as to answer the purpose of as it were bleeding the moss, and conducting the water to the main drains.

"It may be here observed, that the success of the aftercrops depends very much upon a proper formation of the ridges. They must not be made too high in the middle, for there they will be too dry like a peat, upon which the lime cannot act, and near the furrows they will be too wet, which is equally prejudicial; they should therefore be constructed with a gentle declivity to the furrows, so as the rain which falls may rather filtrate through the ridge to the furrows than run quickly off the surface.

"The next operation is to top-dress the ridges with lime, at the rate of from four to eight chalders per acre. Five Winchester bushels make a boll, and eight bolls a chalder of shell lime, producing sixteen bolls powdered lime. The quicker the lime is put on after being slacked the better.

"The proper season to prepare the moss for a first crop is early the preceding summer; in that case the lime, aided by the heat, the after rains, and the winter frosts, makes considerable progress in the process of putrefaction, consequently forms a mould to receive the seed.

"Though oats have sometimes succeeded as a first crop, potatoes have been found greatly preferable. The method of planting them is simple, and attended with little expence. The moss, prepared by ridges, and limed as before described, beds for the potatoes are, in the spring, marked off, across the ridges, five or six feet broad, with intermediate spaces of about two feet, as furrows or trenches. The beds are covered over with a thin stratum of dung, about eighteeen single-horse carts to an acre, the cuttings of the potatoes are laid or placed upon the beds, about ten or twelve inches asunder, and the whole covered over with a thin stratum of moss from the intermediate trenches, which is followed by another covering from the trenches when the potatoe plants make their first appearance; the covering in whole four or five inches. In this state they remain without any hoeing till the crop is taken up. The produce on Mr Smith's moss has never been less than from forty to fifty bolls of excellent potatoes, eight Winchester bushels to the boll, and the bushel a little heaped.

"When the potatoe crop is removed, the ridges are again formed as before described, and the division-furrow cleared out. In performing this part of the work, it will naturally occur, that a great part of the manured surface will be buried in filling up the trenches between the potatoe beds: but that is not the case; the workman makes two cuts with the spade, at eighteen inches distance, upon the side of the trench; another, one foot from the edge of it, as deep as the trench; which, instead of turning over, he presses a foot forward into the trench, which is continued the length of it; and when he comes to the other side he does the same, making both meet, and so proceeds; so that no part of the manured surface is thrown down, and the ridge is left in the same form as before the lazy-beds* were made.

"When the potatoe crop is taken off, and the ridges formed as before described, they remain in that state till spring, when oats are sown (a wet or dry season has

* This is a vulgar Scottish phrase for beds of a particular kind of potatoe.

Moss. from experience been found a matter of indifference), and harrowed in with a small harrow drawn by two men. Four men with ease harrow at least one acre one rood per day, two and two by turns with the harrow, and the other two in the interim with spades, smoothing the inequalities, breaking and dividing the mould, and clearing out the division furrows; which last in all operations upon moss are essentially necessary. The early or hot seed oats are always preferred for seed. The late or cold seed runs too much to straw, falls down, and becomes floony, consequently the grain is of mean quality, and unproductive in meal.

"The produce of the first crop of oats after potatoes is seldom less than ten bolls per acre, the Linlithgow boll of six Winchester bushels, and considerably more has been known; as good grain in quality, and meals as well as any in the country. It has been sold when growing, what is called upon the foot, including the straw, from eight to ten pounds per acre. To prepare for a second crop of oats, the ridges must be dug across, and turned over in the manner before described, and the division furrows cleared out as soon as convenient after the first crop is removed.

"Such is the effect of lime in consolidating moss, aided by the draining, that often after the second, and always after the third year, it can be ploughed by horses within two bouts or stitches of the division furrow; and also harrowed by horses, and the crops taken off by carts.

"Five and often six consecutive crops of oats are taken, without any other manure than what it received the first year for potatoes, without any apparent signs of it being exhausted. The produce of the first two crops of oats has been mentioned to be ten bolls, and the third, fourth, fifth, and sixth, produce from six to ten bolls per acre. The moss is now turned into a seeming rich dark brown mould; and what renders it less productive of corn crops the fourth, fifth, and sixth years is, its naturally running into sweet and luxuriant grasses. The soft meadow grass, the daisy, some plaintain, but principally the white clover, are the most prevalent grasses; or more probably it may be ascribed to these crops being ploughed, in place of being dug with the spade, as the former years were. Along with the fifth or sixth crop of oats, rye grass is sown, which, with the natural grasses in general, produce an abundant crop of hay.

"If the moss in the original state has been wet and spongy, it will be found to have subsided some feet after the third or fourth year's operation has been performed; but care must always be taken to deepen, clear out, and keep clear the main drains and the division furrows, to prevent a superabundance of moisture, which would infallibly be the case were they neglected in consequence of, the subsidence of the moss. Indeed moss of all sorts will subside less or more, in proportion as it has been dry or wet in its original state; at the same time, as stated before, care must be taken not to lay it too dry, but to keep in a proper degree of temperature between these two extremes."

By having recourse to the pamphlet from which this extract has been made, the reader may satisfy himself of the real advantages of this species of agriculture. The author calculates, with much apparent fairness, the expence of improvement, and the value of each crop, and concludes that no waste can be improved with equal advantage as moss. It must not, however, be concealed, that we have heard practical farmers, who seemed to be acquainted with the subject, give it as their opinion that this mode of cultivation answers only in mosses of no great depth; though our author affirms that it has with great success been practised by Mr Smith in mosses of the depth of 14 feet.

Motion

MOTION IN FLUIDS. When in the publication of this *Supplement* we had arrived at the title FLUIDS, we were struck with the importance given, in some of the journals, to *The Experimental Researches of Venturi concerning the Principle of the lateral communication of Motion in Fluids, applied to the Explanation of various Hydraulic Phenomena*. Of these researches we intended to lay an abridged account before our readers under the present title; but having examined the work with some attention, we find in it hardly any thing of consequence which the mechanical philosopher may not learn from our articles *RESISTANCE of Fluids* and RIVERS in the *Encyclopædia*. That our readers, however, may find something under a title to which we rashly referred them, we shall, in the words of Nicholson's Journal of Natural Philosophy, &c. inform them what Venturi's work contains.

"This author, who is professor of experimental philosophy at Modena, has introduced an horizontal current of water into a vessel filled with the same fluid at rest. This stream entering the vessel with a certain velocity, passes through a portion of the fluid, and is then received in an inclined channel, the bottom of which gradually rises until it passes over the border or rim of the vessel itself. The effect is found to be, not only that the stream itself passes out of the vessel through the channel, but carries along with it the fluid contained in the vessel; so that after a short time no more of the fluid remains than was originally below the aperture at which the stream enters. This fact is adopted as a principle or primitive phenomenon by the author, under the denomination of the lateral communication of motion in fluids, and to this he refers many important hydraulic facts. He does not undertake to give an explanation of this principle, but shews that the mutual attraction of the particles of water is far from being a sufficient cause to account for it.

The first phenomenon which the author proposes to explain by this established principle, is the emission of a fluid through different adjutages applied to the reservoir which contains it. It is known that the vein of fluid which issues from an orifice or perforation through a thin plate, becomes contracted, so as to exhibit a section equal to about 0,64 of the orifice itself, supposed to be circular; and that the place of the greatest contraction is usually at the distance of one semi-diameter of the orifice itself. If a small adjutage be adapted to the orifice, having its internal cavity of the same conoidal form as the fluid itself affects in that interval, the expenditure is the same as by the simple orifice. But if at the extremity of this adjutage a cylindric tube be affixed, of a greater diameter than that of the contracted vein, or a divergent conical tube, the expence of fluid increases, and may exceed the double of that which passes through the aperture in the thin plate, though the adjutage possess an horizontal or even ascending direction.

By

By the interposition of a small adjutage, adapted to the form of the contracted vein, Venturi ascertained, in the first place, that there is an increase of velocity in the tubes he employed, though the velocity of emission itself be less than that of the stream which issues from a hole in a thin plate. He afterwards proves, by the fact, that the interior velocity and expenditure of fluid, which is increased through tubes, even in the horizontal or ascending direction, is owing to the pressure of the atmosphere. If the smallest hole be made in the side of the tube near the place of contraction of the vein, the increased expenditure does not take place; and when a vertical tube is inserted in such a hole, the lower end of which tube is immersed in water or mercury, it is found that aspiration takes place, and the water or mercury rises; and this aspiration in conical tubes is less in proportion, as the place of insertion of the upright tube is more remote from the section where the greatest contraction would have taken place. And, lastly, the difference between the expenditure of fluid, through an orifice made in a thin plate, and that which is observed through an additional tube, does not take place in vacuo.

The influence of the weight of the atmosphere on the horizontal or ascending flux being thus established, the author considers it as a secondary cause, referable to, and explicable by, his principle of the lateral communication of motion in fluids. In conical divergent tubes, for example, the effect of this lateral communication is, that the central cylindrical jet, having for its basis the section of the contracted vein, carries with it the lateral fluid which would have remained stagnant in the enlarged part of the cone. Hence a vacuum tends to be produced in this enlarged part which surrounds the central cylindric stream; the pressure of the atmosphere becomes active to supply the void, and is exerted on the surface of the reservoir, so as to increase the velocity of the fluid at the interior extremity of the tube.

The author proves, that the velocity or total expenditure of fluid through an aperture of given dimensions, may be increased by a proper adjutage in the proportion of 24 to 10: he applies this result to the construction of the funnels of chimneys. He determines the loss of emitted fluid, which may be sustained by sinuosity in pipes. He shews by experiment, that a pipe which is enlarged in any part affords a much less quantity of fluid than if it were throughout of a diameter equal to that of its smallest section. This, as he remarks, is a circumstance to which sufficient attention has not been paid in the construction of hydraulic machines. It is not enough to avoid elbows and contractions; for it sometimes happens that, by an intermediate enlargement, the whole of the advantage arising from other judicious dispositions of the parts of the machine is lost.

There are two causes of the increase of expenditure through descending pipes. The first is owing to the lateral communication of motion which takes place in descending pipes, in the same manner as in those which possess an horizontal situation; the second arises from the acceleration by gravity which takes place in the fluid while it falls through the descending tube. This second kind of augmentation was known to the ancients, though they possessed no good theory nor decisive experiments respecting it. The author endeavours to establish a theory on the principle of virtual ascension combined with the pressure of the atmosphere. His deductions are confirmed by experiment, in which he has succeeded so far as to separate the two causes of augmentation, and assigned to each their respective degree of influence.

Professor Venturi then proceeds to different objects of enquiry, to which his principle seemed applicable. He gives the theory of the water blowing machine (see *Water Blowing Machine* in this *Suppl.*), and he determines by calculation the quantity of air which one of these machines can afford in a given time. He observes, that the natural falls of water in the mountains always produce a local wind; and he even thinks, that the falling streams in the internal parts of mountains are in some instances the cause of the winds which issue from caves. He proves, by the facts, that it is possible, in certain instances, to carry off, without any machinery, the waters from a spot of ground, though it may be situated on a lower level than that of the channel which is to receive the water.

The whirlpools, or circular eddies of water so frequent in rivers, are, according to the theory of our author, the effect of motion communicated from the parts of the current which are most rapid, to those lateral parts which are least so. In the application of this principle, he points out the circumstances adapted to produce such eddies at the surface or at the bottom of rivers. He concludes, that every movement of this kind destroys a part of the force of the current, and that in a channel through which water constantly flows, the height of this fluid will be greater than it would have been if the dimensions of the channel had been uniformly reduced to the measure of its smallest section.

There is another kind of whirling motion somewhat different in its nature from these last. It is produced in the water of a reservoir, when it is suffered to flow through an horizontal orifice. The author deduces the theory of these vortices from the doctrine of central forces. The form of the hollow funnel, which in this case opens through the fluid of the reservoir, is a curve of the 64th species of the lines of the third order, enumerated by Newton. Theory and experiment both unite here in proving, that it is not only possible, but that there really exists in nature a vortex, the concavity of which is convex towards the axis, and of which the revolutions of its different parts follow the ratio of the square of the distance from the centre. Daniel Bernoulli was in the wrong, in his Hydrodynamics, to reproach Newton for having supposed a vortex to be moved according to this law.

In the last place, the author considers that lateral communication of motion which takes place in the air as well as in the water. This is the cause of such local and partial winds as sometimes blow contrary to the direction of the general wind. It is by virtue of the same principle, that the resonant vibration, excited laterally in the extremity of an organ pipe, is communicated to the whole column of air contained in the pipe itself.

From the same principle, the author deduces the augmentation of force which sound receives in conical divergent tubes, compared with those of a cylindrical form. On this occasion, he points out the remarkable diffe-

differences which appear to take place between the resonant vibrations of air contained in a tube, and the sonorous pulsations propagated through the open atmosphere. See *Speaking Trumpet*, Encycl.

In an appendix, Venturi relates different experiments which he has made to determine the convergence and velocity of the fluid filaments which press forward to issue out of a reservoir by an orifice through a thin plate. He proves, by a very clear experiment, that the contraction of the vein is made at a greater distance from the orifice under strong than under weak pressures. He explains why, in a right lined orifice, the sides of the contracted vein correspond with the angles of the orifice and the angles with the sides. He examines the expenditure through a tube, the extremity of which is thrust into the reservoir itself, according to the method of Borda in the Memoirs of the Academy of Sciences for the year 1766."

For a full account of the author's experiments, and his deductions from them, we refer the reader either to the original work, intitled, *Recherches expérimentales sur le Principe de la Communication latérale du Mouvement dans les Fluides, appliqué à l'Explication de différens Phénomènes hydrauliques. Par le Citoyen J. B. Venturi, Professeur de Physique expérimentale à Modène, Membre de la Societé Italienne, &c. &c. A Paris chez Houel et Ducros, Rue du Bacq,* N° 940—*Théophile Barrois, Rue Haute-feuille,* N° 22. *Ann.* VI. 1797—or to the 2d and 3d vols of the valuable Journal from which this abstract is taken

MOURZOUK, the capital of Fezzan in Africa, is situated on a small river, and supplied with water from a multitude of springs and wells. Being formerly built of stone, it still retains the appellation of a Christian town; and the medley which it presents to the eye, of the vast ruins of ancient buildings, and the humble cottages of earth and sand that form the dwellings of its present Arab inhabitants, is singularly grotesque and strange. It is surrounded by a high wall, which not only affords the means of defence, but enables the government to collect, at its three gates, a tax on all goods (provisions excepted) that are brought for the supply of its people. A caravan sets out annually from Mesurata to this place; and hence the Fezzaners themselves dispatch every year a caravan to Cashna and another to Bornou. For the latitude of Mourzouk, see Fezzan in this *Suppl.* Dr Brookes, in his Gazetteer, places it in 15° 5' E. Long.

MOWAZZEF, in Bengal, fixed revenue.

MOZART, the celebrated German musician, was born at Salzburg in the year 1756. His father was also a musician of some eminence, but not to be compared with the son; of whom we have the following account in one of the monthly miscellanies, taken by Mr Bushby from some biographical sketches by two eminent German professors.

At the age of three years, young Mozart, attending to the lessons which his sister, then seven years old, was receiving at the harpsichord, he became captivated with harmony; and when she had left the instrument, he would instantly place himself at it, find the thirds, sound them with the liveliest joy, and employ whole hours at the exercise. His father, urged by such early and striking indications of genius, immediately began to teach him some little airs; and soon perceived that his pupil improved even beyond the hopes he had formed of him. Half an hour was generally sufficient for his acquiring a minuet or a little song, which, when once learned, he would of himself perform with taste and expression.

At the age of six years he had made such a progress as to be able to compose short pieces for the harpsichord, which his father was obliged to commit to paper for him. From that time nothing made any impression upon him but harmony; and infantine amusements lost all their attractions unless music had a share in them. He advanced from day to day, not by ordinary and insensible degrees, but with a rapidity which hourly excited new surprise in his parents—the happy witnesses of his progress.

His father returning home one day with a stranger, found little Mozart with a pen in his hand. "What are you writing," said he? "A concerto for the harpsichord," replied the child. "Let us see it (rejoined the father); it is a marvellous concerto without doubt." He then took the paper, and saw nothing at first but a mass of notes mingled with blots of ink by the mal address of the young composer, who, unskilled in the management of the pen, had dipped it too freely in the ink; and having blotted and smeared his paper, had endeavoured to make out his ideas with his fingers; but on a closer examination, his father was lost in wonder; and his eyes delighted and flowing with tears, became rivetted to the notes. "See (exclaimed he to the stranger) how just and regular it all is! but it is impossible to play it; it is too difficult." "It is a concerto (said the child), and must be practised till one can play it. Hear how this part goes." He then sat down to perform it; but was not able to execute the passages with sufficient fluency to do justice to his own ideas. Extraordinary as his manual facility was universally allowed to be for his age, it did not keep pace with the progress of his knowledge and invention. Such an instance of intellectual advancement, in a child only six years of age, is so far out of the common road of nature, that we can only contemplate the fact with astonishment, and acknowledge, that the possible rapidity of mental maturation is not to be calculated.

In the year 1762, his father took him and his sister to Munich, where he performed a concerto before the elector, which excited the admiration of the whole court; nor was he less applauded at Vienna, where the emperor called him the *little sorcerer*.

His father gave him lessons only on the harpsichord; but he privately taught himself the violin; and his command of the instrument afforded the elder Mozart the utmost surprise, when he one day at a concert took a second violin, and acquitted himself with more than passable address. True genius sees no obstacles. It will not therefore excite our wonder, if his constant success in whatever he attempted begot an unbounded confidence in his own powers; he had even the *laudable* hardihood to undertake to qualify himself for the *first* violin, and did not long remain short of the necessary proficiency.

He had an ear so correct, that he felt the most minute discordancy; and such a fondness for study, that it was frequently necessary to take him by force from the instrument. This love of application never diminished. He every day passed a considerable time at his harpsichord, and generally practised till a late hour at night.

Mozart. night. Another characteriſtical trait of real genius; always full of its object, and loſt as it were in itſelf.

In the year 1763 he made, with his father and ſiſter, his firſt grand muſical journey. He viſited Paris; and was heard by the French court in the chapel-royal at Verſailles, where his talent on the organ was admired even more than on the harpſichord. At Paris the muſical travellers gave two concerts, which procured them the higheſt reputation, and the diſtinction of public portraits. It was here that a ſet of ſonatas for the harpſichord, ſome of his earlieſt compoſitions, were engraved and publiſhed.

From Paris they went to London, where they alſo gave two concerts, conſiſting of ſymphonies compoſed by young Mozart, who even at that early age ſang alſo with much expreſſion, and practiſed publicly with his ſiſter. Mozart played already at ſight, and in a concert, at which the king was one of his auditors, a baſs being placed before him as a *ground*, immediately applied to it a moſt beautiful melody. Thoſe who are beſt acquainted with the extent of ſuch a taſk, will be the moſt aſtoniſhed at ſuch mature familiarity with the intricacies of the ſcience, and ſuch prompt and ready invention in ſo juvenile a mind.

From London, where Mozart alſo publiſhed ſix ſonatas for the harpſichord, the muſical family went to Holland, thence again to France, and in 1766 returned to Salzburg. There this extraordinary youth remained more than a year in perfect repoſe; devoting the whole of his time to the ſtudy of compoſition, the principles of which he ſcrutinized with the depth and penetration of confirmed manhood. Emmanuel Bach, Haſſe, and Handel, were his chief guides and models; though he by no means neglected the old Italian maſters.

In 1768 he again viſited Vienna, where Joſeph II. engaged him to ſet to muſic a comic opera, entitled, *La Finta Semplice*, which obtained the approbation of Haſſe and Metataſio. At the houſe of the prince of Kaunitz, it often happened that the firſt Italian air which came to hand would be given him, that in the preſence of the company he might add to it accompaniments for numerous inſtruments; which he would write in the firſt ſtyle of excellence, and without the leaſt premeditation. This is at once a proof with what acuteneſs of obſervation he had liſtened to the muſic of the beſt maſters; how intimate he had already rendered himſelf with the characters, capacities, and effects of the different inſtruments; and what ſkill he had acquired in that abſtruſe art of mixed combination which, while it calculates the conjoint effect of ſounds, as they regard the eſtabliſhed laws of harmony, accommodates the different parts to the ſcales, tones, and powers of the reſpective inſtruments by which they are to be executed. It was at this time alſo that, although but twelve years of age, he compoſed the muſic for the conſecration of the church of orphans, at the performance of which he himſelf preſided.

In 1769 Mozart again returned to Salzburg, where he became *maitre de concert*. Not having yet ſeen Italy, in December of the ſame year he ſet out for that ſeat of the fine arts. Thoſe talents which had already excited the admiration of Germany, France, and England, now awakened in that land of muſical taſte the moſt lively enthuſiaſm.

In 1771 he had no ſooner given perſonal proofs of his genius, than *la ſcrittura* for the following carnival was conferred upon him. He viſited Bologna, then as famous for harmonic excellence as Naples, where the celebrated theoriſt Martini was amazed to ſee a German boy work and execute the theme of a fugue which he preſented to him, in the extraordinary ſtyle in which Mozart acquitted himſelf. He next went to Florence. Florence even enhanced the eulogiums which Bologna had laviſhed upon him.

During the holy week he arrived at Rome, and aſſiſted at the *Miſerere* in the Sixtine chapel: which performance is juſtly conſidered as the *ne plus ultra* of vocal muſic. This circumſtance claims particular notice, as inducing a proof of another faculty of his mind, only to be equalled by thoſe wonderful powers which he had already demonſtrated. He was prohibited from taking a copy of this *Miſerere*, and therefore piqued himſelf on retaining it in his memory. Having heard it with attention, he went home, made out a manuſcript from recollection, returned the next day to the chapel, heard the piece a ſecond time, corrected the rough draught, and produced a tranſcript which ſurpriſed all Rome. This *Miſerere* formed a *ſcorer* numerous in its parts, and extremely difficult of execution. His mind had embraced and retained the whole!

He ſoon after received from the Pope the order of the gilt ſpur; and at Bologna was complimented, by an unanimous deciſion, with the title of *Member and Maſter of the Phil-harmonic Academy*. As a proof, *pro forma*, of his qualifications for this academical honour, a fugue, for four voices, in the church ſtyle, was required of him, and he was ſhut up alone in his chamber. He completed it in half an hour, and received his diploma. This evinced that he poſſeſſed an imagination conſtantly at his command, and that his mind was ſtored with all the riches of his beloved ſcience.

The opera which he compoſed for Milan was called *Mithridates*. This piece procured him *la ſcrittura* for the grand opera of the carnival of 1773, which was his *Lucio Sulla*. At length, after a tour of fifteen months, he returned to Salzburg.

In 1771 Mozart viſited Paris; but not reliſhing the muſic of that capital, he ſoon quitted it, and returned to his domeſtic comforts. In 1781, at the requeſt of the elector of Bavaria, he compoſed the opera of *Idomeneo* for the carnival of that year. The general merit of this opera is ſo great, that it might ſerve alone for the baſis of a diſtinguiſhed reputation. At his twenty-fifth year he was invited to Vienna, where he continued ſpreading, as from a centre, the taſte of his compoſitions through all Germany, and the luſtre of his name over the whole of Europe.

Of all the virtuoſi of the piano forte who then crowded Vienna, Mozart was much the moſt ſkilful. His finger was extraordinarily rapid and taſteful, and the execution of his left hand exceeded every thing that had before been heard. His touch was replete with delicacy and expreſſion; and the profound ſtudy he had beſtowed on his art, gave his performance a ſtyle the moſt brilliant and finiſhed. His compoſitions had a rapid circulation; and in every new piece the connoiſſeurs were ſtruck with the originality of its caſt, the novelty of the paſſages, and the energy of the effect.

Joſeph II. ſolicitous for the perfection of the German opera, engaged Mozart to compoſe a piece. He accordingly

Mozart. cordingly produced *L'enlevement du Serail;* performed for the first time in 1782. It excited the jealousy of the Italian company, who therefore ventured to cabal against it. The emperor, addressing himself to the composer, said, "It is *too fine* for our ears, my dear Mozart, and most *charmingly crowded* with notes." "Precisely what it ought to be," replied the spirited musician, who justly suspected that this remark had been suggested to Joseph by the envious Italians. "Though I cannot describe, as an auricular evidence, (says the faithful author of the biography), the applauses and the admiration which this opera produced at Vienna, yet I have witnessed the enthusiasm it excited at Prague among all the connoisseurs, as well as among those whose ears were less cultivated. It was said, that all which had been heard before was not music: it drew the most overflowing audiences: every body was amazed at its new traits of harmony, and at passages so original, and till then so unheard from wind instruments."

The cautious reader will perhaps hesitate to admit, in its fullest extent, this account by the author of the biography; but even after an allowance for some exaggeration, the most phlegmatic will grant that much must have been atchieved by this great master, to afford a basis for so glowing a picture of the merit and success of *L'enlevement du Serail.* During the composition of this opera, he married Mademoiselle Weber, a distinguished virtuosa; and the piece was supposed to owe to this felicitous circumstance much of that endearing character, that tone of tenderness, and that expression of the softer passions, which form its principal attractions.

"The Marriage of Figaro," which was in the highest repute at all the theatres, was in the year 1787 transformed into an Italian opera; and Mozart, at the instance of the emperor, set it to music. This piece was highly received everywhere, and kept possession of the theatre at Prague during almost the whole of the winter in which it first appeared: numerous extracts were made from it, and the songs and dances of Figaro were vociferated in the streets, the gardens, and the taverns. Mozart came that very winter to Prague, and performed in public on the piano forte. His auditors at all times listened to him with admiration; but whenever he played extempore, and indulged the spontaneous and uninterrupted sallies of his fancy, which he sometimes would for more than half an hour, every one was seized with the most enthusiastic raptures, and acknowledged the unrivalled resources of his imagination. About this time the manager of the theatre contracted with him for the composition of a new opera, which, when produced, was called *Il dissoluto Punito*, or *Don Giovanni.* His reputation was now so exalted, that the Bohemians piqued themselves on the circumstance that this opera was composed for their entertainment.

But this fame, this great and universal applause, had not yet produced to the admired artist any solid advantages; he had obtained no place, no settled income; but subsisted by his operas, and the instructions and occasional concerts which he gave. The profits of these proved insufficient for the style which he was obliged to support; and his finances became much deranged. The critical situation in which he now found himself, made him resolve to quit Vienna, and seek an asylum in London; to which metropolis he had often been invited; but Joseph nominating him *compositeur de la chambre*, though, with a very inadequate salary, he was induced to accept it; and Germany had the advantage of retaining him.

It is lamentable that premature genius too rarely enjoys a long career: The acceleration of nature in the mental powers seems to hurry the progress of the animal œconomy, and to anticipate the regular close of temporal existence.

In the year 1791, Mozart, just after he had received the appointment of *Maitre de chapelle* of the church of St Peter, and when he was only thirty-five years of age, paid the last tribute; and left the world at once to admire the brilliancy, and lament the shortness of his earthly sojournment.

Indefatigable, even to his death, he produced, during the last few months of his life, his three great master pieces *La Flutte Enchantée*, *La Clemence de Titus*, and a *Requiem*, his last production. *La Flutte Enchantée* was composed for one of the theatres at Vienna; and no dramatic *Olio* could ever boast a greater success. Every air struck the audience with a new and sweet surprise; and the *tout ensemble* was calculated to afford the deepest and most varied impressions. This piece had, in fact, so great a number of successive representations, that for a long time it was unnecessary to consult the opera-bill; which only announced a permanent novelty. And the airs selected from it, and repeated throughout the empire, as well in the cottage as in the palace, and which the echoes have resounded in the most distant provinces, favoured the idea that Mozart had actually the design to enchant all Germany with his *Flutte Enchantée.*

La Clemence de Titus was requested by the states of Bohemia for the coronation of Leopold. The composer began it in his carriage during his route to Prague, and finished it in eighteen days.

Some circumstances attending the composition of the piece which we have already mentioned as the last effort of his genius, are too interesting to be omitted. A short time before his death, a stranger came to him with the request that he would compose, as speedily as possible, a *requiem* for a catholic prince, who, perceiving himself on the verge of the grave, wished, by the execution of such a piece, to soothe his mind, and familiarise it to the idea of his approaching dissolution. Mozart undertook the work; and the stranger deposited with him as a security 400 ducats, though the sum demanded was only 200. The composer immediately began the work, and during its progress felt his mind unusually raised and agitated. He became at length so infatuated with his *requiem*, that he employed not only the day, but some hours of the night in its composition. One day, while he was conversing with Madame Mozart on the subject, he declared to her that he could not but be persuaded that it was for himself he was writing this piece. His wife, distressed at her inability to dissipate so melancholy an impression, prevailed on him to give her the *score.* He afterwards appearing somewhat tranquillized, and more master of himself, she returned the *score* to him, and he soon relapsed into his former despondency. On the day of his death he asked for the *requiem*, which was accordingly brought to his bed: "Was I not right (said he), when I declared that it

Mozart. was for myself I was composing this funeral piece?" And the tears trickled from his eyes. This production of a man, impressed during its composition with a presentiment of his approaching death, is *unique* in its kind, and contains passages which have frequently drawn tears from the performers.

Only one complaint escaped him during his malady: "I must quit life (said he), precisely at the moment when I could enjoy it, free from care and inquietude; at the very time when, independent of sordid speculations, and at liberty to follow my own principles and inclinations, I should only have to write from the impulses of my own heart: and I am torn from my family just when in a situation to serve it." Mozart, at the time of his death, was considerably involved in debt; but Vienna and Prague disputed the honour of providing for his widow and children.

The countenance of this great master did not indicate any thing uncommon. He was small of stature; and, except his eyes, which were full of fire, there was nothing to announce superiority of talent. His air, unless when he was at the harpsichord, was that of an absent man. But when he was performing, his whole physiognomy became changed: a profound seriousness recalled and fixed his eyes; and his sentiments were expressed in every movement of his muscles. Never has a musician more successfully embraced the whole extent of his art, and shone with greater lustre in all its departments. His great operas, no less than his most simple songs; his learned symphonies as well as his airy dances—all carry the stamp of the richest imagination, the deepest sensibility, and the purest taste. All his works develope the originality of his genius; and imply a mind great and exalted; an imagination which strikes out for itself a new course. He therefore merits to be ranked with that small number of original geniuses, those *phenomena splendida*, who form an epoch in their art, by carrying it to perfection, or giving it an unknown career.

It is in the employment of wind instruments that Mozart displays his greatest powers. His melody is always simple, natural, and full of force; and expresses with precision the sentiments and individual situations of his personages. He wrote with extraordinary facility. "*La Clemence de Titus*," the reader will recollect, cost him the study of but eighteen days; and his *requiem*, which is equal in length to an opera, was produced in four weeks. It is also worthy of remark, that the overture to his *Don Giovanni* was not begun till the night before the piece was to be performed. At midnight, after having devoted the evening to amusement, he locked himself up in his study, and composed it in a few hours. His memory was wonderfully retentive, as we may judge from his copying by recollection the *miserere* at Rome. But a fact equally astonishing is, that, soon discovering the eagerness of people to procure his works, and fearful that they might be pirated, it was his constant custom to transcribe from the *scores* of his sonatas only a part for one hand, and at the public performance to supply the other by memory.

He very early began to display that true dignity of an artist which renders him indifferent to the praises of those who are unqualified to judge. The commendations of the ignorant great he never considered as fame. His hearers, whether the wealthy or the titled, must have acquired some credit for their judgment before he could be ambitious of their applause. Indeed he entertained so just a sense of scientific elevation and importance, that he would insist upon respect. And the least noise or idle babble, while he was at the instrument, excited a displeasure which he was too indignant to conceal. Once, to the honour of his feelings, he suddenly rose from his seat, and left his inattentive auditory to experience the keen though silent reproach of insulted genius.

His mind was by no means unlettered; nor was it embellished with one science alone. He was master of several languages, and had made considerable progress in the mathematics. He was honest, mild, generous, full of frankness; and with his friends had an air at once amiable, gay, and free from the least tincture of pedantry.

Far from viewing with envy the success of others, a weakness too closely interwoven in the general nature of man, he was always just to the talents of his fellow professors; and valued and respected merit wherever he found it; a clearer proof of which cannot be adduced than the following circumstance: At a concert, where a new piece composed by the celebrated Joseph Haydn was performed, a certain musician, who never discovered any thing worthy of praise except in his own productions, did not fail to criticise the music; exclaiming to Mozart, "There now! there again! why, that is not what *I* should have done:" "No; neither should I (replied Mozart); but do you know why? Because neither you nor I should have been able to conceive it."

Mumbo. MUMBO-JUMBO, a strange bugbear employed by the Pagan Mandingoes (see MANDING, *Suppl.*) for the purpose of keeping their women in subjection. Polygamy being allowed among these people, every man marries as many wives as he can conveniently maintain; and the consequence is, that family quarrels sometimes rise to such a height, that the husband's authority is not sufficient to restore peace among the ladies. On these occasions, the interposition of *Mumbo-Jumbo* is called in; and it is always decisive. This strange minister of justice, who is either the husband himself, or some person instructed by him, disguised in a sort of masquerade habit, made of the bark of trees, and armed with the rod of public authority, announces his coming by loud and dismal screams in the woods near the town. He begins the pantomime at the approach of night; and as soon as it is dark, he enters the town, and proceeds to the *Bentang* or market-place, at which all the inhabitants immediately assemble.

It may easily be supposed that this exhibition is not much relished by the women; for as the person in disguise is entirely unknown to them, every married female suspects that the visit may possibly be intended for herself; but they dare not refuse to appear when they are summoned; and the ceremony commences with songs and dances, which continue till midnight, about which time Mumbo fixes on the offender. This unfortunate victim being thereupon immediately seized, is stripped naked, tied to a post, and severely scourged with Mumbo's rod, amidst the shouts and derision of the whole assembly; and it is remarkable, that the rest of the women are the loudest in their exclamations on this occasion against their unhappy sister. Daylight puts an end to this indecent

indecent and unmanly revel. It is truly astonishing that the women should be deluded by so clumsy an imposture, and that the men should so faithfully keep their own secret. That the women are deluded seems evident; for Mr Park assures us, that the dress of Mumbo is suffered to hang on a tree at the entrance of each town; which could hardly be the case, if the women were not persuaded that it is the dress of some supernatural being.

MUNSHY, a Persian secretary or writer.

MUNSUB, in the language of Bengal, a dignity or command conferred by the emperor.

MUNSUBDAR, a dignitary or commander.

MURRAY (William), afterwards Earl of Mansfield and Lord Chief Justice of England, was the fourth son of David Viscount Stormont. He was born on the 2d day of March 1705 at Perth, in the kingdom of Scotland, of which kingdom his father was a peer. His residence in Scotland, however, was of short duration; for he was carried up to London at the early age of three years. Hence his total exemption from the peculiarities of the dialect of his native country.

At the age of fourteen he was admitted as a king's scholar of Westminster school; and during his residence in that seminary, says his contemporary Bishop Newton, he gave early proofs of his uncommon abilities, not so much in his poetry, as in his other exercises; and particularly in his declamations, which were sure tokens and prognostics of that eloquence which grew up to such maturity and perfection at the bar, and in both houses of parliament. At the election in May 1723, he stood first on the list of those gentlemen who were sent to Oxford, and was entered of Christ Church, June the 18th, in that year. In the year 1727 he had taken the degree of B. A. and on the death of King George the First, was amongst those of the university who composed verses on that event.

In April 1724 he was admitted a student of Lincoln's Inn, though he still continued to reside much in the university; where, on the 26th of June 1730, he took the degree of M. A. and soon afterwards left Oxford, determined to make the tour of Europe before he should devote himself seriously to business. About this period he wrote two letters to a young nobleman on the study of ancient and modern history, which are published by his biographer Mr Holliday, and shew how amply his own mind was then stored with general literature.

On his return to England he commenced his legal studies; but proceeded not in the way then usually adopted, of labouring in the chambers of a special pleader, or copying (to use the words of Blackstone) the trash of an attorney's office. Being blessed with the powers of oratory in their highest perfection, and having soon an opportunity of displaying them, he very early acquired the notice of the chancellor and the judges, as well as the confidence of the inferior practisers. How much he was regarded in the house of lords, Pope's well-known couplet will prove:

> Grac'd as thou art with all the power of words,
> So known, so honour'd at the house of lords.

The graces of his elocution, however, produced their usual effect with a certain class of people, who would not believe that such bright talents could associate with the more solid attainments of the law, or that a man of genius and vivacity could be a profound lawyer. As Pope observed at that time,

> The Temple late two brother serjeants saw,
> Who deem'd each other oracles of law;
> With equal talents these congenial souls,
> One lull'd the exchequer, and one stunn'd the rolls;
> Each had a gravity would make you split,
> And shook his head at Murray as a wit.

It is remarkable that this ridiculous prejudice accompanied Lord Mansfield to the end of his judicial life, in spite of daily proofs exhibited in the court of King's Bench and in the House of Lords, of very profound knowledge of the abstrusest points of jurisprudence. Lord Chesterfield has given his sanction to this unfounded opinion. In a letter to his son, dated Feb. 12. 1754, he says, "The present Solicitor General Murray has less law than many lawyers, but he has more practice than any, merely upon account of his eloquence, of which he has a never-failing stream."

In the outset of Lord Mansfield's life, it will be the less surprising, that a notion should have been entertained of his addicting himself to the pursuits of Belles Lettres too much, when the regard shewn to him by Mr Pope, who despotically ruled the regions of literature at that period, is considered. That great Poet seemed to entertain a particular affection for our young lawyer, and was eager to shew him marks of his regard. He addressed to him his imitation of the 6th Epistle of the First Book of Horace; and even condescended to become his master in the art of elocution. "Mr Murray (says his biographer) was one day surprised by a gentleman of Lincoln's Inn, who could take the liberty of entering his rooms without the ceremonious introduction of a servant, in the singular act of practising the graces of a speaker at a glass, while Pope sat by in the character of a friendly preceptor. Mr Murray, on this occasion, paid that poet the handsome compliment of, *Tu es mihi Mæcenas* (A)."

Whatever propensities this sprightly lawyer might have towards polite literature, he did not permit them to divert his attention from his profession. He soon distinguished himself in an extraordinary manner, as may be seen by those who are conversant with, or choose to refer to the Books of Reports. In the year 1736, the murder of Captain Porteous by a mob in Edinburgh, after he had been reprieved, occasioned a censure to fall on that city, and a bill of pains and penalties was brought into Parliament against the Lord Provost and the corporation; which, after various modifications, and a firm and unabated opposition in every stage of its progress, passed into a law. In both Houses Mr Murray was employed as an advocate, and so much to the satisfaction of his clients, that afterwards, in September 1743, he was presented with the freedom of Edinburgh in a gold box, professedly, as it was rela-

(A) It is thus that eminence is attained even by genius, and Mr Murray was properly employed, though we do not clearly perceive the use of the glass, when his master was watching all his gestures.

red, for his signal services by his speeches to both Houses of Parliament in the conduct of that business.

On the 24th of November 1738, he had married Lady Elizabeth Finch, daughter of the Earl of Winchelsea, and in the month of November 1742, was appointed Solicitor General in the place of Sir John Strange, who resigned (B). He likewise was chosen to represent the town of Boroughbridge in Parliament, for which place he was also returned in 1747 and 1754.

In the month of March 1746-7 he was appointed one of the managers for the impeachment of Lord Lovat by the House of Commons, and it fell to his lot to observe on the evidence previous to the Lords giving their judgment. This task he executed with so much candour, moderation, and gentleman-like propriety, that Lord Talbot, at the conclusion of his speech, paid him the following compliment: "The abilities of the learned manager who just now spoke, never appeared with greater splendour than at this very hour, when his candour and humanity has been joined to those great abilities which have already made him so conspicuous, that I hope one day to see him add lustre to the dignity of the first civil employment in this nation." Lord Lovat himself also bore testimony to the abilities of his adversary: "I thought myself (says his lordship) very much loaded by one Murray (C), who your Lordships know was the bitterest evidence there was against me. I have since suffered by another Mr Murray, who, I must say with pleasure, is an honour to his country, and whose eloquence and learning is much beyond what is to be exprest by an ignorant man like me. I heard him with pleasure, though it was against me. I have the honour to be his relation, though perhaps he neither knows it nor values it. I wish that his being born in the North may not hinder him from the preferment that his merit and learning deserve."

During the time that Mr Murray continued in office, he supported, with great ability, the administration with which he was connected; and, of course, rendered himself obnoxious to those who were in opposition. Nothing, however, could be urged either against his public conduct or his private life; but he was involved in some trouble by an ill-devised tale, concurring with the known principles of the family of Stormont, to make him suspected of Jacobitism. Of this affair, a full and particular account is given by the late Lord Melcombe in the following words:

"Messrs Murray, Fawcett, and Stone, were much acquainted, if not school-fellows, in earlier life. Their fortune led them different ways; Fawcett's was to be a country lawyer and recorder of Newcastle. Johnson, now Bishop of Gloucester, was one of their associates. On the day the King's birth-day was kept, they dined at the Dean of Durham's at Durham; this Fawcett, Lord Ravensworth, Major Davison, and one or two more, who retired after dinner into another room. The conversation turning upon the late Bishop of Gloucester's preferments, it was asked who was to have his prebend of Durham? The Dean said, that the last news from London was, that Dr Johnson was to have it: Fawcett said, he was glad that Johnson got off so well, for he remembered him a Jacobite several years ago, and that he used to be with a relation of his who was very disaffected, one Vermon, a mercer, where the Pretender's health was frequently drunk. This passing among a few familiar acquaintance, was thought no more of at the time: it spread, however, so much in the North (how I never heard accounted for), and reached town in such a manner, that Mr Pelham thought it necessary to desire Mr Vane, who was a friend to Fawcett, and who employed him in his business, to write to Fawcett, to know if he had said this of Johnson, and if he had, if it was true.

"This letter was written on the 9th of January; it came to Newcastle the Friday following. Fawcett was much surprised; but the post going out in a few hours after its arrival, he immediately acknowledged the letter by a long, but not very explicit, answer. This Friday happened to be the club day of the neighbouring gentlemen at Newcastle. As soon as Lord Ravensworth, who was a patron and employer of Fawcett, came into the town, Fawcett acquainted him with the extraordinary letter he had received; he told him that he had already answered it; and being asked to shew the copy, said he kept none; but desired Lord Ravensworth to recollect if he held such a conversation at the Deanry of Durham the day appointed for the birth-day. Ravensworth recollected nothing at all of it: they went to the club together, and Ravensworth went the next morning to see his mother in the neighbourhood, with whom he staid till Monday; but this thing of such consequence lying upon his thoughts, he returned by Newcastle. He and Fawcett had another conversation; and in endeavouring to refresh each other's memory about this dreadful delinquency of Johnson, Fawcett said he could not recollect positively at such a distance of time, whether Johnson drank these healths, or had been present at the drinking of them, but that Murray and Stone had done both several times. Ravensworth was excessively alarmed at this with relation to Stone, on account of his office about the prince; and thus the affair of Johnson was quite forgotten, and the episode became the principal part. There were many more conferences between Ravensworth and Fawcett

Murray.

(B) On this occasion a doggrel poem was published by one Morgan, a person then at the bar, entitled, "The Causidicade," in which all the principal lawyers were supposed to urge their respective claims to the post. At the conclusion it is said,

> Then Murray, prepar'd with a fine panegyric
> In praise of himself, would have spoke it like Garrick;
> But the President stopping him said, "As in truth
> Your worth and your praise is in every one's mouth,
> 'Tis needless to urge what's notoriously known,
> The office, by merit, is your's all must own;
> The voice of the public approves of the thing,
> Concurring with that of the Court and the King."

(C) One of the evidences against him.

Murray. ect upon this subject, in which the latter always persisted that Stone and Murray were present at the drinking, and did drink those healths. It may be observed here, that when he was examined upon oath, he swore to the year 1731 or 1732, at latest. Fawcett comes up as usual about his law business, and is examined by Messrs Pelham and Vane, who never had heard of Murray or Stone being named: he is asked, and answers only with relation to Johnson, never mentioning either of the others; but the love of his country, his king, and posterity, burned so strongly in Ravensworth's bosom, that he could have no rest till he had discovered this enormity. Accordingly, when he came to town, he acquainted the ministry and almost all his great friends with it, and insisted upon the removal of Stone. The ministry would have slighted it as it deserved; but as he persisted, and had told so many of it, they could not help laying it before the king, who, though he himself slighted it, was advised to examine it; which examination produced this most injudicious proceeding in parliament *."

* Lord Melcombe's Diary, p. 210.

This is Lord Melcombe's account; and the same author informs us, that Mr Murray, when he heard of the committee being appointed to examine this idle affair, sent a message to the king, humbly to acquaint him, that if he should be called before such a tribunal on so scandalous and injurious an account, he would resign his office, and would refuse to answer. It came, however, before the House of Lords, 22d January 1753, on the motion of the Duke of Bedford.

The debate was long and heavy, says Lord Melcombe; the Duke of Bedford's performance moderate enough; he divided the House, but it was not told, for there went below the bar with him the Earl Harcourt, Lord Townshend, the Bishop of Worcester, and Lord Talbot only. The Bishop of Norwich and Lord Harcourt both spoke, not to much purpose; but neither of them in the least supported the Duke's question.

Upon the whole, Lord Melcombe concludes, "It was the worst judged, the worst executed, and the worst supported point that I ever saw of so much expectation."

The King, his late Majesty, viewed it in its true light; and is reported to have said, "Whatever they were when Westminster boys, they are now my very good friends." He was likewise, as we have been informed by a gentleman connected with the family of Stormont, so delighted with Mr Murray's speech in his own vindication, that he desired to have a copy of it, as a model of dignified and candid eloquence. Fawcett, the original author of the story, seems indeed to have been a very sneaking knave, totally unworthy of credit. Bishop Johnson, who was overlooked in the turmoil, excited by the supposed guilt of Murray and Stone (see STONE, in this *Suppl.*), went to Fawcett's chambers in the Temple, and desired an interview. Being told by the servant that his master was not at home, he renewed his visit very early next morning, and declared his resolution to wait till Mr Fawcett should rise, the laundress having inadvertently confessed that he was still in bed. Fawcett, upon this, left his thorny pillow with reluctance; for something sharper than thorns (says Mr Holliday) awaited him, which he could not now possibly avoid. The result of the interview produced expressions of deep contrition, together with a letter, addressed to the Lord Bishop of Gloucester, acknowledging, in the most explicit terms, that his Lordship was innocent of the charge which he had been the instrument of bringing against him.

Murray.

On the advancement of Sir Dudley Rider to the chief justiceship of the King's Bench in 1754, Mr Murray succeeded him as attorney general; and on his death, November 1756, again became his successor as chief justice, when he was created Baron of Mansfield, in the county of Nottingham, with remainder to the heirs male of his body lawfully begotten.

As soon as Lord Mansfield was established in the King's Bench, he began to make improvements in the practice of that court. On the 12th of November, four days after he had taken his seat, he made a very necessary regulation, observing, "Where we have no doubt, we ought not to put the parties to the delay and expence of a farther argument; nor leave other persons, who may be interested in the determination of a point so general, unnecessarily under the anxiety of suspence."

The anxiety of suspence, from this period, was no longer to be complained of in the court of King's Bench. The regularity, punctuality, and dispatch of the new chief justice, afforded such general satisfaction, that they, in process of time, drew into that court most of the causes which could be brought there for determination.

Sir James Burrows says, "I am informed, that at the sittings for London and Middlesex only, there are not so few as 800 causes set down in a year, and all disposed of. And though many of them, especially in London, are of considerable value, there are not more, upon an average, than between 20 and 30 ever heard of afterwards in the shape of special verdicts, special cases, motions for new trials, or in arrest of judgment. Of a bill of exceptions there has been no instance (I do not include judgments upon criminal prosecutions; they are necessary consequences of the convictions). My reports give but a very faint idea of the extent of the whole business which comes before the court: I only report what I think may be of use as a determination or illustration of some matter of law. I take no notice of the numerous questions of fact which are heard upon affidavits (the most tedious and irksome part of the whole business). I take no notice of a variety of contestations, which, after having been fully discussed, are decided without difficulty or doubt. I take no notice of many cases which turn upon a construction so peculiar and particular, as not to be likely to form a precedent for any other case. And yet, notwithstanding this immensity of business, it is notorious, that, in consequence of method, and a few rules which have been laid down to prevent delay (even where the parties themselves would willingly consent to it), nothing now hangs in court. Upon the last day of the very last term, if we exclude such motions of the term as by desire of the parties went over of course as peremptories, there was not a single matter of any kind that remained undetermined, excepting one case relating to the proprietary Lordship of Maryland, which was professedly postponed on account of the present situation of America. One might speak to the same effect concerning the last day of any former term for some years backward."

The same author also informs us, that, excepting two cases,

Murray. cases, there had not been, from the 6th of November 1756 to the time of his then present publication, 26th May 1776, a final difference of opinion in the court in any case, or upon any point whatsoever. "It is remarkable, too (he adds), that, excepting these two cases, no judgment given during the same period has been reversed, either in the exchequer chamber or in parliament: and even these reversals were with great diversity of opinion among the judges." Of the two cases here mentioned, one was the famous question concerning literary property, which the majority of the judges of the court of King's Bench held to be permanent: and in support of which opinion, such arguments were urged by the chief justice, as have not yet perhaps been completely answered.

The ill success of the war, which had lately been begun, occasioned a change in the administration; and the conflicts of contending parties rendered it impracticable for the crown, at that juncture, to settle a new ministry. In order, therefore, to give pause to the violence of both sides, Lord Mansfield was induced to accept the post of chancellor of the exchequer on the 9th of April 1757; which he held until the 2d of July in the same year. During this interval, he employed himself, with great success, to bring about a coalition; which being effected, produced a series of events, which raised the glory of Great Britain to the highest point at which it has ever been seen. In the same year he was offered, but refused, the office of Lord High Chancellor; and in November 1758, he was elected a governor of the charter house, in the room of the Duke of Marlborough, then lately deceased.

For several years after this period, the tenor of Lord Mansfield's life was marked only with a most sedulous discharge of the duties of his office. In 1760 Geo. II. died, and the new reign commenced with alterations in the administration; which gave rise to a virulent spirit of opposition, conducted with a degree of violence and asperity never known at any former time. As a friend to the then administration, Lord Mansfield was marked out for a more than ordinary share of malicious invective. It is in allusion to this, that Warburton, after tracing the rise and progress of the irreligion and licentiousness which then prevailed, and observing that, amid such general corruption, the pure administration of public justice still afforded a cheerful consolation to thinking men, proceeds thus:

"But the evil genius of England would not suffer us to enjoy it long; for, as if envious of this last support of government, he hath now instigated his blackest agents to every extent of their malignity; who, after the most villainous insults on all other orders and ranks in society, have at length proceeded to calumniate even the king's supreme court of justice, under its ablest and most unblemished administration. After this, who will not be tempted to despair of his country, and say with the good old man in the scene,

——"*Ipsa si cupiat salus*
"*Servare, prorsus non potest, hanc Familiam* (D)?"

Murray. A change of administration again took place in 1765 which introduced the Marquis of Rockingham and his friends to govern the country; and the measures then adopted not agreeing with Lord Mansfield's sentiments, he, for the first time, became an opponent of government. On the bill for repealing the stamp act, he spoke, and divided against it; and is supposed to have had some share in the composition of the protests on that occasion, though he did not sign them. In the same year, he is said to have animadverted, with no small degree of severity, on the incautious expressions of Lord Camden, on the affair of prohibiting the exportation of corn, that it was but a 40 days tyranny at the outside (E).

In 1767, the Dissenters cause was determined, in which Lord Mansfield delivered a speech, which has since been printed, and shews his Lordship to have been a steady friend to religious toleration, as well as to the rights of the established church. The conscientious Dissenters themselves lavished upon that speech the highest praise; whilst others of them, in the succeeding year, deluged the public prints with torrents of abuse on the Chief Justice. In that year was the general election. Mr Wilkes returned from abroad, became a candidate for the city of London, and afterwards was chosen representative for the county of Middlesex. Having been outlawed some years before, he now applied for a reversal of that proceeding. On the 8th of June, the consideration of it came before the court of King's Bench; when the judges delivered their opinions very fully, and were unanimous that the outlawry was illegal, and must be reversed. On this occasion, Lord Mansfield took the opportunity of entering into a full statement of the case, and a justification of his own conduct. The reader will find the case reported by Sir James Burrow, from whom we shall extract the following, which appears to have been the most important part of his Lordship's speech:

"It is fit to take some notice of the various terrors hung out; the numerous crowds which have attended, and now attend, in and about the hall, out of all reach of hearing what passes in court; and the tumults which in other places have shamefully insulted all order and government. Audacious addresses in print dictate to us, from those they call the people, the judgment to be given now, and afterwards upon the conviction. Reasons of policy are urged, from danger to the kingdom, by commotions and general confusion.

"Give me leave to take the opportunity of this great and respectable audience, to let the whole world know all such attempts are vain. Unless we have been able to find an error which will bear us out to reverse the outlawry, it must be affirmed. The constitution does not allow reasons of state to influence our judgment: God

(D) See the dedication of the 5th edition of the Divine Legation of Moses, which deserves to be read at present with peculiar attention, as the work of a man of gigantic talents, deeply read in law as well as in theology.

(E) The speeches in the debate were never printed; but the substance of them all was consolidated in a pamphlet published at the time, intituled, "A Speech against the suspending and dispensing prerogative," 8vo. Since reprinted in Debrett's Debates, Vol IV. p. 3[illegible]4.

Murray. God forbid it should! We must not regard political consequences, how formidable soever they may be; we are bound to say, *Fiat Justitia, ruat Cælum*. The constitution trusts the king with reasons of state and policy: He may pardon offences; it is his to judge whether the law or the criminal should yield. We have no election. None of us encouraged or approved the commission of either of the crimes of which the defender is convicted: none of us had any hand in his being prosecuted. As to myself, I took no part (in another place) in the addresses for that prosecution. We did not advise or assist the defender to fly from justice; it was his own act, and he must take the consequences. None of us have been consulted, or had any thing to do with the present prosecution. It is not in our power to stop it; it was not in our power to bring it on. We cannot pardon. We are to say what we take the law to be. If we do not speak our real opinions, we prevaricate with God and our own consciences.

"I pass over many anonymous letters I have received: those in print are public; and some of them have been brought judicially before the court. Whoever the writers are, they take the wrong way. I will do my duty unawed. What am I to fear? That *mendax infamia* from the press, which daily coins false facts and false motives? The lies of calumny carry no terror to me. I trust, that my temper of mind, and the colour and conduct of my life, have given me a suit of armour against these arrows. If, during this king's reign, I have ever supported his government, and assisted his measures, I have done it without any other reward than the consciousness of doing what I thought right. If I have ever opposed, I have done it upon the points themselves, without any collateral views. I honour the king, and respect the people. But many things acquired by the favour of either are, in my account, objects not worth ambition. I wish popularity; but it is that popularity which follows, not that which is run after.—It is that popularity which, sooner or later, never fails to do justice to the pursuit of noble ends by noble means. I will not do that which my conscience tells me is wrong upon this occasion, to gain the huzzas of thousands, or the daily praise of all the papers which come from the press. I will not avoid doing what I think is right, though it should draw on me the whole artillery of libels, all that falsehood and malice can invent, or the credulity of a deluded populace can swallow. I can say with a great magistrate, upon an occasion, and under circumstances not unlike, '*Ego hoc animo semper fui, ut invidiam virtute partam, gloriam, non invidiam putarem.*'

"The threats go further than abuse: Personal violence is denounced. I do not believe it: it is not the genius of the worst men of this country in the worst of times. But I have set my mind at rest. The last end that can happen to any man never comes too soon, if he falls in support of the law and liberty of his country (for liberty is synonymous to law and government). Such a shock, too, must be productive of public good: It might awake the better part of the kingdom out of that lethargy which seems to have benumbed them; and bring the mad part back to their senses, as men intoxicated are sometimes stunned into sobriety.

"Once for all, let it be understood, that no endeavours of this kind will influence any man who at present sits here. If they had any effect, it would be contrary to their intent: Leaning against their impression might give a bias the other way. But I hope, and I know, that I have fortitude enough to resist even that weakness. No libels, no threats, nothing that has happened, nothing that can happen, will weigh a feather against allowing the defendant, upon this and every other question, not only the whole advantage he is intitled to from substantial law and justice, but every benefit from the most critical nicety of form, which any other defender could claim under the like objection. The only effect I feel is an anxiety to be able to explain the grounds upon which we proceed; so as to satisfy all mankind, that a flaw of form given way to in this case, could not have been got over in any other."

In January 1770, Lord Mansfield again was offered the Great Seal, which was given to Mr Charles York: and in Hilary Term 1771, he a third time declined the same offer, and the Seal was entrusted to Lord Bathurst.

The year 1770 was also memorable for various attacks made on his Lordship's judicial character, in both the Houses of Lords and Commons. In one of these, the propriety of a direction given to the jury in the case of the king and Woodfal was called in question; which occasioned his Lordship to produce to the House a copy of the unanimous opinion of the court of King's Bench in that cause; which, after being much canvassed and opposed, was suffered to stand its ground without being over-ruled.

On the 19th of October 1776, his Lordship was advanced to the dignity of an Earl of Great Britain, by the title of the Earl of Mansfield, and to his male issue; and for want of such issue, to Louisa Viscountess Stormont, and to her heirs male by David Viscount Stormont her husband. The same title, in 1792, was limited to Lord Stormont himself; who afterwards succeeded to it.

We come now to a period of his Lordship's life, which furnishes an event disgraceful to the age and country in which the fact was committed. An union of folly, enthusiasm, and knavery, had excited alarms in the minds of some weak people, that encouragements were given to the favourers and professors of the Roman Catholic faith inconsistent with religion and true policy. The act of Parliament, which excited the clamour, had passed with little opposition, and had not received any extraordinary support from Lord Mansfield. The minds of the public were inflamed by artful misrepresentations; the rage of a popular mob was soon directed towards the most eminent persons. Accordingly, in the night between Tuesday the 6th and Wednesday the 7th of June 1780, his Lordship's house in Bloomsbury Square was attacked by a party of rioters, who, on the Friday and Tuesday preceding, had, to the amount of many thousands, surrounded the avenues of both Houses of Parliament, under pretence of attending Lord George Gordon when he presented the petition from the Protestant Association. On Tuesday evening the prison of Newgate had been thrown open, all the combustible part reduced to ashes, and the felons let loose upon the public. It was after this attempt to destroy the means of securing the victims of criminal justice that the rioters assaulted the residence of the chief magistrate of the first criminal court in the kingdom; nor were they dispersed till they had burnt all the furniture, pictures books, manuscripts, deeds, and, in short, every thing which fire could consume in his Lordship's

Murray. ship's house; so that nothing remained but the walls, which were seen next morning almost red-hot from the violence of the flames, presenting a melancholy and awful ruin to the eyes of the passengers. For a fuller account of those dreadful riots, see BRITAIN, n° 644. *Encyclopædia*.

So unexpected was this daring outrage on order and government, that it burst on Lord Mansfield without his being prepared in the slightest manner to resist it. He escaped with his life only, and retired to a place of safety, where he remained until the 14th of June, the last day of term, when he again took his seat in the court of King's Bench. "The reverential silence (says Mr Douglas) which was observed when his Lordship resumed his place on the Bench, was expressive of sentiments of condolence and respect, more affecting than the most eloquent address the occasion could have suggested.

"The amount of that part of Lord Mansfield's loss which might have been estimated, and was capable of a compensation in money, is known to have been very great. This he had a right to recover against the *hundred*. Many others had taken that course; but his Lordship thought it more consistent with the dignity of his character not to resort to the indemnification provided by the legislature. His sentiments, on the subject of a reparation from the state, were communicated to the Board of Works in a letter, dated 18th July 1780, written in consequence of an application which they had made to him (as one of the principal sufferers), pursuant to directions from the treasury, founded on a vote of the House of Commons, requesting him to state the nature and amount of his loss. In that letter, after some introductory expressions of civility to the surveyor general, to whom it was addressed, his Lordship says, 'Besides what is irreparable, my pecuniary loss is great. I apprehended no danger, and therefore took no precaution. But how great soever that loss may be, I think it does not become me to claim or expect reparation from the state. I have made up my mind to my misfortune, as I ought, with this consolation, that it came from those whose object manifestly was general confusion and destruction at home, in addition to a dangerous and complicated war abroad. If I should lay before you any account or computation of the pecuniary damage I have sustained, it might seem a claim or expectation of being indemnified. Therefore you will have no further trouble upon this from, &c.—*Mansfield*."

From this time the lustre of Lord Mansfield continued to shine with unclouded brightness until the end of his political life, unless his opposition to the measures of the present administration, at the early period of their appointment, shall be thought to detract, in some small degree, from his merit. It is certain many of his admirers saw, with concern, a connection with the opponents of government at that juncture, scarce compatible with the dignity of the chief justice of Great Britain. At length infirmities pressed upon him, and he became unable to attend his duty with the same punctuality and assiduity with which he had been accustomed. It has been supposed, that he held his office after he was disabled from executing the duties of it, from a wish to secure the succession of it to a very particular friend. Be this as it may, the chief justice continued in his office until the month of June 1788, when he sent in his resignation.

From this period the bodily powers of his Lordship continued to decline; his mental faculties, however, remained without decay almost to the last. During this time he was particularly inquisitive and anxious about the proceedings in France, and felt his sensibility, in common with every good man, wounded by the horrible instance of democratic infatuation in the murder of the innocent Louis XVI. He lived just long enough to express his satisfaction at the check given to the French by the Prince of Cobourg in March 1793; on the 20th of which month, after continuing some days in a state of insensibility, he departed this life, at the age of 88 years.

"In his political oratory (says a writer of the present times), he was not without a rival; no one had the honour of *surpassing* him; and let it be remembered, that his competitor was PITT.

"The rhetorician that addressed himself to Tully in these memorable words—*Demosthenes tibi præripuit ne primus esses Orator, tu illi ne solus*—anticipated their application to Mansfield and Pitt. If the one possessed Demosthenean fire and energy, the other was at least a Cicero. Their oratory differed in species, but was equal in merit. There was, at least, no superiority on the side of Pitt. Mansfield's eloquence was not, indeed, of that daring, bold, declamatory kind, so irresistibly powerful in the momentary bustle of popular assemblies; but it was possessed of that pure and Attic spirit, and seductive power of persuasion, that delights, instructs, and eventually triumphs. It has been very beautifully and justly compared to a river, that meanders through verdant meads and flowery gardens, reflecting in its crystal bosom the varied objects that adorn its banks, and refreshing the country through which it flows.

"To illustrate his oratory by example, would require voluminous transcripts from the records of Parliament; and it is unnecessary, as we can appeal to living recollection.

"Having added weight and dignity to the offices of attorney and solicitor general, his reputation as a speaker, a lawyer, and a politician, elevated him to the peerage, and the exalted post of chief justice of England. He ascended to the dignities of state by rapid strides: they were not bestowed by the caprice of party favour or affection. They were (as was said of Pliny) liberal dispensations of power upon an object that knew how to add new lustre to that power, by the rational exertion of his own.

"Here we can speak of this great man within our own recollection; and however party prejudices may adopt their different favourites, and each contend in detracting from the merit of the other, it is, we believe, generally understood, that precedence is allowed the Earl of Mansfield, as the first magistrate that ever so pre-eminently graced that important station. The wisdom of his decisions, and unbiassed tenor of his public conduct, will be held in veneration by the sages of the law, as long as the spirit of the constitution, and just notions of equity, continue to have existence. No man has ever, in an equal degree, possessed that wonderful sagacity in discovering chicanery and artifice, and separating fallacy from truth, and sophistry from argument, so as to hit the exact equity of the case. He suffered not justice to be strangled in the nets of form.

"His memory was astonishing—he never took notes, or,

or, if he did, seldom or ever consulted them." His references to expressions which fell from him in the course of the debate, or his quotations from books, were so faithful, that they might have been said to have been repeated *verbatim*. The purposes to which he employed these amazing talents were still more extraordinary: if it was the weak part of his opponent's arguments that he referred to, he was sure to expose its fallacy, weakness, or absurdity, in the most poignant satire, or hold it up in the most ridiculous point of view. If, on the contrary, it were a point on which his adversaries laid their chief stress, he stated the words correctly; collected their obvious meaning, considered the force of the several arguments that had or might have been raised upon them, with a precision that would induce an auditor almost to suppose that he had previously considered the whole, and that his speech was the result of much previous study.

"It may be said of Mansfield as of Virgil, that if he had any faults, they might be considered in the same manner with those of some eminent fixed star, which, if they exist at all, are above the reach of human observation. The luminous æther of his life was not obscured by any shade dark enough to be denominated a defect. On account of his descent, local prejudices and propensities were imputed to him, and his conduct, on that account, examined with a microscopic eye; but the optic through which it was viewed possessed a party tinge, equally odious and deceptive.

"His political principles were ever consistent; and to preserve consistency in such stations and in such times as occupied the life of Mansfield, constitutes an ordeal strongly impressive of virtue. It has been said that he wanted spirit. Is the uniform opposition of popular opinion, and apparently the contempt of it, any proof of the assertion? His speech and conduct in the affair of Wilkes's outlawry, when popular prejudice ran in torrents, illustrate each other. He despised (to borrow an expression of his own) that mushroom popularity that is raised without merit, and lost without a crime. He disdained being the slave of popular impulse, or to acknowledge the shouts of a mob for the trumpet of fame."

He had a mind too great to be ashamed of revering the ordinances of religion; and as, after the most impartial inquiry, he was a firm believer of the truth and importance of Christianity, he frequented the church regularly, and received the holy sacrament on the higher festivals. Mr Holliday has published a sermon, which he says was dictated by Lord Mansfield to his friend bishop Johnson, and preached by that prelate before the House of Lords. It is a very serious and appropriate discourse; but judging upon internal evidence, we should not have supposed it the composition of the eloquent and argumentative chief justice of England. His Lordship's will, which was written with his own hand, upon little more than half a sheet of paper, begins with the following elegant and pious paragraph, with which we shall conclude this sketch of his character:

"When it shall please Almighty God to call me to that state, to which, of all I now enjoy I can carry only the satisfaction of my own conscience, and a full reliance upon his mercy through Jesus Christ, I desire that my body may be interred as privately as may be: and out of respect for the place of my early education, I should wish it to be in Westminster Abbey." It was interred in Westminster Abbey, in the same vault with the Countess (who had died April 10. 1784), between the late Earl of Chatham and Lord Robert Manners.

Museum.

MUSEUM, in the language of the present day, is a building in which are deposited specimens of every object that is in any degree curious, whether such objects be natural or artificial. What the word *museum* expressed originally, has been told under that title in the *Encyclopædia*.

A complete museum contains collections of preserved beasts, birds, fishes, reptiles, &c.; models of machines; rare manuscripts; and indeed specimens of every thing necessary to illustrate physical science, to improve art, to aid the antiquarian in his researches, and to exhibit the manners and customs of men in distant ages and nations. As natural objects of uncommon size or beauty, and other rare productions, were, in the earliest periods, consecrated to the gods, the temples were, of course, the first repositories of such collections, or, in other words, the first *Museums*. This, we think, has been completely proved by Professor Beckmann *.

"When Hanno (says he) returned from his distant voyages, he brought with him to Carthage two skins of the hairy women whom he found on the Gorgades islands, and deposited them as a memorial in the temple of Juno, where they continued till the destruction of the city. The horns of a Scythian animal, in which the Stygian water that destroyed every other vessel could be contained, were sent by Alexander as a curiosity to the temple of Delphi, where they were suspended, with an inscription, which has been preserved by Ælian. The monstrous horns of the wild bulls which had occasioned so much devastation in Macedonia, were, by order of King Philip, hung up in the temple of Hercules. The unnaturally formed shoulder bones of Pelops were deposited in the temple of Elis. The horns of the so called Indian ants were shewn in the temple of Hercules at Erythræ; and the crocodile found in attempting to discover the sources of the Nile was preserved in the temple of Isis at Cæsarea. A large piece of the root of the cinnamon tree was kept in a golden vessel in one of the temples at Rome, where it was examined by Pliny. The skin of that monster which the Roman army in Africa attacked and destroyed, and which probably was a crocodile, an animal common in that country, but never seen by the Romans before the Punic war, was, by Regulus, sent to Rome, and hung up in one of the temples, where it remained till the time of the Numantine war (A). In the temple of Juno, in the island of Melita, there were a pair of elephants teeth of extraordinary size, which were carried away by Masinissa's admiral, and transmitted to that prince, who, though he set a high value upon them, sent them again back, because he heard they had been taken from a temple. The head of a basilisc was exhibited in one of the temples of Diana; and the bones of that sea monster, probably a whale, to which Andromeda was exposed, were preserved at Joppa, and afterwards brought to Rome.

* Vol. iv. p. 44.

(A) We think, with the translator of Beckmann's History, that this animal was not the crocodile, but the *Boa constrictor*. See Boa and Serpent, *Encycl.*

Rome. In the time of Paufanias, the head of the celebrated Calydonian boar was fhewn in one of the temples of Greece; but it was then deftitute of briftles, and had fuffered confiderably by the hand of time. The monftrous tufks of this animal were brought to Rome, after the defeat of Anthony, by the Emperor Auguftus, who caufed them to be fufpended in the temple of Bacchus. Apollonius tells us, that he faw in India fome of thofe nuts which in Greece were preferved in the temples as curiofities."

Though thefe curiofities were preferved in the temples for purpofes very different from thofe for which our collections are made, there can be no doubt but that they contributed to promote the knowledge of natural hiftory. If it be true, as Pliny and Strabo inform us, that Hippocrates availed himfelf of the accounts which were hung up in the temple of Æfculapius of different difeafes, and of the medicines and mode of treatment by which they were cured; it will eafily be believed, that the natural hiftorians availed themfelves, in a fimilar manner, of the various rare objects which were preferved in the temples of the other gods. This, we fee, Pliny actually did.

Suetonius informs us, that Auguftus had, in his palace, a collection of natural curiofities; and it is well known that Alexander gave orders to all huntfmen, bird catchers, fifhermen, and others, to fend to Ariftotle whatever rare animals they could procure. M. Beckmann feems to be of opinion, that the firft private mufeum was formed by Apuleius, who, next to Ariftotle and his fcholar Theophraftus, certainly examined natural objects with the greateft ardour and judgment; who caufed animals of every kind, and particularly fifh, to be brought to him either dead or alive, in order to defcribe their external and internal parts, their number and fituation, and to determine their characterifing marks, and eftablifh their real names; who undertook diftant journeys to become acquainted with the fecrets of nature; and who, on the Getulian mountains, collected petrefactions, which he confidered as the effects of Deucalion's flood.

The principal caufe why collections of natural curiofities were fcarce in ancient times, muft have been the ignorance of naturalifts in regard to the proper means of preferving fuch bodies as foon fpoil or corrupt. Some methods were indeed known and practifed, but they were all defective and inferior to that by fpirit of wine, which prevents putrefaction, and which, by its perfect tranfparency, permits the objects which are covered by it to be at all times viewed and examined. Thefe methods were the fame as thofe employed to preferve provifions, or the bodies of great men deceafed. They were put into falt brine or honey, or were covered over with wax. Thus the hippopotamus, defcribed by Columna, was fent to him from Egypt preferved in falt. The body of Agefipolis King of Sparta, who died in Macedonia, was fent home in honey; the celebrated purple dye of the ancients was preferved frefh for many years by the fame means; and at this day, when the Orientals are defirous of tranfporting fifh to any diftance, they cover them over with wax.

In thofe centuries which are ufually called the middle ages, the Profeffor finds no traces of what can be called a mufeum, except in the treafuries of emperors, kings, and princes, where, befides articles of great value, curiofities of art, antiquities, and relics, one fometimes found fcarce and fingular foreign animals, which were dried and preferved. Such objects were to be feen in the old treafury at Vienna; and in that of St Denis was exhibited the claw of a griffin, fent by a king of Perfia to Charlemagne; the teeth of the hippopotamus, and other things of the like kind. In thefe collections, the number of the rarities always increafed in proportion as a tafte for natural hiftory became more prevalent, and as the extenfion of commerce afforded better opportunities for procuring the productions of remote countries. Menageries were eftablifhed to add to the magnificence of courts, and the ftuffed fkins of rare animals were hung up as memorials of their having exifted. Public libraries alfo were made receptacles for fuch natural curiofities as were from time to time prefented to them; and as in univerfities the faculty of medicine had a hall appropriated for the diffection of human bodies, curiofities from the animal kingdom were collected there alfo by degrees; and it is probable that the profeffors of anatomy firft made attempts to preferve different parts of animals in fpirit of wine, as they were obliged to keep them by them for the ufe of their fcholars; and becaufe in old times dead bodies were not given up to them as at prefent, and were more difficult to be obtained. Private collections appear for the firft time in the 16th century; and there is no doubt (fays our author) that they were formed by every learned man who at that period applied to the ftudy of natural hiftory.

MUSHROOM, a fungus, of which fome of the principal fpecies have been defcribed in the *Encyclopædia* under the generic name AGARICUS. There is, however, one fpecies not mentioned there—the *Boletus hirfutus* of Bulliard, which is certainly worthy of notice, fince one of the French chemifts has lately extracted from it a bright, fhining, and very durable yellow dye. This pretty large mufhroom grows commonly on walnut and apple-trees. Its colouring-matter is contained in abundance, not only in the tubular part, but alfo in the parenchyma of the body of the mufhroom. In order to extract it, the mufhroom is pounded in a mortar, and the liquor thence obtained is boiled for a quarter of an hour in water. An ounce of liquor is fufficient to communicate colouring-matter to fix pounds of water. When the liquor has been ftrained, the ftuff to be dyed is put into it, and boiled for a quarter of an hour. All kinds of ftuff receive this colour and retain it; but on linen and cotton it is lefs bright. This colour may be modified, in a very agreeable manner, by the effect of mordants.

The procefs fucceeded beft on filk. When this fubftance, after being dyed, is made to pafs through a bath of foft foap, it acquires a fhining golden yellow colour, which has a perfect refemblance to the yellow of that filk employed to imitate embroidery in gold, and which has hitherto been brought from China and fold at a dear rate, as the method of dyeing it is unknown in Europe. The yellow colour extracted from this mufhroom may be employed alfo with advantage for painting in water colours as well as in oil.

MUTSUDDIES, in Bengal, writers, accountants, officers of government.

MUZCOORET, allowances to zemindars in land or money. See ZEMINDAR, *Suppl.*

NABOB,

N.

NABOB, or Nowab, a title of courteſy given in India to Mahomedans high in ſtation, particularly provincial governors.

The Sun's NADIR, is the axis of the cone projected by the ſhadow of the earth: ſo called, becauſe that axis being prolonged, gives a point in the ecliptic diametrically oppoſite to the ſun.

NAIB, a deputy.

NAKED, in architecture, as the naked of a wall, &c. is the ſurface, or plane, from whence the projectures ariſe; or which ſerves as a ground to the projectures.

NANCOWRY, or Soury, as it is ſometimes called, is one of the Nicobar iſles, and ſituated nearly in the centre of the cluſter (See Nicobar, *Encycl.*). Its length may be about eight miles, and its breadth nearly equal. The iſland of Comerty, which is near it, is more extenſive, but does not perhaps contain more ſolid land, being excavated by a very large bay from the ſea. The ſpace between theſe two iſlands forms a capacious and excellent harbour, the eaſtern entrance of which is ſheltered by another iſland, called Trikut, lying at the diſtance of about a league. The inlet from the weſt is narrow, but ſufficiently deep to admit the largeſt ſhips when the wind is fair.

The Danes have long maintained a ſmall ſettlement at this place, which ſtands on the northern-moſt point of Nancowry, within the harbour. A ſerjeant and three or four ſoldiers, a few black ſlaves, and two ruſty old pieces of ordnance, compoſe the whole of their eſtabliſhment. They have here two houſes; one of which, built entirely of wood, is their habitation; the other, formerly inhabited by their miſſionaries, ſerves now for a ſtorehouſe.

Theſe iſlands are in general woody, but contain likewiſe ſome portions of clear land. From the ſummits of their hills the proſpects are often beautiful and romantic. The ſoil is rich, and probably capable of producing all the various fruits and vegetables common to hot climates. The natural productions of this kind, which moſtly abound, are cocoa nuts, *papias*, plantains, limes, tamarinds, beetle-nuts, and the *melöri*, a ſpecies of breadfruit; yams, and other roots are cultivated and thrive; but rice is here unknown. The *mangoſtain*-tree, whoſe fruit is ſo juſtly extolled, grows wild; and pine-apples of a delicious flavour are found in the woods.

Of all the Nicobar iſles Nancowry and Comerty are ſaid to be the beſt peopled; the population of both being ſuppoſed to amount to eight hundred. The natives of Nancowry and of the Nicobar iſlands in general, live in villages on the ſea-ſhore, and never erect their habitations inland (A). Their houſes are of a circular form, and are covered with elliptical domes, thatched with graſs and the leaves of cocoa nut. They are raiſed upon piles to the height of ſix or eight feet above the ground; the floor and ſides are laid with planks, and the aſcent is by a ladder. In thoſe bays or inlets which are ſheltered from the ſurf, they erect them ſometimes ſo near the margin of the water as to admit the tide to flow under, and waſh away the ordure from below.

In front of their villages, and a little advanced in the water, they plant beacons of a great height, which they adorn with tufts made of graſs, or the bark of ſome tree. Theſe objects are diſcernible at a great diſtance, and are intended probably for landmarks; their houſes, which are overſhadowed by thick groves of cocoa nut trees, ſeldom being viſible from afar.

The Nicobareans, though indolent, are in general robuſt and well-limbed. Their features are ſomewhat like the Malays, and their colour is nearly ſimilar. The women are much inferior in ſtature to the men, but more active in all domeſtic affairs. Contrary to the cuſtom of other nations, the women ſhave the hair of their heads, or keep it cloſe cropt, which gives them an uncouth appearance, in the eyes of ſtrangers at leaſt.

The inhabitants of Nancowry perform, every year, a very extraordinary ceremony in honour of the dead. It is thus deſcribed by Lieutenant Colebrooke:

"On the anniverſary of this feſtival, if it can be ſo called, their houſes are decorated with garlands of flowers, fruits, and branches of trees. The people of each village aſſemble, dreſt in their beſt attire, at the principal houſe in the place, where they ſpend the day in a convivial manner; the men, ſitting apart from the women, ſmoke tobacco, and intoxicate themſelves; while the latter are nurſing their children, and employed in preparations for the mournful buſineſs of the night. At a certain hour of the afternoon, announced by ſtriking the *Goung*, the women ſet up the moſt diſmal howls and lamentations, which they continue without intermiſſion till about ſun-ſet; when the whole party get up, and walk in proceſſion to the burying-ground. Arrived at the place, they form a circle around one of the graves, when a ſtake, planted exactly over the head of the corpſe, is pulled up. The woman who is neareſt of kin to the deceaſed, ſteps out from the crowd, digs up the ſkull, and draws it up with her hands. At ſight of the bones, her ſtrength ſeems to fail her; ſhe ſhrieks, ſhe ſobs; and tears of anguiſh abundantly fall on the mouldering object of her pious care. She clears it from the earth, ſcrapes off the feſtering fleſh, and laves it plentifully with the milk of freſh cocoa-nuts, ſupplied by the byſtanders; after which ſhe rubs it over with an infuſion of ſaffron, and wraps it carefully in a piece of new cloth. It is then depoſited again in the earth, and covered up; the ſtake is replanted, and hung with the various trappings and imple-

(A) The great Nicobar iſland is perhaps an exception, where, it is ſaid, a race of men exiſts, who are totally different in their colour and manners. They are conſidered as the *Aborigines* of the country. They live in the interior parts among the mountains, and commit frequent depredations on the peaceable inhabitants of the coaſts.

implements belonging to the deceased. They proceed then to the other graves; and the whole night is spent in repetitions of these dismal and disgustful rites.'

"On the morning following, the ceremony is concluded by an offering of many fat swine; when the sacrifice made to the dead affords an ample feast to the living: they besmear themselves with the blood of the slaughtered hogs, and some, more voracious than others, eat the flesh raw. They have various ways, however, of dressing their meat, but always eat it without salt. A kind of paste made of the *melóri*, serves them for bread; and they finish their repast with copious potations of *taury*, an inebriating liquor."

The Nicobareans are hospitable and honest, and are remarkable for a strict observance of truth, and for punctuality in adhering to their engagements. Such crimes as theft, robbery, and murder, are unknown in these islands; but they do not want spirit to revenge their injuries, and will fight resolutely, and slay their enemies, if attacked or unjustly dealt with. Their only vice, if this failing can be so called, is inebriation; but in their cups they are generally jovial and good-humoured. It sometimes, however, happens at their feasts, that the men of different villages fall out; and the quarrel immediately becomes general. In these cases they terminate their differences in a pitched battle; where the only weapons used are long sticks, of a hard and knotty wood. With these they drub one another most heartily, till, no longer able to endure the conflict, they mutually put a stop to the combat, and all get drunk again.

NANKAR, ancient allowance to zemindars in land or money.

NANKEEN, or NAN-KING, is a well-known cotton stuff, which derives its name from the ancient capital of China (See NAN-KING, *Encycl.*). It is, however, according to Van Braam, manufactured at a great distance from that city, in the district of *Fong-kiang-fou*, situated in the south-east of the province of *Kiang-nam* upon the sea-shore. The colour of nankeen is natural, the down of which it is made being of the same yellow tinge with the cloth. The colour, as well as superior quality of this cotton, seems to be derived from the soil; for it is said that the seeds of the nankeen cotton degenerate in both particulars when transplanted to another province, however little different in its climate. The common opinion, that the colour of the stuff is given by a dye, occasioned an order from Europe, some years ago, to dye the pieces of nankeen of a deeper colour than they had at that period; and the reason of their being then paler than formerly is as follows:

Shortly after the Americans began to trade with China, the demand increased to nearly double the quantity it was possible to furnish. To supply this deficiency, the manufacturers mixed common white cotton with the brown; this gave it a pale cast, which was immediately remarked; and for this lighter kind no purchaser could be found, till the other was exhausted. As the consumption is grown less during the last three years, the mixture of cotton is no longer necessary, and nankeen is become what it was before. By keeping them two or three years, it even appears that they have the property of growing darker. This kind of stuff must be acknowledged to be the strongest yet known. Many persons have found that clothes made of it will last three or four years, although for ever in the wash. This it is that makes them the favourite wear for breeches and waistcoats both in Europe and America. The white nankeen is of the same quality, and is made of white cotton as good as the brown, and which also grows in Kiang nam.

NAPLES-YELLOW, called also *Neapolitan earth*, in Italian *Giallolino*, and in French *Jaune de Naples*, is a beautiful pigment, concerning which we have much information from the indefatigable Beckmann. "It has (says he) the appearance of an earth, is of a pale orange-yellow colour, ponderous, granulated, exceedingly friable, does not effloresce, nor become moist when exposed to the air, but when applied to the tongue seems to adhere to it. When reduced to a fine powder, it remains for some time suspended in water, but soon deposits itself at the bottom in the form of a slime. When boiled with water, the water, at least sometimes, is served to have a somewhat saline taste. It does not effervesce with acids, but is in part dissolved by aqua regia (nitro-muriatic acid). In the fire it emits no sulphureous vapour, is difficult to be fused, and by that operation undergoes no material change, only that its colour becomes somewhat redder. When fused with colourless glass, it gives it a milk-white colour, a sure proof that it contains no iron; and, with inflammable substances, there is obtained from it a regulus which has the appearance of a mixture of lead and antimony.

"This article is brought from Naples for the most part in the form of an earthy crust about three or four lines in thickness, and it sometimes retains the form of the vessel in which it has hardened. It can be procured also as a fine powder, as the colourmen keep it sometimes ready pounded for use."

About the nature of the substance called Naples yellow there has been much diversity of opinion. Most of those who have written about it, consider it as originating from fire, and as a volcanic production of Mount Vesuvius or Mount Ætna; others have pronounced it to be a natural ochre. Guettard thought it rather a kind of bole; but Pott approached nearest the truth, by asserting it to be an artificial preparation *. Fougeroux is entitled to the merit of having proved this, and of having shewn the possibility of preparing it. According to his experiments, Naples yellow will be obtained, if you boil for seven or eight hours, first over a slow and then over a strong fire, a mixture finely pulverised of twelve parts of pure white lead, one part of alum, one part of sal ammoniac, and three parts of diaphoretic antimony † (white oxyd of antimony by nitre). But before Fougeroux, who may have obtained an account of the process during his travels through Italy, a more certain process was published in the year 1758, by Giambattista Passeri, in his interesting work on the painting of earthen ware ‡. The articles to be employed, according to this author, are, "one pound of antimony, a pound and a half of lead, one ounce of *alume di feccia*, and the same quantity of common salt." I am inclined (says M. Beckmann) to think that this receipt was not unknown to Fougeroux, and that he considered *alume di feccia* to be alum. Professor Leonhardi, a man of very sound learning, has translated this expression by the word alum. I will, however, freely confess, that I consider *alume di feccia* not to mean alum, but salt of tartar, or potash. Pas-

* *Lithogeognosie*, v. ii. p. 15.

† *Mem. of the Acad. of Sciences*, 1766.

‡ *In Nuova raccolta di opusculi scientifici*, iv.

Naples, Nardus.

feri says, that the proportions may be varied different ways; and he gives six other receipts, in which he does not mention *alume di feccia*, but only *feccia*; and this word certainly means *weinhefen* or winestone (tartar). Professor Leonhardi himself seems to confirm this opinion, by saying, that Vairo, professor of chemistry at Naples, has translated "the ashes of wine lees" (*cineres infectorii*) by the words *alume di feccia*.

After Fougeroux's paper was printed, De la Lande published a receipt which he had received from the well-known prince San Severo, and in which lead and antimony only are employed; but no mention is made either of alum, tartar, or any other salt. This receipt is as follows:

Take lead well calcined and sifted, with a third part of its weight of antimony pounded and sifted also. Mix these substances well together, and sift them again through a piece of silk. Then take large flat earthen dishes, not varnished, cover them with white paper, and spread out the powder upon them to the depth of about two inches. Place these dishes in a potter's furnace, but only at the top, that they may not be exposed to too violent a heat. The reverberation of the flame will be sufficient. The dishes may be taken out at the same time as the earthen-ware, and the substance will then be found hard, and of a yellow colour. It is then pounded on a piece of marble with water, and afterwards dried for use.

The enamel-painters in Germany prepare a yellow glazing, not very different from the real Naples yellow, by a prescription, according to which, "one pound of antimony, six ounces of red lead, and two ounces of white sand, are to be fused together. The produce, which appears quite black, is to be pounded, and then fused again; and this process is to be repeated till the whole mass becomes thoroughly yellow. Half a pound of this mass is to be mixed with two ounces of red lead, and afterwards fused; and by this tedious process an orange-yellow pigment will be obtained."

All artists who speak of the use of Naples yellow, give cautions against applying iron to it, as the colour by these means becomes greenish, or at least dirty. For this reason, it must be pounded on a stone, and scraped together with an ivory spatula. It is employed chiefly in oil painting, because the colour is softer, brighter, and richer than that of ochre, yellow lead, or orpiment, and because it far exceeds these pigments in durability. It is employed in particular when the yellow ought to have the appearance of gold, and in this respect it may be prepared with gum water, and used as a water colour. A still greater advantage of it is, that it is proper for enamel painting, and on that account may be employed on porcelain or earthen ware (A). Professor Beckmann, however, recommends to artists to examine whether the oxyd prepared from wolfram, by boiling in the muriatic acid, which has a beautiful yellow colour, might not be used in the same manner as Naples yellow.

NARDUS. Under this generic term we have, in the *Encyclopædia*, given, from the *Philosophical Transactions*, a description of the plant or grass which Dr Blane considers as the spikenard of the ancients. It is our duty, in this place, to inform our readers, that Sir William Jones, in the 2d and 4th volumes of the *Asiatic Researches*, seems to have completely proved that the spikenard of Dioscorides and Galen, or *Nardus Indica*, was a very different plant from the Andropogon of Dr Blane, and that it grows in a country far distant from *Mackran*. The proofs brought by the illustrious president of the Asiatic Society, in support of his own opinion, are too numerous and circumstantial to be introduced into such a work as this. We shall therefore only give one of them; which though, when separated from the rest, it loses much of its force, must be allowed, even singly, to have great weight.

Nar Na

The true Indian spikenard is confessedly called by the Arabs *Sumbulu'l Hind*; for so they translate the name of it in Dioscorides. Now (says Sir William) I put a fair and plain question severally to three or four Mussulman physicians: "What is the Indian name of the plant which the Arabs call *Sumbulu'l Hind*?" They all answered, but some with more readiness than others, *Jatamansi*. After a pretty long interval, I shewed them the spikes (as they are called) of *Jatamansi*, and asked, what was the Arabic name of that Indian drug? They all answered readily, *Sumbulu'l Hind*. The same evidence may be obtained in this country by any other European who seeks it; and if among twelve native physicians, versed in Arabian and Indian philology, a single man should, after due consideration, give different answers, I will cheerfully submit to the Roman judgment of *non liquet*. But the *Jatamansi** evidently belongs to the natural order which Linnæus calls with the following *characters*: Plate CXX.

Calyx, scarce any; *margin*, hardly discernible. *Corolla*, one petal; *tube* somewhat gibbous; *border* five cleft. *Stamina*, three *Anthers*. *Pistula*, *Germ* beneath; one *Style* erect. *Seed*, solitary, crowned with a pappus. *Root*, fibrous. *Leaves*, hearted, fourfold; *radical* leaves petioled.

It appears therefore (continues the learned author) to be the Protean plant Valerian, a sister of the Mountain and Celtick Nard, and of a species which I should describe in the Linnean style, *Valeriana Jatamansi floribus triandris, foliis cordatis quaternis, radicalibus petiolatis*. The radical leaves, rising from the ground, and enfolding the young stem, are plucked up with a part of the root, and being dried in the sun or by artificial heat, are sold as a drug, which, from its appearance, has been called spikenard. The Jatamansi is a native of the most remote and hilly parts of India, such as NEPA'L, Marang Butan, near which Ptolemy fixes the native soil of the *Nardus Indica*. It grows erect above the surface of the ground, resembling an ear of green wheat; and when recent, it has a faint odour, which is greatly increased by the simple process of drying it.

NARES (JAMES), doctor of music, an eminent composer and teacher in that science, under whom some of the first musicians of the present day received the whole or part of their education, was the son of Mr Nares, who was, for many years, steward to Montague and Biog. Dict. new edit.

(A) In the Memoirs of the Academy of Sciences for 1767, Fougeroux has proved that the giallolino prepared by him produced on porcelain a much more beautiful colour than the Naples yellow sold in the shops.

Nares.

and Willoughby, earls of Abingdon. He was born, as well as his brother, the late Mr Juftice Nares, at Stanwell in Middlefex; the former in 1715, the latter in 1716. His mufical education he commenced under Mr Gates, then mafter of the royal chorifters; and completed it under the celebrated Dr Pepufch. Thus prepared, he officiated, for fome time, as deputy to Mr Pigott, organift of Windfor; but on the refignation of Mr Salifbury, organift of York, in 1734, was chofen to fucceed him, being then only nineteen. It is related, on undoubted authority, that, when the old mufician firft faw his intended fucceffor, he faid, rather angrily, "What! is that child to fucceed me?" which being mentioned to the organift elect, he took an early opportunity, on a difficult fervice being appointed, to play it throughout half a note below the pitch, which brought it into a key with feven fharps; and went through it without the flighteft error. Being afked why he did fo? he faid, that "he only wifhed to fhew Mr Salifbury what a child could do." His knowledge in all branches of his profeffion was equal to his practical fkill in this inftance; and, during his refidence at York, where he was abundantly employed as a teacher, and where he married, Mr Nares, by his good conduct, as well as profeffional merit, obtained many powerful friends. Among the foremoft of thefe was Dr Fontayne, the refpectable and venerable dean of York; who, when Dr Green died, towards the latter end of 1755, exerted his intereft fo fuccefsfully, that he obtained for him the united places of organift and compofer to his majefty. He removed therefore to London the beginning of 1756; and, about the fame time, was created doctor in mufic at Cambridge.

On the refignation of Mr Gates, in 1757, Dr Nares obtained alfo the place of mafter of the chorifters; which having been, for a long time, without increafe, notwithftanding the increafe of expences attending it, was, by royal favour, augmented about 1775, firft with the falary of the violift; and, on the revival of that place for Mr Crofdill, in 1777, with that of lutanift, which was annexed to it for ever. It was in this fituation that Dr Nares fuperintended the education of many pupils, who have fince become famous; particularly Dr Arnold, who, though with him only for a fhort time, was highly diftinguifhed by him for talents and application. The anthems and fervices which Dr Nares produced, as compofer to the royal chapel, were very numerous; many of them have fince been printed, and many which exift only in manufcript ftill continue to be performed in the choirs with much effect. Having been originally a mufician rather by accident than choice, with very ftrong talents and propenfities alfo for literature, Dr Nares was particularly attentive to exprefs the fenfe of the words he undertook to fet; and was the firft who attempted to compofe the Te Deum for the choir-fervice, in fuch a manner as to fet off the fentiments it contains to advantage. Before his time, it had been fet rather a regular ftrain of chaunt than to any expreffive melodies. The merits of Dr Nares were not overlooked by his royal patrons, whom he had occafionally the honour to attend in private, though not a part of his regular duty. To manifeft his refpect and gratitude for them, he compofed his dramatic ode, entitled The Royal Paftoral, the words of which were written by Mr Bellamy, author of a book, entitled Ethic Amufements.

In July 1780, Dr Nares was obliged, by declining health, to refign the care of the chorifters, in which place he was fucceeded by Dr Ayrton, his pupil and valued friend. In his fixty-eighth year, a conftitution, never robuft, gave way, and he died on February 10. 1783. Teftimony has been borne to the merits of Dr Nares by feveral writers, but more particularly by Mr Mafon, in his preface to a book of anthems, printed for the ufe of York Cathedral; and in his late Effays on Church Mufic, page 138. The late Lord Mornington, fo well known for mufical talents, frequently confulted him; and Sir John Hawkins derived advantage from his acquaintance, in the progrefs of his Hiftory of Mufic. Throughout life, he was not lefs refpected as a man than admired as a mufician; he had a vivacity that rendered his fociety always pleafing; and a generous contempt for every thing bafe, that manifefted itfelf on all proper occafions, and very juftly commanded efteem.

His printed works are thefe: 1. Eight Sets of Leffons for the Harpfichord; dedicated to the Right Hon. Willoughby Earl of Abingdon. Printed in 1748; reprinted in 1757. 2. Five Leffons for the Harpfichord, with a Sonata in fcore for the Harpfichord or Organ; dedicated to the Right Honourable the Countefs of Carlifle; publifhed in 1758 or 1759. 3. A Set of Eafy Leffons for the Harpfichord, three in number; with a dedication to the public, figned J. N. 4. A Treatife on Singing, fmall fize. 5. Il Principio; or A regular Introduction to playing on the Harpfichord or Organ. This was the firft fet of progreffive leffons publifhed on a regular plan. 6. The Royal Paftoral, a Dramatic Ode; dedicated to his Royal Highnefs the Prince of Wales; printed in fcore, with an overture and chorufes. 7. Catches, Canons, and Glees; dedicated to the late Lord Mornington. 8. Six Fugues, with Introductory Voluntaries for the Organ or Harpfichord. 9. A Concife and Eafy Treatife on Singing, with a Set of Englifh Duets for Beginners. A different work from the former fmall treatife. 10. Twenty Anthems, in fcore, for one, two, three, four, and five Voices. Compofed for the Ufe of his Majefty's Chapels Royal, 1778. 11. Six Eafy Anthems, with a favourite Morning and Evening Service, left for publication at his death, and publifhed in 1788, with a portrait and a concife account of the author. Of thefe compofitions the following fhort character is given by an eminent mufician, to whom they are all well known: "The leffons are compofed in a mafterly and pleafing ftyle; free from thofe tricks and unmeaning fucceffions of femitones, to which a good ear and found judgment never can be reconciled. The treatifes on finging contain duets compofed for the ufe of the children of the royal chapels, fuperior to any thing yet publifhed; and fuch as every teacher ought to perufe. His catches, canons, and glees, are natural and pleafing; efpecially the glee to all Lovers of Harmony, which gained the prize-medal at the catch-club in 1770. The Royal Paftoral is compofed throughout in a very mafterly manner; particularly the chorufes, with which each part concludes. This ode, containing 108 pages, was written, and all the vocal and inftrumental parts tranfcribed for performing, within twelve days. The

fix

six fugues, with introductory voluntaries for the organ, contain the strongest proofs of ingenuity and judgement; few, if any, have ever been written that can be preferred to them. In both sets of the anthems, the same characteristics appear; and the service of the latter very justly acquired the title of *favourite*; nor can there be any doubt that the works of this author will be admired as long as a taste for music shall subsist."

NAVIGATORS ISLANDS, an archipelago in the South Sea, discovered by Bougainville, who gave to them that name, because the natives do not pass between the different villages, which are all built in creeks and bays, but in their canoes. The Navigators Islands are ten in number; namely, *Opoun*, *Leoné*, *Fanfoue*, MAOUANA, *Oyolava*, *Calinasse*, *Pola*, *Shika*, *Ossamo*, and *Ouera*.

We have already given an account of the soil and productions of MAOUANA; and as the other islands of this cluster are equally fertile, we need not go over the same ground again. It may be proper, however, to observe, that in some of them the sugar-cane was found growing spontaneously, though its juice contained less of the saccharine substance than the sugar-cane of the West Indies, which our voyagers attributed to its growing in a richer soil and in the shade. According to Perouse, the Navigators Islands are situated about the 14th degree of south latitude, and between the 171st and 175th degrees of longitude west from Paris. In Oyolava the smoke was seen hovering over a village as over a large European town; and the number of canoes which from that island surrounded the frigates was immense. These are very ticklish vessels, and would be absolutely useless to any body but such excellent swimmers as the islanders, who are no more surprised or uneasy at their oversetting than we are at the fall of a hat. Taking up the canoe on their shoulders, they empty it of water, and then get in again, with the certainty of having the same operation to perform a second time in half an hour. Sometimes they join two canoes together by means of a cross piece of wood, in which they make a step to receive the mast; and in this way they are less liable to be overset, sometimes performing a long voyage without any such accident. It is needless to add, that these canoes are very small, generally containing only five or six persons, though some few of them may contain as many as fourteen.

The natives of the Navigators Islands are tall and well made. Their usual height is five feet nine, ten, and eleven inches; but their stature is less astonishing than the colossal proportions of the different parts of their bodies. "Our curiosity (says Perouse), which often led us to measure them, gave them an opportunity of making frequent comparisons of their bodily strength with ours. These comparisons were not to our advantage; and we perhaps owe our misfortunes (see MAOUANA in this *Suppl.*) to the idea of individual superiority resulting from repeated trials. Their countenances often appeared to express a sentiment of disdain, which I hoped to destroy, by ordering our arms to be used in their presence: but my end could only have been gained by directing them against human victims; for otherwise they took the noise for sport, and the trial for a diversion.

"Among these Indians a very small number is below the height indicated above. I have, however, measured several who were only five feet four inches, but these are the dwarfs of the country; and although their stature resembles ours, their strong and nervous arms, their broad chests, and their legs and thighs, are of a very different proportion.

"The men have the body painted or tatowed, so that any one would suppose them clad, although they go almost naked. They have only a girdle of sea-weeds encircling their loins, which comes down to their knees, and gives them the appearance of the river gods of fabulous history, whom it is customary to depict with rushes round their waist. Their hair is very long. They often twist it round their heads, and thus add to their native ferocity of countenance, which always expresses either surprise or anger. The least dispute between them is followed by blows of sticks, clubs, or paddles; and often, without doubt, costs the combatants their lives. They are almost all covered with scars, which can only be the consequence of their individual quarrels. The stature of the women is proportioned to that of the men. They are tall, slender, and not without grace; but they lose, while yet in their prime, those elegant forms, of which nature has not broken the mould among this barbarous race, but of which she appears to leave them in possession only for a moment, and with reluctance. Among a great number of women that I had an opportunity of seeing, I only observed three really pretty. The gross effrontery of the rest, the indecency of their motions, and the disgusting offers which they made of their favours, rendered them fit mothers and wives for the ferocious beings that surrounded us." Our author gives the following instance of indecent manners, which is, perhaps, without a parallel.

The young and prettiest females soon attracted the in spite of the Commodore's prohibition, endeavoured to form a connection with them, and were successful. The looks of the Europeans expressing desires which were soon divined, some old women undertook the negociation. The altar was prepared in the handsomest hut in the village, all the blinds were let down, and the inquisitive were excluded. The victim was then laid in the arms of an old man, who exhorted her, during the ceremony, to moderate the expression of her pain; while the matrons sang and howled: the ceremony being performed in their presence, and under the auspices of the old man, who served at once as priest and altar. All the women and children in the village were round the house, gently lifting up the blinds, and seeking to enjoy the sight through the smallest crevices in the mats. Whatever former navigators may have said, Perouse was convinced that, in the Navigators Islands at least, the young girls, before they are married, are mistresses of their persons, and that they are not dishonoured by their complaisance. It is even more than probable, that in marrying they are called to no account concerning their past conduct; but he had no doubt that they are obliged to be more reserved when provided with a husband.

These people cultivate certain arts with success. Under the article MAOUANA mention has been made of the elegant form which they give to their huts. It is not with such folly as is commonly supposed that they disdain our instruments of iron; for they finish their work

very

Navigators. very neatly with tools made of a very fine and compact species of basaltes in the form of an adze. For a few glass beads they sold to Perouse large three legged dishes of a single piece of wood, and so well polished that they seemed to have been laid over with a coat of the finest varnish. It would take an European workman several days to produce one of these dishes, which, for want of proper instruments, must cost an Indian several months labour. They set, however, scarcely any value upon them, because they set little upon the time they employ. The fruit trees and nutritious roots that grow spontaneously around them, insure to them their subsistence, as well as that of their hogs, dogs, and fowls; and if they sometimes stoop to work, it is to procure enjoyments rather agreeable than useful. They manufacture very fine mats, and some paper stuffs. Our author remarked two or three of them, whom he took for chiefs, with a piece of cloth tied round their waist like a petticoat, instead of a girdle of weeds. It is composed of real thread, prepared no doubt from some filamentous plant like the nettle or flax; and is manufactured without a shuttle, the threads being absolutely laid over one another like those of their mats. This cloth, which has all the suppleness and solidity of ours, is very fit for the sails of their canoes; and appeared far superior to the paper stuff of the Society and Friendly Islands, which they manufacture also. Their canoes are well constructed, and furnish a good proof of the skill with which they work in wood. For a few glass beads they gave to the Frenchmen, among other things, a wooden vessel filled with cocoa nut oil, exactly of the shape of our earthen pots, and such as no European would undertake to fashion by any other means than a turning lathe. Their ropes are round, and twisted like watch chains of ribbon: their mats are very fine; but their stuffs are inferior to those of the Easter and Sandwich Islands.

Perouse derives the natives of those islands, whose colour, he says, nearly resembles that of the Algerines and other nations on the coast of Barbary, from the Malays; and as we do not vouch for the truth of his theory, though we admit it to be ingenious, we shall give the reasoning by which he supports it in his own words.

"We did not at first discover (says he) any identity between their language and that of the natives of the Society and Friendly Islands, of which we had vocabularies; but a more mature examination convinced us, that they speak a dialect of the same language. A fact which tends to prove it, and which confirms the opinion of the English concerning the origin of these people, is, that a young domestic, a native of the province of Tagayan in the north of Manilla, understood and explained to us the greater part of their words. It is well known that the Tagayan, the Talgal, and the generality of languages spoken in the Philippines, are derived from the Malay: a language more diffused than were those of the Greeks and Romans, and common to the numerous tribes that inhabit the islands of the great Pacific Ocean. It appears to me evident, that all these different nations are the progeny of Malay colonies, which, in some age extremely remote, conquered the islands they inhabit. I should not even wonder, if the Chinese and Egyptians, whose antiquity is so much vaunted, were mere moderns in comparison of the Malays. But however this may be, I am satisfied that the aborigines of the Philippine Islands, Formosa, New Guinea, New Britain, the New Hebrides, the Friendly Islands, &c. in the southern hemisphere, and those of the Marianna and Sandwich islands in the northern, were that race of woolly headed men still found in the interior of the islands of Luconia and Formosa. They were not to be subjugated in New Guinea, New Britain, and the New Hebrides; but being overcome in the more eastern islands, which were too small to afford them a retreat in the centre, they mixed with the conquering nation. Thence has resulted a race of very black men, whose colour is still several shades deeper than that of certain families of the country, probably because the latter have made it a point of honour to keep their blood unmixed. I was struck with these two very distinct races in the Islands of Navigators, and cannot attribute to them any other origin.

"The descendants of the Malays have acquired in those islands a degree of vigour and strength, a lofty stature, and a Herculean form, which they do not inherit from their forefathers, but which they owe, without doubt, to an abundance of food, to a mild climate, and to the influence of different physical causes which have been constantly acting during a long series of generations. The arts which they perhaps brought with them may have been lost for want of materials and instruments to practise them; but the identity of language, like Ariadne's clue, enables the observer to follow all the windings of this new labyrinth. The feudal government is also preserved here: that government which little tyrants may regret; which was the disgrace of Europe for several centuries; and of which the Gothic remains are still to be found in our laws, and are the medals that attest our ancient barbarism: that government, which is the most proper to keep up a ferocity of manners, because the smallest disputes occasion wars of village against village, and because wars of this nature are conducted without magnanimity, and without courage. Surprises and treachery are employed by turns; and in these unfortunate countries, instead of generous warriors, nothing is to be found but base assassins (A). The Malays are still the most perfidious nation

(A) This was written under the old government of France by a man who, like other declaimers in the cause of liberty, forgot the excellencies, and insisted only on the defects of the feudal institutions. Had Perouse, however, returned to Europe, and witnessed the *philosophic* government of his country, he would have perceived, that *liberty* and *equality*, and *the rights of man*, are as well calculated to generate base assassins, as the Gothic remains of that government by which he supposed Europe to have been so long disgraced. He might even have lived to regret, that his lot was not cast among the bold and ferocious inhabitants of Maouana; for the treachery and cruelty of these people bears no proportion, even in his affecting narrative, to the systematic cruelty of those who decreed, that the end sanctifies the means, and that nothing, however atrocious in the estimation of antiquated moralists, is to be omitted, which contributes to elevate the mean above the noble.

tion of Asia and their children have not degenerated, because the same causes have led to and produced the same effects. It may be objected, perhaps, that it must have been very difficult for the Malays to make their way from west to east, to arrive at these different islands; but the westerly winds blow as frequently as the easterly in the vicinity of the equator, along a zone of seven or eight degrees from north to south, where the wind is so variable, that it is hardly more difficult to navigate east than west. Besides, these different conquests may not have been effected at the same time: the people in question may, on the contrary, have spread themselves by little and little, and gradually have introduced that form of government which still exists in the peninsula of Malacca, at Java, Sumatra, and at Borneo, as well as in all the other countries subject to that barbarous nation."

NAZER, Nazr, Nezer, Nuzzer, Nuzzerana; a present from an inferior; fees of office.

NEBULOUS, or Cloudy, a term applied to certain fixed stars which shew a dim hazy light; being less than those of the sixth magnitude, and therefore scarcely visible to the naked eye, to which at best they only appear like little dusky specks or clouds. Through a moderate telescope, these nebulous stars plainly appear to be congeries or clusters of several little stars.

NECKAR isle, a small barren island, or rather rock, discovered by Perouse in the Pacific Ocean. Though its sterility renders it of no importance in itself, its exact situation must be interesting to navigators, who are therefore obliged to the French Commodore for having ascertained its latitude to be 23° 34′ north, and its longitude to be 166° 52′ west from Paris. From the soundings the *Neckar* seemed to be only the top or nucleus of a much more considerable island, which, probably from being composed of a soft and dissoluble substance, the sea had gradually washed away. In proportion as the frigates left the shore, the depth, which at the distance of a mile was very little, gradually increased, till, at the distance of about ten miles, no bottom was found with a line of 150 fathoms; and over the whole of that shore the bottom consisted of coral and broken shells.

NEPAL, a kingdom of India, situated to the north-east of the city of Patna, at the distance of ten or twelve days journey. Within the distance of four days journey from Nepal the road is good in the plains of Hindostan, but in the mountains it is bad, narrow, and dangerous. At the foot of the hills the country is called *Teriani*; and there the air is very unwholesome from the middle of March to the middle of November; and people in their passage catch a disorder called in the language of that country *aul;* which is a putrid fever, and of which the generality of people, who are attacked with it, die in a few days; but on the plains there is no apprehension of it. Although the road be very narrow and inconvenient for three or four days at the passes of the hills, where it is necessary to cross and recross the river more than fifty times, yet, on reaching the interior mountain before you descend, you have an agreeable prospect of the extensive plain of Nepal, resembling an amphitheatre covered with populous towns and villages: the circumference of the plain is about 200 miles, a little irregular, and surrounded by hills on all sides, so that no person can enter or come out of it without passing the mountains. Nepal.

There are three principal cities in the plain, each of which was the capital of an independent kingdom; the principal city of the three is situated to the northward of the plain, and is called *Cat'hmandu:* it contains about 18,000 houses; and this kingdom, from south to north, extends to the distance of twelve or thirteen days journey as far as the borders of Tibet, and is almost as extensive from east to west. The king of Cat'hmandu has always about 50,000 soldiers in his service. The second city to the south-west of Cat'hmandu is called *Lelit Pattan*; it contains near 24,000 houses. The third principal city to the east of Lelit Pattan is called *B'hatgan:* it contains about 12,000 families, and is the metropolis of a district which extends toward the east to the distance of five or six days journey; and borders upon another nation, also independent, called *Ciratas*, who profess no religion. Besides these three principal cities, there are many other large and less considerable towns or fortresses; one of which is *Timi*, and another *Cipoli*, each of which contains about 8000 houses, and is very populous. All those towns, both great and small, are well built; the houses are constructed of brick, and are three or four stories high; their apartments are not lofty; they have doors and windows of wood well worked and arranged with great regularity. The streets of all their towns are paved with brick or stone, with a regular declivity to carry off the water. In almost every street of the capital towns there are also good wells made of stone, from which the water passes through several stone canals for the public benefit. In every town there are large square varandas well built, for the accommodation of travellers and the public: these varandas are called *Pali;* and there are also many of them, as well as wells, in different parts of the country for public use. There are also, on the outside of the great towns, small square reservoirs of water, faced with brick, with a good road to walk upon, and a large flight of steps for the convenience of those who choose to bathe.

The religion of Nepal is of two kinds: the more ancient is professed by many people who call themselves *Baryesu;* they pluck out all the hair from their heads; their dress is of coarse red woollen cloth, and they wear a cap of the same: they are considered as people of the religious order, and their religion prohibits them from marrying, as it is with the Lamas of Tibet, from which country their religion was originally brought; but in Nepal they do not observe this rule, except at their discretion. They have large monasteries, in which every one has a separate apartment or place of abode. They observe also particular festivals, the principal of which is called *Yatra* in their language, and continues a month or longer according to the pleasure of the king. The ceremony consists in drawing an idol, which at Lelit Pattan is called *Baghero*, in a large and richly ornamented car, covered with gilt copper: round about the idol stand the king and the principal Baryesus; and in this manner the vehicle is almost every day drawn thro' some one of the streets of the city by the inhabitants, who run about beating and playing upon every kind of instrument their country affords, which make an inconceivable noise.

The

The other religion, the more common of the two, is that of the Brahmens, and is the ſame as is followed in Hindoſtan, with the difference that, in the latter country the Hindus being mixed with the Mahommedans, their religion alſo abounds with many prejudices, and is not ſtrictly obſerved; whereas in Nepal, where there are no Muſſelmans (except one Caſhmirian merchant), the Hindu religion is practiſed in its greateſt purity: every day of the month they claſs under its proper name, when certain ſacrifices are to be performed and certain prayers offered up in their temples: the places of worſhip are more in number in their towns than are to be found in the moſt populous and moſt flouriſhing cities of Chriſtendom; many of them are magnificent according to their ideas of architecture, and conſtructed at a very conſiderable expence; ſome of them have four or five ſquare cupolas, and in ſome of the temples two or three of the extreme cupolas, as well as the doors and windows of them, are decorated with gilt copper.

In the city of Lelit Pattan the temple of Baghero is more valuable, on account of the gold, ſilver, and jewels it contains, than even the houſe of the king. Beſides the large temples, there are alſo many ſmall ones, which have ſtairs, by which a ſingle perſon may aſcend, on the outſide all around them; and ſome of thoſe ſmall temples have four ſides, others ſix, with ſmall ſtone or marble pillars poliſhed very ſmooth, with two or three pyramidal ſtories, and all their ornaments well gilt, and neatly worked according to their ideas of taſte. On the outſide of ſome of their temples there are great ſquare pillars of ſingle ſtones from twenty to thirty feet high, upon which they place their idols ſuperbly gilt. The greateſt number of their temples have a good ſtone ſtaircaſe in the middle of the four ſquares, and at the end of each flight of ſtairs there are lines cut out of ſtone on both ſides: around about their temples there are alſo bells, which the people ring on particular occaſions; and when they are at prayers, many cupolas are alſo quite filled with little bells hanging by cords in the inſide about the diſtance of a foot from each other, which make a great noiſe on that quarter where the wind conveys the ſound. There are not only ſuperb temples in their great cities, but alſo within their caſtles.

To the eaſtward of Cat'hmandu, at the diſtance of about two or three miles, there is a place called *Tolu*, by which there flows a ſmall river, the water of which is eſteemed holy, according to their ſuperſtitious ideas, and thither they carry people of high rank, when they are thought to be at the point of death: at this place there is a temple, which is not inferior to the beſt and richeſt in any of the capital cities. They alſo have it on tradition, that at two or three places in Nepal valuable treaſures are concealed under ground: one of thoſe places they believe is Tolu; but no one is permitted to make uſe of them except the king, and that only in caſes of neceſſity. Theſe treaſures, they ſay, have been accumulated in this manner: When any temple had become very rich from the offerings of the people, it was deſtroyed, and deep vaults dug under ground one above another, in which the gold, ſilver, gilt copper, jewels, and every thing of value, were depoſited. This was found to be actually the caſe when the miſſionary, from whoſe memoir this account of Nepal is taken, was at Cat'hmandu. One of the kings, or pretenders to the crown, who were then at war with each other, being in the utmoſt diſtreſs for want of money to pay his troops, ordered the vaults at Tolu to be opened; and found in the firſt vault more money, beſides ſilver and gold too! than [illegible]diate occaſion for.

To the weſtward alſo of the great city [illegible] Lelit Pattan, at the diſtance of only three miles, is a caſtle called *Banga*, in which there is a magnificent temple. No one of the miſſionaries ever entered into this caſtle; becauſe the people who have the care of it, have ſuch a ſcrupulous veneration for the temple, that no perſon is permitted to enter it with his ſhoes on; and the miſſionaries, unwilling to ſhew ſuch reſpect to their falſe deities, never entered it. The author of this memoir, however, who acted as phyſician to the commandant, was of courſe admitted within the caſtle, and got a ſight of the celebrated temple, which he declares, that for magnificence he believes ſuperior to every thing in Europe.

Beſides the magnificence of the temples, which their cities and towns contain, there are many other rarities. At Cat'hmandu, on one ſide of the royal garden, there is a large fountain, in which is one of their idols called *Narayan*. This idol is of blue ſtone, crowned and ſleeping on a mattraſs alſo of the ſame kind of ſtone, and the idol and the mattraſs appear as floating upon the water. This ſtone machine is very large, being about 18 or 20 feet long, and broad in proportion, but well worked, and in good repair.

In a wall of the royal palace of Cat'hmandu, which is built upon the court before the palace, there is a great ſtone of a ſingle piece, which is about fifteen feet long, and four or five feet thick; on the top of this great ſtone there are four ſquare holes at equal diſtances from each other; in the inſide of the wall they pour water into the holes; and in the court ſide, each hole having a cloſed canal, every perſon may draw water to drink. At the foot of the ſtone is a large ladder, by which people aſcend to drink; but the curioſity of the ſtone conſiſts in its being quite covered with characters of different languages cut upon it. Some lines contain the characters of the language of the country, others the characters of Tibet, others Perſian, others Greek, beſides ſeveral others of different nations; and in the middle there is a line of Roman characters, which appears in this form, AVTOMNEW INTER LHIVERT; but none of the inhabitants have any knowledge how they came there, nor do they know whether or not any European had ever been in Nepal before the miſſionaries, who arrived there only the beginning of the preſent century. They are manifeſtly two French names of ſeaſons, with an Engliſh word between them.

There is alſo to the northward of the city of Cat'hmandu a hill called *Simbi*, upon which are ſome tombs of the Lamas of Tibet, and other people of high rank of the ſame nation. The monuments are conſtructed after various forms: two or three of them are pyramidal, very high, and well ornamented; ſo that they have a very good appearance, and may be ſeen at a conſiderable diſtance. Round theſe monuments are remarkable ſtones covered with characters, which probably are the inſcriptions of ſome of the inhabitants of Tibet whoſe bones were interred there. The natives of Nepal not only look upon the hill as ſacred, but imagine it is protected by their idols; and from this erroneous ſuppoſition never think of ſtationing troops there for the defence

defence of it, although it be a post of great importance, and only at a short mile's distance from the city. During the hostilities, however, which prevailed when our author was in the country, this sacred hill was fortified by one of the armies, who, in digging their ditches among the tombs, found considerable pieces of gold, with a quantity of which metal the corpses of the grandees of Tibet are always interred.

The kingdom of Nepal our author believes to be very ancient, because it has always preserved its peculiar language and independence. It was completely ruined, however, about thirty or forty years ago by the dissensions of its nobles, who, on the death of their sovereign, and, as it would seem, the extinction of the royal line, could not agree in their choice of a proper successor. The consequence was, that different sovereigns were set up by the nobles of different districts; and these waged war with each other, with a degree of treachery and savage atrocity that has hardly a parallel in the annals of the world Even the Brahmens, whom we are accustomed to consider as a mild and innocent people, were, in the civil wars of Nepal, guilty of the meanest and basest villanies: they brought about treaties between the rival sovereigns, and then encouraged him whom they favoured, to massacre the adherents of the other in cold blood.

NEWTON (John), an eminent English mathematician, was born at Oundle in Northamptonshire, 1622. After a proper foundation at school, he was sent to Oxford, where he was entered a commoner of St Edmund's Hall in 1637. He took the degree of bachelor of arts in 1641; and the year following was created master, among several gentlemen that belonged to the king and court, then residing in the university. At which time, his genius being inclined to astronomy and the mathematics, he applied himself diligently to those sciences, and made a great proficiency in them, which he found of service during the times of the usurpation. After the restoration of Charles II. he reaped the fruits of his loyalty; being created doctor of divinity at Oxford Sept. 1661, he was made one of the king's chaplains, and rector of Ross in Herefordshire, in the place of Mr John Toombes, ejected for nonconformity. He held this living till his death, which happened at Ross on Christmas-day 1678. Mr Wood gives him the character of a capricious and humoursome person: however that may be, his writings are sufficient monuments of his genius and skill in the mathematics. These are, 1. *Astronomia Britannica*, &c. in three parts, 1656, in 4to. 2. Help to Calculation; with Tables of Declination, Ascension, &c. 1657, 4to. 3. *Trigonometria Britannica*, in two books, 1658, *folio*; one composed by our author, and the other translated from the Latin of Henry Gellibrand. 4. *Chiliades centum Logarithmorum*, printed with, 5. Geometrical Trigonometry, 1659. 6. Mathematical Elements, three parts, 1660, 4to. 7. A perpetual Diary or Almanac, 1662. 8. Description of the Use of the Carpenter's Rule, 1667. 9. Ephemerides, shewing the Interest and rate of Money at 6 *per cent.* &c. 1667. 10 *Chiliades centum Logarithmorum, et Tabula Partium proportionalium*, 1667. 11. The Rule of Interest, or the Case of Decimal Fractions, &c. Part II 1668, 8vo. 12. School-Pastime for young Children, &c. 1669, 8vo 13. Art of practical Gauging, &c. 1669. 14. Introduction to the Art of Rhetoric, 1671. 15. The Art of Natural Arithmetic, in whole Numbers, and Fractions Vulgar and Decimal, 1671, 8vo. 16. The English Academy, 1677, 8vo. 17. Cosmography. 18. Introduction to Astronomy. 19. Introduction to Geography, 1678, 8vo *

NICOLE (Francis), a very celebrated French mathematician, was born at Paris December 23. 1683 His early attachment to the mathematics induced M. Montmort to take the charge of his education; and he opened out to him the way to the higher geometry. He first became publicly remarkable by detecting the fallacy of a pretended quadrature of the circle. This quadrature a M Mathulon so assuredly thought he had discovered, that he deposited, in the hands of a public notary at Lyons, the sum of 3000 livres, to be paid to any person who, in the judgment of the Academy of Sciences, should demonstrate the falsity of his solution. M. Nicole, piqued at this challenge, undertook the task, and exposing the paralogism, the Academy's judgment was, that Nicole had plainly proved that the rectilineal figure which Mathulon had given as equal to the circle, was not only unequal to it, but that it was even greater than the polygon of 32 sides circumscribed about the circle. The prize of 3000 livres Nicole presented to the public hospital of Lyons.

Nicole.

* Eng. Dict New ed.

The Academy named Nicole, Eleve-Mechanician, March 12. 1707; Adjunct in 1716, Associate in 1718, and Pensioner in 1724; which he continued till his death, which happened the 18th of January 1758, at 75 years of age.

His works were all inserted in the different volumes of the Memoirs of the Academy of Sciences; and are as follow: 1. A General Method for determining the Nature of Curves formed by the Rolling of other Curves upon any Given Curve; in the volume for the year 1707. 2. A General Method for Rectifying all Roulets upon Right and Circular Bases, 1708. 3. General Method of determining the Nature of those Curves which cut an Infinity of other Curves given in Position, cutting them always in a Constant Angle, 1715. 4. Solution of a Problem proposed by M. de Lagny, 1716. 5. Treatise of the Calculus of Finite Differences, 1717. 6. Second Part of the Calculus of Finite Differences, 1723. 7. Second Section of ditto, 1723. 8. Addition to the two foregoing papers, 1724. 9 New Proposition in Elementary Geometry, 1725. 10. New Solution of a Problem proposed to the English Mathematicians, by the late M. Leibnitz, 1725. 11. Method of Summing an Infinity of New Series, which are not summable by any other known method, 1727. 12. Treatise of the Lines of the Third Order, or the Curves of the Second Kind, 1729. 13. Examination and Resolution of some Questions relating to Play, 1730. 14. Method of determining the Chances at Play. 15 Observations upon the Conic Sections, 1731. 16. Manner of generating in a Solid Body all the Lines of the Third Order, 1731. 17. Manner of determining the Nature of Roulets formed upon the Convex surface of a Sphere; and of determining which are Geometric and which are Rectifiable, 1732. 18. Solution of a Problem in Geometry, 1732. 19. The Use of Series in resolving many Problems in the Inverse Method of Tangents, 1737. 20 Observations on the Irreducible Case in Cubic Equations, 1738. 21. Observations upon Cubic Equations, 1738. 22. On the Trisection of an

Nieuwland. on Angle, 1740. 23. On the Irreducible Case in Cubic Equations, 1741. 24. Addition to ditto, 1743. 25. His Last Paper upon the same, 1744. 26. Determination, by Incommensurables and Decimals, the Values of the Sides and Areas of the Series in a Double Progression of Regular Polygons, inscribed in and circumscribed about a Circle, 1747 *.

* Hutton's Dictionary.

NIEUWLAND (Peter), professor of mathematics and natural philosophy in the university of Leyden, was born at Diemermeer, a village near Amsterdam, on the 5th of November, 1764. His father, by trade a carpenter, having a great fondness for books, and being tolerably well versed in the mathematics, instructed his son himself till he attained to his eleventh year. Young Nieuwland appears to have displayed strong marks of genius at a very early period. When about the age of three, his mother put into his hand some prints, which had fifty verses at the bottom of them by way of explanation. These verses she read aloud, without any intention that her son should learn them; and she was much surprised some time after to hear him repeat the whole from memory, with the utmost correctness, on being only shewn the prints.

Before he was seven years of age he had read more than fifty different books, and in such a manner that he could frequently repeat passages from them both in prose and in verse. When about the age of eight, Mr Aeneæ at Amsterdam, one of the greatest calculators of the age, asked him if he could tell the solid contents of a wooden statue of Mercury which stood upon a piece of clock-work. "Yes (replied young Nieuwland), provided you give me a bit of the same wood of which the statue was made; for I will cut a cubic inch out of it, and then compare it with the statue." Poems which (says his eulogist) display the utmost liveliness of imagination, and which he composed in his tenth year, while walking or amusing himself near his father's house, were received with admiration, and inserted in different poetical collections.

Such an uncommon genius must soon burst through those obstacles which confine it. Bernardus and Jeronimo de Bosch, two of the first and wealthiest men at Amsterdam, became young Nieuwland's benefactors, and contributed very much to call forth his latent talents. He was taken into the house of the former in his eleventh year, and he received daily instruction from the latter for the space of four years. While in this situation he made considerable progress in the Latin and Greek languages, and he studied philosophy and the mathematics under Wyttenbach. In the year 1783 he translated the two dissertations of his celebrated instructors, Wyttenbach and de Bosch, on the opinions which the ancients entertained of the state of the soul after death, which had gained the prize of the Teylerian theological society.

From the month of September 1784 to 1785, Nieuwland resided at Leyden as a student in the university, and afterwards applied with great diligence, at Amsterdam, to natural philosophy and every branch of the mathematics, under the direction of Professor van Swinden. He had scarcely begun to turn his attention to chemistry, when he made himself master of the theory of the much-lamented Lavoisier, and could apply it to every phenomenon. He could read a work through with uncommon quickness, and yet retain in his mind the principal part of its contents. Nieuwland.

Nieuwland's attention was directed to three principal pursuits, which are seldom united; poetry, the pure mathematics, and natural philosophy. In the latter part of his life he added to these also astronomy. Among the poems which he published, his Orion alone has rendered his name immortal in Holland. Of the small essays which he published in his youth, the two following are particularly deserving of notice: 1. A Comparative View of the Value of the different Branches of Science; and, 2. The best Means to render general, not Learning, but Soundness of Judgment and Good Taste.

One of his great objects was to bring the pure mathematics nearer to perfection, to clear up and connect their different parts, and in particular to apply them to natural philosophy and astronomy. Cornelius Douwes discovered an easy method of determining the latitude of a place at sea, not by the meridian altitude of the sun, but by two observations made at any other period of the day. This method, however, being still imperfect, Nieuwland turned his thoughts towards the improvement of it, and in the beginning of the year 1789 wrote a paper on the subject, which he transmitted to M. de Lalande at Paris, from whom it met with great approbation. In the year 1792, when Nieuwland resided two months at Gotha with Major von Zach, these two learned men often conversed on this method of finding the latitude, and calculated the result of observations which they had made with a sextant and an artificial horizon. The above paper, enlarged by these observations, was inserted by Major von Zach with Nieuwland's name in the first Supplement to Bode's Astronomical Almanack, Berlin, 1793.

This, however, was not the only service which Nieuwland endeavoured to render to astronomy. It had been observed by Newton, Euler, De la Place, and others, that the axes of the planets do not stand perpendicular, but inclined, to the plane of their orbits; and Du Sejour, in his analytical treatise on the apparent motion of the heavenly bodies, considers it as highly probable that this phenomenon depends on some *physical* cause; which, however, he does not venture to assign. Nieuwland proceeded farther, and laid down principles, from which he drew this conclusion, that the above phenomenon is intimately connected with the whole system of attraction. On these principles he made calculations, the result of which was exactly equal to the angle of the inclination of the earth's axis to the plane of its orbit. Nieuwland communicated his discovery with much modesty to the celebrated Professor Damen at Leyden, who proposed some objections to it which discouraged Nieuwland, and induced him to revise his calculations with more accuracy. Major von Zach transmitted the paper which contained them to M. De la Place at Paris, and caused it to be printed also, for the opinion of the learned, in the Supplement to Professor Bode's Astronomical Almanack for the year 1793.

The writer of this article is not acquainted either with the principles which this young astronomer assumed, or with the calculations which he made from them; but if he holds gravitation to be essential to matter, and the inclination of the axes of the planets to be the necessary result of the law of gravitation, he is undoubtedly

Nieuwland. doubtedly in an error. The axes of the planets are not all equally inclined, nor does the inclination vary in exact proportion to the squares of the distances.

Nieuwland's talents and diligence soon recommended him to the notice of his country. In his twenty-second year, he was appointed a member of the commission chosen by the College of Admiralty at Amsterdam for determining the longitude and improving marine charts. On this labour he was employed eight years, and undertook also to prepare a nautical almanack, and to calculate the necessary tables. The mathematical part was in general entrusted to Nieuwland; but he assisted also his two colleagues van Swinden and van Keulen, in the departments assigned to them, with such assiduity, that most of the work published on the longitude, together with the three additional parts, were the fruits of his labour. In the second edition of the explanation of the nautical almanack, he had also the principal share; and he was the author, in particular, of the explanation of the equation of time, the method of determining the going of a time-piece, and of calculating the declination of the moon.

Soon after Nieuwland engaged in this employment, it appeared as if his destination was about to be changed. In the year 1787, he was chosen by the States of Utrecht to succeed Professor Hennert; but on account of certain circumstances this appointment did not take place. He was, however, invited to Amsterdam by the magistrates of that city, to give lectures on mathematics, astronomy, and navigation. While in this situation, he wrote his useful and excellent treatise on navigation, the first part of which was published at Amsterdam in 1793, by George Hulst van Keulen; and it is much to be wished that M. van Swinden would complete this work from the papers bequeathed to him by his deceased friend the author.

In astronomical pursuits, Nieuwland applied not only to the theoretical, but also to the practical part; and in this study he was encouraged and assisted by Major von Zach, with whom he resided some time in the course of the year 1792, and who instructed him in the proper use of the sextant. This affectionate friend published also all his observations and calculations in the before-mentioned Supplement to Bode's Astronomical Almanack.

In the year 1789, Nieuwland was chosen member of a learned society whose object was chemical experiments; and so apt was his genius for acquiring knowledge, that in a little time he made himself completely master of the theory of chemistry. A proof of this is the treatise which he read on the 24th of May 1791, in the society, distinguished by the motto of *Felix Meritis*, and which has been printed in the first part of the New General Magazine (*Niew Algemeen Magazyn*). At the same time he was able to examine the important discoveries made by the society, to assist in preparing an account of them for the press, and to publish them with sufficient accuracy in the French language. Three parts of this work appeared under the title of *Recherches Physico-chymiques*. The first part appeared in 1792, and was afterwards reprinted in the *Journal de Physique*. The second was published in 1793, and the fourth in 1794. Some letters of his on chemistry may be found also in a periodical work called *The Messenger* (*Letterbode*).

This ingenious and diligent man was of great service Nieuwland. also in the philosophical department to the above society, *Felix Meritis*, of which he had been chosen a titular member on the 25th of January 1788, and an honorary member on the 15th of March 1791. The papers for which it was indebted to him are as follows:—1. On the Newest Discoveries in Astronomy, and the Progress lately made in that Science, 1788. This is an extract from a Latin oration which he intended to deliver at Utrecht when he expected to succeed Professor Hennert.—2. On the Figure of the Earth, 1789.—3. On the Course of Comets, and the Uncertainty of the Return of the Comet now Expected, 179..—4. On the Nature of the Mathematics. The principal object of this paper was to illustrate the idea, that the mathematics may be considered as a beautiful and perfect language.—5. On the Periodical Decrease or Increase in the Light of Certain Fixed Stars, and Particularly of the Star Algol, 1790.—6. On the Solution of Spherical Trigonometry by Means of a New Instrument Invented by Le Guin, 1791. M. le Guin having transmitted to the College of Admiralty at Amsterdam an instrument which might be used with great advantage in trigonometrical operations, and by which in calculating the longitude, one could deduce the real from the apparent distance, the admiralty charged Nieuwland to examine this instrument; and he found that it might be of excellent service for the above purpose.—7. On the Relative Value or Importance of the Sciences, 1791.—8. On the System of Lavoisier, 179..—9. On the Selenotopographia of Schröder, 1793.—10. On what is Commonly Called Cultivation, Instruction, or Enlightening, 1793.

Nieuwland had applied closely to the mathematics, astronomy, and navigation, for six years; during which time he made considerable improvements in nautical charts, and filled up his vacant hours with the study of philosophy and chemistry. In the month of July 1793 he was invited to the university of Leyden, to be professor of philosophy, astronomy, and the higher mathematics, in the room of the celebrated Damen; and the admiralty of Amsterdam requested him to continue his nautical researches, which he did with great assiduity till the period of his death. The only variation which he now made in his studies related to natural philosophy, for with the mathematics he was already sufficiently acquainted. He applied therefore to the experimental part, and spared no pains nor labour to become perfect in it; which would certainly have been the case, had he not been snatched from science and his friends at the early age of thirty. He died of an inflammation in his throat, accompanied with a fever, on the 13th of November 1794.

In his external appearance, Nieuwland was not what might be called handsome, nor had he ever been at pains to acquire that ease of deportment which distinguishes those who have frequented polite company. His behaviour and conversation were however agreeable, because he could discourse with facility on so many subjects, and never wished to appear but under his real character. On the first view one might have discerned that he was a man of great modesty and the strictest morality. His father was a Lutheran, and his mother a baptist; but he himself was a member of what is called the reformed church, *i. e.* a Calvinist, and always shewed

ed the utmost respect for the Supreme Being both by his words and his actions.

NIGER, a large river in Africa, of which many erroneous accounts have been published, and among them that which we have given in the *Encyclopædia Britannica*. By Herodotus, Pliny, Ptolemy, and other ancient authors, it is uniformly said to flow from *west* to *east*, dividing Africa as the Danube divides Europe; and from the report of the Africans, the first of these authors calls it a large river abounding with crocodiles. In the twelfth century, however, Edrisi describes the Niger, which he calls the Nile of the negroes, as running from *east* to *west*, and falling into the Atlantic Ocean, and his account was universally adopted by subsequent writers, till its falsehood was discovered by the African Association. From a number of concurring reports, Major Houghton was led to believe that the course of the Niger is from *west* to *east*, according to the most ancient account; and the truth of these reports has been established beyond all controversy by Mr Park, who saw the Niger himself, and actually accompanied it for many miles in its majestic course as laid down by Herodotus.

This river rises in or near the country of MANDING (which see in this *Supplement*), between the parallels of 10 and 11 degrees of north latitude, and between the 5th and 9th degree of west longitude, which comprehends a space the most elevated of all this portion of Africa. This is evident from the opposite courses of the three great rivers which rise in it. These are the Gambia, which runs to the west north-west; the Senegal, which runs to the north-west; and the Joliba (A), or Niger, running to the east-north-east. The head of the principal branch of the Senegal river is about 80 geographical miles to the west of that of the Niger; and the head of the Gambia is again about 100 miles west of the Senegal.

Mr Park traced the Niger to Silla, a considerable town about 420 miles from its source; and it was there larger than the Thames at Westminster. But 420 miles are but a very small part of the course of the Niger, which doubtless receives many tributary streams before it reach Kassina, 700 miles farther eastward, where there is every reason to believe that it was viewed by the ancient Romans. Our traveller collected at Silla what information he could from the Moorish and Negro traders concerning the further course of this majestic stream, as well as of the kingdoms through which it runs; and the following notices he believes to be authentic:

Two short days journey to the eastward of Silla, is the town of Jenne, which is situated on a small island in the river; and is said to contain a greater number of inhabitants than Sego itself, or any other town in Bambarra. (See SEGO, *Suppl.*) At the distance of two days more, the river spreads into a considerable lake, called *Dibbie* (or the dark lake); concerning the extent of which, all the information which our author could obtain was, that in crossing it, from west to east, the canoes lose sight of land one whole day. From this lake, the water issues in many different streams, which terminate in two large branches, one whereof flows towards the north-east, and the other to the east; but these branches join at Kabra, which is one day's journey to the southward of Tumbuctoo, and is the port or shipping-place of that city. The tract of land which the two streams encircle, is called Jinbala, and is inhabited by negroes; and the whole distance by land, from Jenne to Tumbuctoo, is twelve days journey.

From Kabra, at the distance of eleven days journey, down the stream, the river passes to the southward of Houssa, which is two days journey distant from the river. Of the further progress of this great river, and its final exit, all the natives with whom Mr Park conversed seemed to be entirely ignorant. Their commercial pursuits seldom induce them to travel further than the cities of Tumbuctoo and Houssa; and as the sole object of those journeys is the acquirement of wealth, they pay but little attention to the course of rivers, or the geography of countries. It is, however, highly probable that the Niger affords a safe and easy communication between very remote nations. All our author's informants agreed, that many of the negro merchants who arrive at Tumbuctoo and Houssa, from the eastward, speak a different language from that of Bambarra, or any other kingdom with which they are acquainted. But even these merchants, it would seem, are ignorant of the termination of the river; for such of them as can speak Arabic, describe the amazing length of its course in very general terms, saying only, that they believe *it runs to the world's end*.

Major Rennel, by comparing a great many accounts of the progress of this river beyond Houssa, with the idea which prevails in that city of its termination, has shewn it to be in a very high degree probable, that the waters of the Niger have no direct communication with the sea, but that they are spread out into a great lake in Wangara and Ghana, and evaporated by the heat of the sun. See WANGARA in this *Supplement*.

NILE, the name of a celebrated river, which, as it has been described in the *Encyclopædia*, should not have been introduced into this place, did we not think ourselves bound candidly to confess that, in our opinion, its sources, at least those sources which were the objects of ancient curiosity, have never yet been seen by any European. This seems to be proved, beyond the possibility of controversy, by Major Rennel in the Appendix to Mr Park's Travels, and by Mr Browne in his account of the *Bahr-el-abiad*, and *Dar-Fur* or *Soudan*. See SOUDAN in this *Supplement*.

Mr Bruce himself acknowledges that the Nile, which waters Egypt, is the confluence of two streams, and that the western stream, which he, with others, calls *Bahr-el-abiad*, or the *white river*, is the largest of the two. Were a man therefore to travel from Cairo up the banks of the Nile in quest of its source, he would, doubtless, when he should arrive at the division of the river into two channels, continue his journey up the greater of these; for what could induce him to turn aside with the less? Not the *name*; for neither the less nor the greater has by itself the name which, in Egypt, is given to both when united. The former, which undoubtedly has its source in Abyssinia, is there called the Abay or Abavi; and, in other countries through which

(A) This is the negro name of the river, and signifies the *great water*.

Nile, Nimiquas.

which it runs, the Bahr el Afrek; the latter is, from its source to its junction with the Abay, called the Bahr el abiad. Pliny believed that the Nile came from the west; and Ptolemy says expressly that its remote source is in the *mountains of the moon*. But this Nile must be the White River, which certainly rises to the westward of Abyssinia, and, according to Abulfeda, in the mountains of Komri or Kummeri; which, in Arabic, signifies *lunar*, being the adjective of Kummer, the moon.

In perfect conformity with this ancient account of the source of the Nile, Mr Ledyard was told at Cairo by certain persons from Dar Fur, that this celebrated river has its coy fountains in their country, at the distance of 55 days journey to the westward of Sennar, which brings them to the Komri mountains of Abulfeda, who, as well as Ptolemy and Edrisi, places the head of the Nile in a quarter far removed from Abyssinia. Ptolemy has indeed mentioned both branches; and while he describes the eastern in such a way as that it cannot be taken for any other than the Abyssinian branch, or the Nile of Bruce and the Portuguese Jesuits, speaks of a larger branch flowing from a more distant source, situated to the south-west. But this can be no other than Bruce's white river, the *Bahr el abiad* of Ledyard and Browne. It is true, there is an apparent difference in the account given by these two last mentioned travellers of the country in which the Bahr el-abiad rises; but it is a difference only apparent. Ledyard was told at Cairo that it rises in Dar-Fur; Mr Browne, who resided long in Dar Fur, was there told, that the sources of the river are near to a place called *Donga*, the residence of the chief or king of an idolatrous nation to the southward of Dar-Fur. It is to be observed, however, that the slave-merchants who trade between Donga and Cairo are always attached to the Soudan or Dar-Fur caravan; and that therefore the persons who told Ledyard that the Nile rises in their country were probably from Donga, though he took them for Furians from the name of their caravan. Mr Browne informs us, that the country about Donga is very mountainous, and that in the spot where the river rises there are said to be forty distinct hills, which are called *Kumri*. From them issues a great number of springs, that, uniting into one great channel, form the Bahr el abiad, which suffers the same periodical increase and diminution as the Nile in Egypt. The people of Donga are quite naked, black, and, as we have already observed, idolaters. Major Rennel places the mountains of the moon between 5° 40′ and 8° 10′ N. Lat. and between 24° 30′ and 30° 25′ E. Long. Their latitude and longitude, as laid down by Mr Browne, are somewhat, tho' very little, different; whilst Geesh, the source of Bruce's Nile, lies between the 10th and 11th degree of N. Lat. and in about the 37th degree of E. Long.

NIMIQUAS, a nation, or, more properly, two tribes in South Africa, called by Vaillant the *Less* and *Greater* Nimiquas.

The country of the Less Nimiquas extends in longitude from the mountains of Camis to the sea on the west, *i. e.* from 15° 25′ to 18° 25′ east from London, and in latitude from 28° 12′ to 29° 36′ south. From the information which our author could collect, he thinks that the number of inhabitants throughout the whole of this tract does not exceed 6000 souls. Even this number is annually diminished by the frequent attacks of Boshmen, and the aridity of the soil. Of the BOSHMEN we have already given such an account as can leave no doubt of the destructive nature of their incursions; and the soil must be arid indeed, if it be true, as Vaillant assures us, that in the country of the Less Nimiquas rain never falls except when it thunders, and that thunder is so rare as frequently not to be heard for the space of a whole year.

For this want of rain our author accounts in a satisfactory manner: "The country (he says) having neither forests nor lofty mountains to arrest the clouds, those which come from the north pass freely over it, and proceed on to Camis, where they burst and fall, either in rain in the valleys, or in snow on the summits of these mountains, which are the loftiest throughout the south of Africa." The country is of course not fruitful, and its sterility obliges the inhabitants frequently to change their residence, so that they are the most wandering of all the Hottentot tribes. In this barren region the Dutch colonists suppose that gold mines may be found; but our author discovered among the hordes no traces of this metal, though he found many indications of rich copper mines.

The Less Nimiquas, though of a tolerable stature, are not so tall as their neighbours to the eastward; and indeed Vaillant affirms, that the people to the east in the southern part of Africa are much superior to those of the west both in moral and physical qualities, while the animals are far inferior. The Less Nimiquas are great believers in witchcraft; and our author gives a ridiculous account of an interview that he had with an old witch named *Kakoes*, who had a complete ascendency, not only over the whole horde, but also over the savage Boshmen. These robbers, he says, never attempted to plunder the territory where she took up her residence; and she has been known, when their thefts came to her knowledge, to proceed alone, and unguarded, to their retreats in the midst of the woods, to threaten them with her vengeance, and thus compel them to a restitution of the stolen property. All her influence, however, over her own tribe, could procure for our author and his attendants only six sheep.

The women of the horde received his Hottentots with great kindness; and permitted them to discover very singular charms, of which it is needless here to insert a description. Among this people he saw abundance of bracelets, necklaces, and ear-rings of copper; and some of these ornaments were so well made and finely polished, that they must have been manufactured in Europe, and the fruits of an intercourse with the whites. But he saw several others, which, from their grotesque shape and rude workmanship, evidently shewed that they were fabricated by the savages themselves.

"These ornaments (says he) are worn by the Nimiquas in the same manner as by the other savages: yet I observed among them some whimsical peculiarities. I have seen persons with six ear-rings of the same shape in one ear, and none in the other: I have seen some with bracelets from the wrist to the elbow on one arm, while the other arm was bare: I have seen others with one side of the face painted in compartments of various colours, while on the other side both the colours and figures were different. In general, I observed a great propensity to ornaments among the Less Nimiquas,

Nimiquas. for their krosses and all their garments were plentifully covered with glass and copper beads, strung on threads, and fastened on every part of their dress. They even wore them in their hair, which was plastered with grease in the most disgusting manner. Many had their heads covered with a reddish incrustation, composed of grease and a powder resembling brick dust, with which their hair was so pasted together, that you would have sworn it to be a cap of red mortar. Those who had it in their power to display this luxury of dress, were as proud as are our *petits maitres*, when they can shake a head loaded with powder, perfume, and pomatum. The *nuyp kros*, or short apron, of the women, was adorned with rows of glass beads hanging down to their feet; in other respects they were dressed like the other Hottentots."

The country of the *Greater Nimiquas* is placed by the author in nearly the same longitude with that of the Less, and between 25° and 28° south latitude. It is barren like the other; but the people are much taller, being generally about five feet ten inches high. The men are dull and stupid, but the women are lively and extremely amorous; and both men and women are comparatively handsome and of a slender make. Extravagantly addicted to smoking tobacco, the young girls bartered their favours for a single pipe; and as Vaillant was chief of the caravan, a white, and possessor of tobacco of much better quality, many advances were made to him. "I have do doubt (says he) but I might have formed, for a few pipefuls only, an alliance with every family in the horde. I was even pressed so closely, as to be obliged to employ some resistance: but, at the same time, I must confess, that my refusals were given in such a way as not to offend; and they who, in consequence of their advances, had been exposed to them, having soon found other arrangements to make, did not shew me the less friendship. I must here add that the girls alone appeared to me thus free; while the married women on the contrary were modest and reserved. This is a characteristic difference, which distinguishes the Greater Nimiquas from the Hottentot people in general; as likewise does the low cringing air they assume when they have any thing to ask."

It has been said by Kolben, that the Nimiqua women, when they bear twins, destroy one of the infants; but Vaillant assures us that this is a falsehood, as is likewise another tale which is current in the colony. It has been said that the fathers, to shew what affection they bear their children, feed their eldest in a particular manner, as being of right the first object of paternal care. For this purpose they put him in a coop as it were; that is, they shut him up in a trench made under their hut, where, being deprived of motion, he loses little by perspiration, while they feed and cram him in a manner with milk and grease. By degrees the child fattens, and gets as round as a barrel; and when he is come to such a state as not to be able to walk, but to bend under his own weight, the parents exhibit him to the admiration of the horde; who from that period conceive more or less esteem and consideration for the family, according as the monster has acquired more or less rotundity.

Such was the account given to our author by a man who affirmed that he had been an eye witness of this mode of cramming the heir-apparent; but whenever any questions were asked on the subject of the Nimiquas themselves, the persons addressed were ready to laugh in our author's face. "Still (says he), as it appeared strange to me, that a man should talk of what he had seen, when he had in reality seen nothing; as it was possible that the fable might have some foundation, without being true in all particulars—I was willing to convince myself what could have given rise to it; and every time I visited a horde, I took care, under different pretences, to examine, one after another, all the huts of the kraal, and to ask which was the eldest child of the family: but I nowhere saw any thing that indicated either this pretended coop, or this pretended cramming." Nimiquas, Nizolius.

The Nimiquas are great cowards; yet, like the surrounding nations, they have their assagays and poisoned arrows; and, like them, can handle these arms with dexterity. They possess also those war oxen, so formidable in battle, and so favourable to the cowardice or inactivity of the combatants. They have even a peculiar implement of war, which their neighbours have not. This is a large buckler, of the height of the person who bears it, behind which the Nimiqua can completely conceal himself. But, beside that his natural apathy prevents him from giving or taking offence, he is in reality pusillanimous and cowardly from the coldness of his disposition. To utter only the name of *Houzouana* before him is sufficient to make him tremble. See HOUZOUANAS in this *Suppl.*

Notwithstanding his frigidity, the Nimiqua is not insensible to pleasure. He even seeks with avidity those which, requiring but little exertion, are capable of agitating him and procuring agreeable sensations. Their musical instruments are the same as those of the other Hottentots; but their dancing is very different, and resembles the temper of the nation. If the countenance have received from nature features that can express our passions, the body also has its attitudes and movements that paint our temper and feelings. The dance of the Nimiqua is frigid like himself, and so devoid of grace and hilarity, that, were it not for the extreme gaiety of the women, it might be called the dance of the dead.

These tortoises, to whom dancing is a fatigue, shew little eagerness for any thing but wagers, games of calculation and chance, and all the sedentary amusements which require patience and reflection, of which they are more capable than they are of motion. When our author, with great propriety, prohibited gaming in his camp, the Nimiquas, who had staid long with him, took their departure.

NITTA, a species of the MIMOSA, which flourishes on the banks of the Senegal in Africa. It is valuable to the inhabitants for its fruit, the pods of which are long and narrow, containing a few black seeds enveloped in a fine mealy powder, of a bright yellow colour, which resembles the flour of sulphur, and has a sweet mucilaginous taste. When eaten by itself it is clammy; but when mixed with milk or water, it constitutes a very pleasant and nourishing food, supplying the place of corn to the negroes.—*Park's Travels.*

NIZOLIUS (Marius), a grammarian of Italy, who by his wit and erudition contributed much to the promotion of letters in the 16th century. He published, in 1553, *Lib.* 4. *De veris Principiis et vera Ratione philoso-*

al philosophandi, contra Pseudo philosophos. In this work he attacks, with much vivacity, the schoolmen, not only for the barbarism of their terms, but for many ridiculous opinions which they held. Leibnitz was so struck with its solidity and elegance, that, to expose the obstinacy of those who were zealously attached to Aristotle, he gave a new edition of it, with critical notes of his own, 1670, in 4to. Nizolius published also, *Thesaurus Ciceronianus, sive Apparatus Linguæ Latinæ e Scriptis Tullii Ciceronis collectus*, in folio. This is a good Latin dictionary, composed of the words and expressions of Cicero; to which, it seems, Nizolius shewed as much bigotry as the schoolmen to their notions; and fell under the character of those pedants

Biog. Dictionary. whom Erasmus has ridiculed in his *Ciceronianus*. We do not find the year either of his birth or death.

NOCTURNAL ARCH, is the arch of a circle described by the sun, or a star, in the night.

Nonagesimal || Nuel. NONAGESIMAL, or NONAGESIMAL *Degree*, called also the *Mid heaven*, is the highest point, or 90th degree of the ecliptic, reckoned from its intersection with the horizon at any time; and its altitude is equal to the angle that the ecliptic makes with the horizon at their intersection, or equal to the distance of the zenith from the pole of the ecliptic. It is much used the calculation of solar eclipses.

NONAGON, a figure having nine sides and angles. In a regular nonagon, or that whose angles and sides are all equal, if each side be 1, its area will be 6·1818242 = $\frac{9}{4}$ of the tangent of 70°, to the radius 1.

NORMAL, is used sometimes for a perpendicular.

NUEL, or NEWEL, the upright post about which stairs turn, being that part of the staircase which sustains one end of the steps.

O.

Oasis || Occident. OASIS (plur. OASES), a fertile spot in the midst of a sandy desart. In the SAHARA, or Great Desart of Africa, there are many *Oases* of extreme fertility.

OBLATE, flatted or shortened; as an oblate spheroid, having its axis shorter than its middle diameter; being formed by the rotation of an ellipse about the shorter axis.

OBLIQUE ASCENSION, is that point of the equinoctial which rises with the centre of the sun, or star, or any other point of the heavens, in an oblique sphere.

OBLIQUE *Circle*, in the stereographic projection, is any circle that is oblique to the plane of projection.

OBLIQUE *Descension*, that point of the equinoctial which sets with the centre of the sun, or star, or other point of the heavens, in an oblique sphere.

OBLIQUE *Force*, or *Percussion*, or *Power*, or *Stroke*, is that made in a direction oblique to a body or plane. It is demonstrated, that the effect of such oblique force, &c. upon the body, is to an equal perpendicular one, as the sine of the angle of incidence is to radius.

OBLONG SPHEROID, is that which is formed by an ellipse revolved about its longer or transverse axis; in contradistinction from the *oblate spheroid*, or that which is flatted at its poles, being generated by the revolution of the ellipse about its conjugate or shorter axis.

OBSERVATORY, PORTABLE. See ASTRONOMY, n° 504, *Encycl.*

OCCIDENT EQUINOCTIAL, that point of the horizon where the sun sets, when he crosses the equinoctial, or enters the sign Aries or Libra.

OCCIDENT *Estival*, that point of the horizon where the sun sets at his entrance into the sign Cancer, or in our summer when the days are longest.

OCCIDENT *Hybernal*, that point of the horizon where the sun sets at midwinter, when entering the sign Capricorn.

Oct. | OCTANT, the eighth part of a circle.

ODD, in arithmetic, is said of a number that is not even. The series of odd numbers is 1, 3, 5, 7, &c.

ODDLY ODD. A number is said to be oddly odd, when an odd number measures it by an odd number. So 15 is a number oddly odd, because the odd number 3 measures it by the odd number 5.

ODOUR, that quality of certain bodies which excites the sensation of smell. In the *Annales de Chimie*, Vol. XXI. p. 254, we have a detailed account of certain experiments made by M. Benedict Prevost of Geneva, with a view to render the *emanations of odorant bodies perceptible to sight*. The account is by much too long for a work like ours; especially as we feel not ourselves inclined to attribute to the experiments all the importance which seems to have been allowed to them by the first class of the French National Institute. We shall therefore state only a few of them, which seem most to favour the author's hypothesis.

1. A concrete odorant substance, laid upon a wet glass or broad saucer, covered with a thin stratum of water, immediately causes the water to recede, so as to form a space of several inches around it.

2. Fragments of concrete odorant matter, or small morsels of paper or cork, impregnated with an odorant liquor, and wiped, being placed on the surface of water, are immediately moved by a very swift rotation. Romieu had made this observation on camphor, and erroneously attributed the effect to electricity. The motion was perceptible even in pieces of camphor of seven or eight gros.

3. An odorant liquor being poured on the water, stops the motion till it is dissipated by evaporation. Fixed oil arrests the motion for a much longer time,

Odour. and until the pellicle it forms on the water is taken off.

4. When the surface of the water is cleaned by a leaf of metal, of paper, or of glass, plunged in and withdrawn successively until the pellicle is removed, the gyratory motion is renewed. If a piece of red wax or of taper be dipped in water, and the drops shaken off into a glass of water containing odorant bodies in motion, the movement will be stopped. The same effect is not produced by metal.

5. A morsel of camphor, plunged to the depth of three or four lines in water, without floating, excites a movement of trepidation in the surrounding water, which repels small bodies in its vicinity, and carries them again to the camphor by starts The author concludes, that an elastic fluid escapes from the odorant body in the manner of the fire of a fusee or the discharge of fire arms.

6. When there is a certain proportion between the height of the water and that of the small fragment of camphor, the water is briskly driven off, returns again to the camphor, and again retires, as if by an explosion, the recoil of which often causes the camphor to make part of a revolution on its axis.

7. Camphor evaporates thirty or forty times more speedily when placed upon water, than when entirely surrounded with air.

8. Camphor, during the act of dissipation in the air, preserves its form and its opaque whiteness; upon water it is rounded, and becomes transparent as if it had undergone a kind of fusion. It may be inferred, that this arises from the acquired motion, which causes it to present a greater surface to the air.

9. When small pieces of camphor are plunged in water, the camphor becomes rounded and transparent, does not acquire any motion, and its dissipation is less perceptible than in the air. The concurrence of air and water is therefore necessary to disengage the fluid which is the cause of the motion and total dissipation of odorant bodies.

10. The motion of odorant bodies upon water decays and ceases spontaneously at the end of a certain time; because the water having then contracted a strong smell, the volatilization takes place in all the points of its surface; and the small mass being thus surrounded by the odorant fluid, which is no longer air, dissolves, as in the ordinary odorant fluids, without forming the gaseous jet which is the cause of the motion. The author compares the volatilization of the aromatic substance to a combustion excited by water.

M. Prevost hopes, that these, and other experiments which he explains, will contribute to the theory of odours, which so nearly resembles that of the gases. He does not flatter himself with having exhausted this subject, but considers his discoveries as the means of rendering odour perceptible by water, not only to the sight, but even to the touch, as are likewise the vibrations of sonorous bodies. Men deprived of the sense of smell, and even the blind according to him, may in this manner distinguish odorant bodies from those which have no smell. "Perhaps (says he) this kind of odoroscope may, by improvement, become an odorimeter. The exceptions, such for example as that of the cerumen of the ears, which produces much effect on water without being perceptibly odorant, and that of the fingers when hot or moist, are merely apparent; for if Odour. our senses do not in those cases discover odour, those of animals more powerfully energetic, such as the dog, perceive and distinguish individuals by its peculiar character. The odoroscope may afford the information which is wanting respecting these effluvia. Thus it is that the fat of game, the smell of which is nearly to us imperceptible, is very much so to dogs, and exhibits sensible marks by the odoroscope."

Professor Venturi of Modena, who heard Prevost's memoir read in the National Institute, had himself made some experiments with camphor kept separately in the air, in the water, and at the surface of the water; whence he deduces, that the most active virtue for dissolving camphor resides at that part where both the air and the water touch the camphor at the same time. Hence he explains why, in like circumstances, camphor evaporates more quickly in a moist than in a dry air; and why the Hollanders use water in their process for subliming this substance.

It might be thought that the camphor was decomposed at the surface of the water; that the water might seize the acidifying part, which renders the camphor concrete; and that the volatile part is dissipated in the atmosphere. The author rejects this notion. He thinks that water with camphor floating on its surface becomes charged with no more than a very small portion: 1. Because in these circumstances the water acquires the same taste and smell of camphor as it obtains when a small quantity of this substance is kept plunged in the same fluid. This water, by exposure to the air, loses the qualities with which it had been charged, and becomes insipid, and without smell. 2. Because when the water is saturated with all it can take up, the dissipation of the camphor continues at its surface as before. 3. Because the aerial emanations of camphor made at the surface of water do themselves crystallize into camphor.

Camphor at the surface of the water does nothing, therefore, but dissolve; and when dissolved at the ordinary temperature of the atmosphere, it is not at first in the state of vapour, as has been thought. It is simply a liquid which extends itself over the surface of water itself; and by this means coming into contact with a great surface of air, it is afterwards absorbed and evaporated. This is proved by the following facts: 1. The solution of camphor at the surface of water is more rapid in proportion to the extent of the surface. In narrow vessels, the section of the column would not be completed in ten days, even though the water might be extremely pure. 2. When the column of camphor has projecting parts, the liquid may be seen issuing by preference from certain points of the column, covering the surface of the water, and driving small floating bodies before it, in the same manner as floating bodies go and return in a bason into which the water of a canal enters with rapidity. 3. If a small piece of camphor, already wetted at one end, be brought near the edge of water contained in a broad saucer, and be made to touch the saucer itself, it deposits a visible liquor, which is oily; and by attaching itself to the saucer, destroys the adhesion between the vessel and the border of the water, so that the water retires on account of the affinity of aggregation, which not being opposed by the attraction of the saucer, causes the water to terminate in a round edge.

Odour, Œconomists.

edge. If you remove the piece of camphor, the water will not return to its place until the oily fluid is evaporated. 4. In the same manner, when the column of camphor is half immersed in the water, the oily liquor which issues forth destroys the adhesion of the water to the column, and produces a small surrounding cavity. The solution stops, or is retarded for a moment, until the fluid, extending itself over the water, becomes evaporated: the water then returns to its place, and touches the same part of the camphor; the solution begins again, and in this manner the process is effected by alternations of contact and apparent repulsion."

Of these memoirs by Prevost and Venturi, the English reader will find accurate and full translations in the first volume of *Nicholson's Philosophical Journal*, together with some judicious observations on them by the editor, which we shall take the liberty to adopt. "The philosophical consideration of odorant bodies is somewhat obscured by the old method of generalising, or referring the properties of bodies to some distinct principle or thing supposed capable of being separated from the body itself. Thus the odours of bodies have been supposed to depend on a substance imagined in a loose way to be common to them all and separable from them. Hence the terms, principle of smell, spiritus rector, and even in the modern nomenclature we find *aroma*. There does not in effect seem to be any more reason to infer the existence of a common principle of smell than of taste. The smell of ammoniac is the action of that gas upon the organ of sense; and this odorant invisible matter is exhibited to the sight when combined wit' an acid gas. But in the same manner as ammoniac emanates from water, and leaves most part of that fluid behind, so will the volatile parts of bodies be most eminently productive of this action; and very few, if any, natural bodies will be found which rise totally. The most striking circumstance in the effect is, that an act of such power should be attended with a loss by exhalation which is scarcely to be appreciated by weight, or in any other method during a short interval of time. But we know so little of nervous action, and of other phenomena of electricity, of galvanism (See GALVANISM in this *Suppl.*), or even of heat, which strongly affect the senses, but elude admeasurement by gravitation, that the difficulty of weighing the effluvia of odorant bodies becomes less astonishing."

ŒCONOMISTS, a sect of philosophers in France, who have made a great noise in Europe, and are generally believed to have been unfriendly to religion. The founder of this sect was a *Dr Duquesnai*, who had so well insinuated himself into the favour of Louis XV. that the king used to call him his *thinker*. The sect was called *œconomists*, because the œconomy and order to be introduced into the finances, and other means of alleviating the distresses of the people, were perpetually in their mouths. The Abbé Barruel admits, that there may have been some few of them who directed their speculations to no other object; but he brings very sufficient proof that the great aim of the majority of the sect was to eradicate from the minds of the people 'l reverence for divine revelation.

"Duquesnai (says he) and his adepts had more especially undertaken to persuade their readers, that the country people, and mechanics in towns, were entirely destitute of that kind of instruction necessary for their professions; that men of this class, unable to acquire knowledge by reading, pined away in an ignorance equally fatal to themselves and to the state; that it was necessary to establish free schools, and particularly throughout the country, where children might be brought up to different trades, and instructed in the principles of agriculture. D'Alembert, and the Voltairean adepts, soon perceived the advantages they could reap from these establishments. In union with the œconomists, they presented various memorials to Louis XV. in which not only the temporal but even the spiritual advantages of such establishments for the people are strongly urged. The king, who really loved the people, embraced the project with warmth. He opened his mind on the subject to Mr Bertin, whom he honoured with his confidence, and had entrusted with h purse;" and it was with great difficulty that this minister could convince him of the dangerous designs of the sect.

"Determined (says he) to give the king proof that the œconomists imp upon him. I ought to gain the confidence of those pedla ho travel through the country, and expose their goods to sale in the villages, and at the gates of country seats I suspected those in particular who dealt in books to be nothing less than the agents of philosophism with the good country folks. In my excursions into the country I fixed my attention above all on the latter. When they offered me a book to buy, I questioned them what might be the books they had? Probably catechisms or prayer-books? Few others are read in the villages? At these words I have seen many smile. No, they answered, those are not our works; we make much more money of Voltaire, Diderot, and other philosophic writings. What! said I; the country people buy Voltaire and Diderot? Where do they find the money for such dear works? Their constant answer was, we have them at a much cheaper rate than prayer-books; we can sell them at ten sols (5d.) a volume, and have a pretty profit into the bargain. Questioning some of them still farther, many of them owned that those books cost them nothing; that they received whole bales of them without knowing whence they came, but being simply desired to sell them in their journeys at the lowest price."

"Louis XV. warned by the discovery made by his minister, was at length satisfied that the establishment of these schools, so much urged by the conspirators, would only be a new instrument of seduction in their hands. He abandoned the plan; but, perpetually harassed by the protecting sophisters, he did not strike at the root of the evil, and but feebly impeded its progress. The pedlars continued to promote the measures of the conspirators; yet this was but one of the inferior means employed to supply the want of their free schools, as a new discovery brought to light one far more fatal.

"About the middle of the month of September 1789, little more than a fortnight antecedent to the atrocious 5th and 6th of October, at a time when the conduct of the National Assembly, having thrown the people into all the horrors of a revolution, indicated that they would set no bounds to their pretensions, Mr Le Roy, lieutenant of the King's Hunt, and an academician, being at dinner at the house of Mr D'Angevilliers, intendant of the buildings of his majesty, the

conversation turned on the disasters of the revolution, and on those that were too clearly to be foreseen. Dinner over, the nobleman above mentioned, a friend of Le Roy, hurt at having seen him so great an admirer of the sophisters, reproached him with it in the following expressive words: *Well! this, then, is the work of Philosophy!* Thunderstruck at these words—Alas! cried the academician, *to whom do you say so? I know it but too well, and I shall die of grief and remorse!* At the word *remorse*, the same nobleman questioned him whether he had so greatly contributed towards the revolution as to upbraid himself with it in that violent manner? 'Yes (answered he), I have contributed to it, and far more than I was aware of. I was secretary to the committee to which you are indebted for it; but I call heaven to witness, that I never thought it would go to such lengths. You have seen me in the king's service, and you know that I love his person. I little thought of bringing his subjects to this pitch, *and I shall die of grief and remorse!*'

"Pressed to explain what he meant by this committee, this secret society, entirely new to the whole company, the academician returned: 'This society was a sort of club that we philosophers had formed among us, and only admitted into it persons on whom we could perfectly rely. Our sittings were regularly held at the Baron D'Holbach's. Lest our object should be surmised, we called ourselves œconomists. We created Voltaire, though absent, our honorary and perpetual president. Our principal members were D'Alembert, Turgot, Condorcet, Diderot, La Harpe, and that Lamoignon, keeper of the seals, who on his dismission shot himself in his park.'

"The whole of this declaration was accompanied with tears and sighs; when the adept, deeply penitent, continued: 'The following were our occupations; the most of those works which have appeared for this long time past against religion, morals, and government, were ours, or those of authors devoted to us. They were all composed by the members or by the orders of the society. Before they were sent to the press, they were delivered in at our office. There we revised and corrected them; added to, or curtailed them, according as circumstances required. When our philosophy was too glaring for the times, or for the object of the work, we brought it to a lower tint; and when we thought that we might be more daring than the author, we spoke more openly. In a word, we made our writers say exactly what we pleased. Then the work was published under the title or name we had chosen, the better to hide the hand whence it came. Many, supposed to have been posthumous works, such as *Christianity Unmasked*, and divers others *attributed to Freret and Boulanger* after their deaths, were issued from our society.

'When we had approved of those works, we began by printing them on fine or ordinary paper, in sufficient number to pay our expences, and then an immense number on the commonest paper. These latter we sent to hawkers and booksellers free of cost, or nearly so, who were to circulate them among the people at the lowest rate. These were the means used to pervert the people, and bring them to the state you now see them in. I shall not see them long, *for I shall die of grief and remorse!*'

This recital is too well authenticated to be called in question, and too plain to need a commentary. Let it be a warning against all secret societies, by whatever title of benevolence they may be designed by those who form them.

OIL MILL, a mill for expressing the oils from fruits, or grains, &c. As these kingdoms do not produce the olive, it would be needless to describe the mills which are employed in the southern parts of Europe. We shall content ourselves, therefore, with a description of a Dutch oil mill, employed for grinding and pressing lintseed, rape seed, and other oleaginous grains. Farther, to accommodate our description still more to our local circumstances, we shall employ water as the first mover, thus avoiding the enormous expence and complication of a windmill. Oil.

In Plate XXXVIII. fig. A,

1. Is the elevation of a wheel, over or undershot, as the situation may require.

2. The bell metal socket, supported by masonry, for receiving the outer gudgeon of the water wheel.

3. The water course.

Fig. B.

1. A spur wheel upon the same axis, having 52 teeth.

2. The trundle that is driven by N° 1. and has 78 staves.

3. The *wallower*, or axis for raising the pestles. It is furnished round its circumference with *wipers* for lifting the *pestles*, so that each may fall twice during one turn of the water wheel, that is, three *wipers* for each pestle.

4. A frame of timber, carrying a concave half cylinder of bell-metal, in which the wallower (cased in that part with iron plates) rests and turns round. It will be seen in profile, fig. G.

5. Masonry supporting the inner gudgeon of the water wheel and the above-mentioned frame.

6. Gudgeon of the wallower, which bears against a bell metal step fixed in the wall. This double support of the wallower is found to be necessary in all mills which drive a number of heavy stampers.

Fig. C, Is the elevation of the pestle and press-frame, their furniture, the mortars, and the press-pestles.

1. The six pestles.

2. Cross pieces between the two rails of the frame, forming, with these rails, guides for the perpendicular motion of the pestles.

3. The two rails. The back one is not seen. They are checked and bolted into the standards N° 12.

4. The tails of the *lifts*, corresponding to the wipers upon the wallower.

5. Another rail in front, for carrying the *detents* which hold up the pestles when not acting. It is marked 14 in fig. M.

6. A beam a little way behind the pestles. To this are fixed the pulleys for the ropes which lift and stop the pestles. It is represented by 16 in fig. M.

7. The said pulleys with their ropes.

8. The *driver*, which strikes the wedge that presses the oil.

9. The *discharger*, a stamper which strikes upon the inverted wedge, and loosens the press.

10.

Oil 10. The lower rail with its cross pieces, forming the lower ... of the pe"

11. A small cog wheel upon the wallower, for turning the *spatula*, which stirs about the oil-seed in the *chauffer pan*. It has 28 teeth, and is marked N° 6 in fig. M.

12. The four standards, mortised below into the *block*, and above into the joists and beams of the building

13. The six *mortars* hollowed out of the block itself, and in shape pretty much like a kitchen pot.

14. The feet of the pestles rounded into cylinders, and shod with a great lump of iron.

15. A board behind the pestles, standing on its edge, but inclining a little backwards. There is such another in front, but not represented here. These form a sort of trough, which prevents the seed from being scattered about by the fall of the pestles, and lost

16. The first *press-box* (also hollowed out of the block), in which the grain is squeezed, after it has come for the first time from below the millstones.

17. The second *press-box*, at the other end of the block, for squeezing the grain after it has passed a second time under the pestles.

18. Frame of timber for supporting the other end of the wallower, in the same manner as at N° 4 fig B.

19. Small cog wheel on the end of the wallower for giving motion to the millstones. It has 28 teeth.

20. Gudgeon of the wallower, bearing on a bell metal socket fixed in the wall.

21. Vessels for receiving the oil from the press-boxes.

22. Joists supporting the block.

Fig. D. Elevation and mechanism of the millstones.

1. *Upright shaft*, carrying the great cog wheel above, and the *runner millstones* below in their frame.

2. Cog-wheel of 76 cogs, driven by N° 19. of fig C.

3. The frame of the *runners*. This will be more distinctly understood in N° 4. fig. H.

4. The innermost runner, or the one nearest the shaft.

5. Outermost ditto, being farther from the shaft.

6. The *inner rake*, which collects the grain under the outer runner.

7. The *outer rake*, which collects the grain under the inner runner. In this manner the grain is always turned over and over, and crushed in every direction. The inner rake lays the grain in a slope, of which fig. O. is a section; the runner flattens it, and the second rake lifts it again, as is marked in fig P; so that every side of a grain is presented to the millstone, and the rest of the *ligger* or *nether millstone* is so swept by them, that not a single grain is left on any part of it. The outer rake is also furnished with a rag of cloth, which rubs against the border or hoop that surrounds the nether millstone, so as to drag out the few grains which might otherwise remain in the corner.

8. The ends of the iron axle which passes through the upright shaft, and through the two runners. Thus they have two motions: 1*mo*, A rotation round their own axis. 2*do*. That by which they are carried round upon the nether millstone on which they roll. The holes in these millstones are made a little widish; and the holes in the ears of the frame, which carry the ends of the iron axis, are made oval up and down. This great freedom of motion is necessary for the runner millstones, because frequently more or less of the grain is below them at a time, and they must therefore be at liberty to get over it without straining, and perhaps breaking, the shaft.

9. The ears of the frame which lead the two extremities of the iron axis. They are mortised into the under side of the bars of the square frame, that is carried round with the shaft.

10. The border or hoop which surrounds the nether millstone.

11. and 12. The nether millstone and masonry which supports it.

Fig. E. Form of the wallower, shewing the disposition of the wipers along its surface

1. Two parts of this shaft, which are nicely rounded, and fortified with iron plates, and which rest upon the bell metal concaves, which are represented in n° 4. of fig. C.

2. The little wheels at each end, for giving motion to the two spatulæ, marked n° 11. fig. C.

3. The wipers for the second press.

4. The wipers for the first press.

5. The wipers for the six pestles.

Fig. F. Represents the surface of the wallower unfolded into a rectangular parallelogram, in order to shew the distribution of the wipers, and consequently the succession of the strokes given by the different pestles. This distribution has something peculiar Each pestle has three wipers; and there are also three for the driver and discharger of the second press. The driver and wiper of the first press have but one and a half; one for the driver, and the half for the discharger; so that it strikes twice, and the driver only once, in a turn of the shaft. This is the Dutch practice, which differs from that of Flanders. The succession of the strokes may be conceived as follows: Reckon the stampers, including those of the presses, from the water wheel toward the other end of the wallower, and calling them *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, *i*, *k*, and supposing that *a* makes the first stroke, they proceed in the following order for one turn of the wallower:

ab, *d*, *f*, *h*, *c*, *e*, *g*, *ab*, *d*, *f*, *h*, *c*, *e*, *g*, *ab*, *d*, *f*, *i*, *k*, *c*, *e*, *g*.

Here it may be observed that *a* and *b* strike together. They would do so if allowed; but one of them is held up by its detent till the workman sees proper to disengage it. Each pestle, and the driver and discharger of the second press, makes three strokes for one turn of the wallower. But the driver *k* of the first press makes only one stroke in that time, namely, in the interval between the last strokes of *e* and *g*. The discharger *i* of this press makes two strokes; one of them in this same interval, and the other along with the first stroke of *c*. The second pressing requires a much more violent pressure than the first, because the cake must be left perfectly dry and hard.

Fig. G. Profile of the frame of timber which carries the wallower, and greatly contributes to render its motion steady.

Fig. H. Is a view of one of the millstones.

1. The nether millstones, and the masonry supporting the whole.

2. The runner.

3. A

3. A fort of cafe which enclofes the two wings of the millftone at a very fmall diftance from it, in order to prevent the grain which fticks to it from being fcattered. There is another method practifed at fome mills.

Fig. I. Reprefents that of Sardamm. AA are two iron rods, about half an inch fquare, hanging on the axle, on each fide of the millftone. Thefe rods are joined by a crofs piece C, which almoft touches the millftone. A piece of leather is put between, which rubs upon the millftone, and clears it of the grain which chances to ftick to it. N° 4. and 6. reprefent the ears of this frame, by which the end of the iron axle is fupported, and carried round by the upright fhaft n° 5.

Fig. K. Plan of the runner millftones, and the frame which carries them round.

1, 1. Are the two millftones.

3, 3, 3, 3 The outfide pieces of the frame.

4, 4, 4, 4. The crofs bars of the frame which embrace the upright fhaft 5, and give motion to the whole.

6, 6. The iron axis upon which the runners turn.

7. The outer rake.

8. The inner ditto.

Fig. L. Reprefents the nether millftone feen from above.

1. The wooden gutter, which furrounds the nether millftone.

2. The border or hoop, about fix inches high, all round, to prevent any feed from being fcattered

3. An opening or trap door in the gutter, which can be opened or fhut at pleafure. When open, it allows the bruifed grain, collected in and fhoved along the gutter by the rakes, to pafs through into troughs placed below to receive it.

4. Portion of the circle defcribed by the outer runner.

5. Portion of the circle defcribed by the inner one. By thefe we fee that the two ftones have different routes round the axis, and bruife more feed.

6. The outer rake.

7. The inner ditto.

8. The fweep, making part of the inner rake, occafionally let down for fweeping off all the feed when it has been fufficiently bruifed. The preffure and action of thefe rakes is adjufted by means of wooden fprings, which cannot be eafily and diftinctly reprefented by any figure. The oblique pofition of the rakes (the outer point going foremoft) caufes them to fhove the grain inwards or toward the centre, and at the fame time to turn it over, fomewhat in the fame manner as the mould-board of a plough fhoves the earth to the right hand, and partly turns it over. Some mills have but one fweeper; and, indeed, there is great variety in the form and conftruction of this part of the machinery.

Fig. M. Profile of the peftle frame.

1. Section of the horizontal fhaft

2. Three wipers for lifting the peftles.

3. Little wheel of 28 teeth for giving motion to the fpatula.

4. Another wheel, which is driven by it, having 20 teeth.

5. Horizontal axle of ditto.

6. Another wheel on the fame axle, having 13 teeth.

7. A wheel upon the upper end of the fpindle, having 12 teeth.

8. Two guides, in which the fpindle turns freely, and fo that it can be fhifted higher and lower.

9. A lever, moveable round the piece n° 14. and having a hole in it at 9, through which the fpindle paffes, turning freely. The fpindle has in this place a fhoulder, which refts on the border of the hole 9; fo that by the motion of this lever the fpindle may be difengaged from the wheel work at pleafure. This motion is given to it by means of the lever 10, 10, moveable round its middle. The workman employed at the chauffer pulls at the rope 10, 11, and thus difengages the fpindle and fpatula.

11. A peftle feen fidewife.

12. The *lift* of ditto.

13. The upper rails, marked n° 3. in fig. C.

14. The rail, marked n° 5. in fig. C. To this are fixed the detents, which ferve to ftop and hold up the peftles.

15. A detent, which is moved by the rope at its outer end.

16. A bracket behind the peftles, having a pulley, through which paffes the rope going to the detent 15.

17. The faid pulley.

18. The rope at the workman's hand, paffing through the pulley 17, and fixed to the end of the detent 15.

This detent naturally hangs perpendicular by its own weight. When the workman wants to ftop a peftle, he pulls at the rope 18, during the rife of the peftle. When this is at its greateft height, the detent is horizontal, and prevents the peftle from falling by means of a pin projecting from the fide of the peftle, which refts upon the detent, the detent itfelf being held in that pofition by hitching the loop of the rope upon a pin at the workman's hand.

19. The two lower rails, marked n° 10. fig. C.

20. *Great* wooden, and fometimes ftone, *block*, in which the mortars are formed, marked n° 21. in fig. C.

21. Veffel placed below the prefs boxes for receiving the oil.

22. Chauffer, or little furnace, for warming the bruifed grain.

23. Backet in the front of the chauffer, tapering downwards, and opening below in a narrow flit. The hair bags in which the grain is to be preffed after it has been warmed in the chauffer, are filled by placing them in this backet. The grain is lifted out of the chauffer with a ladle, and put into thefe bags; and a good quantity of oil runs from it through the flit at the bottom into a veffel fet to receive it.

24. The fpatula attached to the lower end of the fpindle, and turning round among the grain in the chauffer-pan, and thus preventing it from fticking to the bottom or fides, and getting too much heat.

Fig. N. Plan of part of the works.

1, 1. Furnaces for warming the grain.

2, 2. The backets for holding the facks while they are a-filling.

3, 3. The pan in which the bruifed grain is heated by the chauffer.

4, 4. A trough for receiving the chips, into which the preffed oil cakes are cut, to be afterwards put into the pan and warmed.

5. The prefs-box for the fecond preffing.

6. The prefs-box for the firft preffing.

7. The fix mortars.

8. The floping boards, to hinder the fcattering of the oil feed.

9. The

9. The nether milſtone, but out of its place.

10. Its centre a little higher than the reſt.

11. A rib of wood going round the edge of the nether milſtone, and even with its ſurface, but riſing a very little outwards, and ſurrounded with a border or hoop about an inch high, to prevent the ſeed from being ſcattered on the ground.

Fig. Q. A ſection, lengthwiſe, of the great block, with the mortars and preſs-boxes.

1. The ſix peſtles.

2. The ſix mortars, each of which has an iron plate at its bottom.

3. The *driving* ſtamper, which falls on the wedge of the firſt preſſing.

4. Ditto, for the ſecond ditto.

5. The *diſcharger*, which ſtrikes on the inverted wedge in order to free the preſs.

6. Ditto, for the ſecond preſſing.

7. Wedge for freeing the preſs.

8. Wedge for preſſing.

9. Wooden *cheeks*, two inches thick, which are placed between the middle wedge and the *ſliding wedges* on each ſide.

10. Preſs-irons, between which are placed the hair-bags containing the bruiſed grain.

11. Iron plate, called the *fountain*, at the bottom, pierced with holes, correſponding with a hole in the block, for allowing the oil to run off from the preſſed grain.

12. Veſſel for receiving ditto.

13. A long iron plate at the bottom of the preſs box, under the drawing and diſcharging wedges.

Fig. R. Another view of the preſs-irons.

1. The ſide-irons laid flat.

2. The ſame ſeen edgewiſe.

3. The pierced iron plate, upon which the two irons, n° 1. ſtand upright, with the hair-bag between them.

4. One of the hair-bags. It may be obſerved that the ſeams of theſe bags are made on the flat ſides, and not on the edges, where they would be in danger of burſting.

5. A long hair-cloth, in which the bag is wrapped before it is ſet into the preſs. The bag, being filled with bruiſed grain, is placed with its bottom at *a*, and the top at *b*; the part *c a* is lapped over it, reaching to *b*, and then the other end *d* is lapped over that, and reaches to *a*, and the loop at its end ſerves as a handle by which to lift it, and place it properly between the preſs-irons.

Fig. S. The principal pieces of the preſs.

1. The wooden cheeks.

2. The diſcharging wedge.

3. The driving wedge.

4 and 5. The ſliding blocks, which tranſmit the preſſure produced by the driving wedge.

The foregoing enumeration and views of the different parts of a Dutch oil-mill, are ſufficient, we imagine, to enable an intelligent mill-wright, to whom the machine is altogether new, to underſtand its manner of working, and its adaptation to the various parts of the proceſs for extracting the oil from ſeeds or kernels. It would require a very minute deſcription indeed to explain it to a perſon altogether unacquainted with mill-work.

The firſt part of the proceſs is bruiſing the ſeed under the runner ſtones (A). That this may be more expeditiouſly done, one of the runners is ſet about ⅔ds of its own thickneſs nearer the ſhaft than the other. Thus they have different treads; and the grain, which is a little heaped towards the centre, is thus bruiſed by both. The inner rake gathers it up under the outer ſtone into a ridge, of which the ſection is repreſented in Plate XL. fig. O. The ſtone paſſes over it and flattens it. It is gathered up again into a ridge, of the form of fig. P. under the inner ſtone, by the outer rake, which conſiſts of two parts. The outer part preſſes cloſe on the wooden border which ſurrounds the nether ſtone, and ſhoves the ſeed obliquely inwards, while the inner part of this rake gathers up what had ſpread toward the centre. The other rake has a joint near the middle of its length, by which the outer half of it can be raiſed from the nether ſtone, while the inner half continues preſſing on it, and thus ſcrapes off the moiſt paſte. When the ſeed is ſufficiently bruiſed, the miller lets down the outer end of the rake. This immediately gathers the whole paſte, and ſhoves it obliquely outwards to the wooden rim, where it is at laſt brought to a part that is left unboarded, and it falls through into troughs placed to receive it. Theſe troughs have holes in the bottom, through which the oil drips all the time of the operation. This part of the oil is directed into a particular ciſtern, being conſidered as the pureſt of the whole, having been obtained, without preſſure, by the mere breaking of the hull of the ſeed.

In ſome mills this operation is expedited, and a much greater quantity of this beſt oil is obtained, by having the bed of maſonry which ſupports the legger formed into a little furnace, and gently heated. But the utmoſt care is neceſſary to prevent the heat from becoming conſiderable. This, enabling the oil to diſſolve more of the fermentable ſubſtance of the ſeed, expoſes the oil to the riſk of growing ſoon very rancid; and, in general, it is thought a hazardous practice, and the oil does not bring ſo high a price.

When the paſte comes from under the ſtones, it is put into the hair bags, and ſubjected to the firſt preſſing. The oil thus obtained is alſo eſteemed as of the firſt quality, ſcarcely inferior to the former, and is kept apart (The great oil ciſtern being divided into ſeveral portions by partitions).

The oil cakes of this preſſing are taken out of the bags, broken to pieces, and put into the mortars for the firſt *ſtamping*. Here the paſte is again broken down, and the parenchyma of the ſeed reduced to a fine meal. Thus free egreſs is allowed to the oil from every veſicle in which it was contained. But it is now rendered much more clammy, by the forcible mixture of the mucilage,

(A) We are told, that in a mill at Reichenhoffen in Alſace, a conſiderable improvement has been made by paſſing the ſeed between two ſmall iron rollers, before it is put under the milſtones. A great deal of work is ſaid to be ſaved by this preliminary operation, and finer oil produced, which we think very probable. The ſtamping and preſſing go on as in other mills.

ciiage, and even of the finer parts of the meal. When sufficiently pounded, the workman stops the pestle of a mortar, when at the top of its lift, and carries the contents of the mortar to the first chauffer pan, where it is heated to about the temperature of melting bees wax (this, we are told, is the test), and all the while stirred about by the spatula. From thence it is again put into hair bags, in the manner already described; and the oil which drips from it during this operation is considered as the best of the second quality, and in some mills is kept apart. The paste is now subjected to the second pressing, and the oil is that of the second quality.

All this operation of pounding and heating is performed by one workman, who has constant employment by taking the four mortars in succession. The putting into the bags and conducting of the pressing gives equal employment to another workman.

In the mills of Piccardy, Alsace, and most of Flanders, the operation ends here; and the produce from the chauffer is increased, by putting a spoonful or two of water into the pan among the paste.

But the Dutch take more pains. They add no water to the paste of this their *first stamping*. They say that this greatly lowers the quality of the oil. The cakes which result from this pressing, and are there sold as food for cattle, are still fat and softish. The Dutch break them down, and subject them to the pestles for the *second stamping*. These reduce them to an impalpable paste, stiff like clay. It is lifted out, and put into the *second* chauffer pan, a few spoonfuls of water are added, and the whole kept for some time as hot as boiling water, and carefully stirred all the while. From thence it is lifted into the hare bags of the last press, subjected to the press; and a quantity of oil, of the lowest quality, is obtained, sufficient for giving a satisfactory profit to the miller. The cake is now perfectly dry, and hard, like a piece of board, and is sold to the farmers. Nay, there are small mills in Holland, which have no other employment than extracting the oil from the cakes which they purchase from the French and Brabanters; a clear indication of the superiority of the Dutch practice.

The nicety with which that industrious people conduct all their business is remarkable in this manufacture.

In their oil cistern the parenchymous part, which unavoidably gets through, in some degree, in every operation, gradually subsides, and the liquor, in any division of the cistern, comes to consist of strata of different degrees of purity. The pumps which lift it out of each division are in pairs; one takes it up from the very bottom, and the other only from half depth. The last only is barrelled up for the market, and the other goes into a deep and narrow cistern, where the dreg again subsides, and more pure oil of that quality is obtained. By such careful and judicious practices, the Dutch not only supply themselves with this important article, but annually send considerable quantities into the very provinces of France and Flanders where they bought the seed from which it was extracted. When we reflect on the high price of labour in Holland, on the want of timber for machinery, on the expence of building in that country, and on the enormous expence of wind mill machinery, both in the first erection and the subsequent wear and tear, it must be evident, that oil mills erected in England on water falls, and after the Dutch manner, cannot fail of being a great national advantage. The chatellanie or seigneurie of Lille alone makes annually between 30,000 and 40,000 barrels, each containing about 26 gallons.

What is here delivered is only a sketch. Every person acquainted with machinery will understand the general movements and operations. But the intelligent mechanic well knows, that operations of this kind have many minute circumstances which cannot be described, and which, nevertheless, may have a great influence on the whole. The rakes in the bruising-mill have an office to perform which resembles that of the hand, directed by a careful eye and unceasing attention. Words cannot communicate a clear notion of this; and a mill, constructed from the best drawings, by the most skilful workman, may gather the seed so ill, that the half of it shall not be bruised after many rounds of the machinery. This produces a scanty return of the finest oil; and the mill gets a bad character. The proprietor loses his money, is discouraged, and gives up the work.—There is no security but by procuring a Dutch millwright, and paying him with the liberality of Britons. Such unhoped-for tasks have been performed of late years by machinery; and mechanical knowledge and *invention* is now so generally diffused, that it is highly probable that we should soon excel our teachers in this branch But this very diffusion of knowledge, by encouraging speculation among the artists, makes it a still greater risk to erect a Dutch oil-mill without having a Dutchman, acquainted with its most improved present form, to conduct the work. We do our duty in giving this counsel.

OKU-JESSO. See SEGALIEN in this *Suppl.*

OMPHALOPTER, or OMPHALOPTIC, in optics, a glass that is convex on both sides, popularly called a *convex lens*.

ONISCUS (See *Encycl.*). Two new species of this genus of insects were discovered by *La Martiniere*, the naturalist who accompanied Perouse on his last voyage of discovery. For the information of such of our readers as are entomologists, we shall give the author's description of these species. Of the first, which he says only *nearly* answers to the *generic* character of oniscus, E (fig. 1.) is a view of the upper part of its body, and at F of the lower. Its body is crustaceous, and of an opaque white, with two round rust-coloured spots on the anterior part of its corslet; two others, much larger, in the form of a crescent, are on the *elytræ*; its shield is also of the same colour. The under part of the thorax is furnished with four pair of legs; the first and third of which are terminated with sharp claws; the second, from its form, serves it to swim with; the fourth is very small, consisting of two membranaceous threads. Some scales, also membranaceous and very channelled, may also perform the office of legs; of these the two lower are the largest. Its belly is filled with vermicular intestines of the size of a hair; its mouth is placed between the first and second pair of legs, and is of the form of a small trunk placed between two lips, joined only at the upper extremity.

Plate XXXII.

Fig. 2. represents an insect of the genus *oniscus Linn.* Its body is nearly of the form, consistence, and colour, of the *oniscus asellus*, except that it is not divided

vided by ſegments as this laſt is. It has a double tail three times as long as the body; from the inſertion of which, at the hinder part of the body, ſpring two legs, uſed chiefly by the animal in ſwimming upon its back. The inſect, viewed on the lower part H, preſents ſix pair of legs: the two firſt of which terminate in very ſharp and thick points; it makes uſe of the third to ſwim with, and to balance its body, together with that pair which is inſerted at the baſe of the tail; the fourth pair, and the largeſt of all, is armed with two very ſharp points, which the animal forces into the body of any fiſh on which it ſeizes; the two laſt pair are nothing more than very finely divided membranes. Between the two firſt is ſituated its trunk, ſmooth, and about half a line long; at the baſe of the third pair are two points, of a horny conſiſtence, very hard, and firmly fixed. The two horns alſo below the large pair of legs are, in like manner, very firmly united to its body. Martiniere imagines it to be by means of theſe darts that it pierces the body of the fiſh on which it is found, and that then, changing its ſituation, it finds means to introduce its trunk into the holes thus formed. When put into a glaſs it ſinks to the bottom, and riſes again to the ſurface with the greateſt eaſe, advancing with the edge of its body, and deſcribing curves. Its two long tails are very eaſily pulled off, without the animal appearing to ſuffer any pain.

OPAQUE, not tranſlucent, nor tranſparent, or not admitting a free paſſage to the rays of light.

OPARO or Oparro, the name given by Captain Vancouver to a ſmall iſland which he diſcovered in latitude 27° 36′ ſouth, and in longitude 215° 49′ eaſt from Greenwich. It was eſtimated at about 6½ miles in length, and no other land was in ſight. Its principal character is a cluſter of high craggy mountains, forming, in ſeveral places, moſt romantic pinnacles, with perpendicular cliffs nearly from their ſummits to the ſea: the vacancies between the mountains would more properly be termed chaſms than valleys. The tops of ſix of the higheſt hills bore the appearance of fortified places, reſembling redoubts; having a ſort of blockhouſe, in the ſhape of an Engliſh glaſs-houſe, in the centre of each, with rows of palliſadoes a conſiderable way down the ſides of the hills, nearly at equal diſtances. Theſe overhanging, ſeemed intended for advanced works, and apparently capable of defending the citadel by a few againſt a numerous hoſt of aſſailants. On all of them people were noticed as if on duty, conſtantly moving about. What we conſidered (ſays the author) as block-houſes, from their great ſimilarity in appearance to that ſort of building, were ſufficiently large to lodge a conſiderable number of perſons, and were the only habitations we ſaw. Yet, from the number of canoes that in ſo ſhort a time aſſembled round the Engliſh ſhip, it is natural to conclude, that the inhabitants are very frequently afloat; and to infer, that the ſhores, and not thoſe fortified hills which appeared to be in the centre of the iſland, would be preferred for their general reſidence.

Whether the fortified places here deſcribed were intended for defences of the iſlanders againſt each other, or againſt attacks from ſome more powerful neighbours, could only be conjectured; but the latter idea ſeems the moſt probable. From the language of the people, and their reſemblance to the Friendly iſlanders, Captain Vancouver conſiders them all as having ſprung from the ſame original ſtock. The people of Oparo, however, are diſtinguiſhed by two circumſtances, certainly in their favour. Not one of them was tattowed; and though they appeared not to have ever ſeen a European before, they all ſeemed perfectly well acquainted with the uſes to which they could apply iron, and preferred articles of it to looking glaſſes, beads, and other trinkets, with which ſavages are uſually delighted. Though there appeared to be anchoring ground near the north weſt end of the iſland, circumſtances rendered it inconvenient for Captain Vancouver to land on it, ſo that we are yet in a great meaſure ſtrangers to the diſpoſitions of the people, though they appeared to be hoſpitable.

OPEN Flank, in fortification, is that part of the flank which is covered by the orillon or ſhoulder.

OPENING *of the Trenches*, is the firſt breaking of ground by the beſiegers, in order to carry on their approaches towards a place.

OPERA Glass, is a diagonal perſpective, of which the following conciſe and perſpicuous deſcription is taken from Dr Hutton's Mathematical Dictionary.— ABCD (Plate XLI) repreſents a tube about four inches long; in each ſide of which there is a hole EF and GH, exactly againſt the middle of a plane mirror IK, which reflects the rays falling upon it to the convex glaſs LM; through which they are refracted to the concave eye-glaſs NO, whence they emerge parallel to the eye at the hole *r s*, in the end of the tube. Let P *a* Q be an object to be viewed, from which proceed the rays P *c*, *a b*, and Q *d*: theſe rays, being reflected by the plane mirror IK, will ſhew the object in the direction *c p*, *b a*, *d q*, in the image *p q*, equal to the object PQ, and as far behind the mirror as the object is before it: the mirror being placed ſo as to make an angle of 45 degrees with the ſides of the tube. And as, in viewing near objects, it is not neceſſary to magnify them, the focal diſtances of both the glaſſes may be nearly equal; or, if that of LM be three inches, and that of NO one inch, the diſtance between them will be but two inches, and the object will be magnified three times, being ſufficient for the purpoſes to which this glaſs is applied.

When the object is very near, as XY, it is viewed through a hole *x y*, at the other end of the tube AB, without an eye-glaſs; the upper part of the mirror being poliſhed for that purpoſe as well as the under. The tube unſcrews near the object-glaſs LM, for taking out and cleanſing the glaſſes and mirror. The poſition of the object will be erect through the concave eye-glaſs.

The peculiar artifice of this glaſs is to view a perſon at a ſmall diſtance, ſo that no one ſhall know who is obſerved; for the inſtrument points to a different object from that which is viewed; and as there is a hole on each ſide, it is impoſſible to know on which hand the object is ſituated which you are viewing. It is chiefly uſed in play houſes; and hence its name: but we have ſeen it moſt indecently employed by thoſe who ſhould have ſet a better example, even in a cathedral church!

OPHRYS (See *Encycl.*). A new ſpecies of this plant has been lately deſcribed in the *Annual Hampſhire Repoſitory*, by a Fellow of the Linnean Society in the following words:

" *Stem*—about 12 inches high, erect, [illegible]

culate,

culate, pubescent at the upper genicles. *Spike*—strictly spiral, flowers spirally ascending, about 24, brightly white. Upper petal ovato acuminate, pubescent, lightly ciliate, straight. Two middle *petals* oblong-recurved. Two lower *petals* oblong acuminate, lightly ciliate only on the lower side near the base, projecting like elephant's tusks. *Nectary*, broad, recurved, ragged, bicipitate. *Leaves floral*—carinate acuminate, ciliate reaching and pointing to the middle of the flowers. *Leaves radical*—five or six, about six inches long, narrow, attenuate both ways, acuminate, the lower more hastate. *Leaves cauline*—lanceolate, alternate.

"Observation.—This plant has much the habit, as well as autumnal florescence, of Oriental spiralis, and is so perfectly spiral also, that the specific name of the other should be altered, as being no longer exclusively spiral; at the same time that a specific name should be given to this: neither of which (says the author) I shall presume to do, but shall suggest it to the Linnean Society, of which I have the honour to be a Fellow."—This ophrys flowered, for the first time, it is believed, in England, in Hampshire, October 1796.

OPHIUCUS, a constellation of the northern hemisphere; called also *Serpentarius*.

OPIUM (See *Encycl.*), is a medicine of such intrinsic value, and of so high a price, that every method which promises to increase the quantity in the market must be of importance. It was therefore, with much propriety, that *the Society for the Encouragement of Arts, &c.* some time ago, voted 50 guineas to Mr John Ball of Williton, Somersetshire, for the discovery of his method of preparing opium from poppies of the growth of England. The poppies, which he recommends as the most productive, are the *double* or *semi-double*, of a dark colour; the seeds of which he advises to be sown the latter end of February, and again about the second week in March, in beds three feet and a half wide (well prepared with good rotten dung, and often turned or ploughed, in order to mix it well, and have it fine), either in small drills, three in each bed, in the manner sallads are sown, and when about two inches high, to thin them one foot apart; or otherwise, to sow them in beds, in the broad-cast way, and thin them to the same distance. If they be kept free from weeds, they will grow well, and will produce from four to ten heads, shewing large and different coloured flowers; and when their leaves die away, and drop off, the pods then being in a green state, is the proper time for extracting the opium, by making such longitudinal incisions as are, for this purpose, made in the east (See OPIUM and PAPAVER, *Encycl.*). Immediately on the incision being made, a milky fluid will issue out; which is the opium, and which, being of a glutinous nature, will adhere to the bottom of the incision; but some poppies are so productive, that it will drop from the pod on the leaves underneath. The next day, if the weather should be fine, and a good deal of sunshine, the opium will be found a greyish substance, and some almost turning black: it is then to be scraped from the pods, and (if any there) from the leaves, with the edge of a knife, or other instrument for that purpose, into pans or pots; and in a day or two it will be of a proper consistence to make into a mass, and to be potted.

According to Mr Ball, fields cannot be sown with any thing more lucrative to the farmer than poppies, especially if those fields have a south exposure. "By a calculation (says he) which I have made, supposing one poppy to grow in one square foot of earth, and to produce only one grain of opium, more than L. 50 will be collected from one statute acre of land; but if we consider, that one poppy produces from three or four to ten heads, that in each head from six to ten incisions may be made, and that from many of them (I mean from one incision) I have taken away two or three grains of opium—What must then be the produce?"

Mr Ball produced to the Society letters from Dr Latham of Bedford-row, Dr Pearson of Leicester-square, and Mr Wilson of Bedford-street, declaring, that, in their opinion, his English opium is equal in effect, and superior in purity, to the best foreign opium.

OPTIC INEQUALITY, in astronomy, is an apparent irregularity in the motions of far distant bodies; so called, because it is not really in the moving bodies, but arising from the situation of the observer's eye. For if the eye were in the centre, it would always see the motions as they really are.

OPTIC *Pyramid*, in perspective, is a pyramid formed by the visible object which is the *base*, and the rays drawn from the perimeter of that object, which meet at the eye in a point, which is the *apex* of the pyramid. Hence, also, we may know what is meant by an *optic triangle*.

OPTIC *Rays*, particularly means those by which an optic pyramid, or optic triangle, is terminated.

ORAN, a considerable city, occupied by the Spaniards, in the province of *Mascara*, in the country of Algiers. It has strong and regular fortifications, and can easily be supplied from Spain with provisions and warlike stores. It lies in 35′ of longitude west from Greenwich, and in 35° 55′ north latitude. Since the year 1732, the Spaniards have held uninterrupted possession of Oran. It has a parish-church, three monasteries, an hospital: and the number of the inhabitants, according to the account given of it by the Spaniards, amount to 12,000. Towards the sea, the city rises in the form of an amphitheatre, and is surrounded with forts and batteries. Close to the city lies a strong castle, *Alcazava*, in which the Spanish governor resides. On the highest hill stands Fort St Croix, whose guns command the city and the adjacent country. From this fort they make signals of the approach of ships, and carefully watch the motions of the Moors, who often attempt predatory incursions into the neighbouring districts. A considerable number of Mahomedans take refuge in Oran; they dwell in a distinct part of the city, receive pay from the court of Spain, and render signal services against the Moors. The greatest part of the inhabitants of Oran consists of such as have been banished from Spain; and the same may, in a great measure, be said of the soldiers who compose the garrison. Five regiments are commonly stationed here; but, owing to continual desertion, their strength scarcely equals that of four complete regiments. One of them wholly consists of malefactors, who have been condemned to remain here for life; the rest are such as have been transported for one or more years. There is here likewise a military school. Around the city are pleasant gardens; but it is very dangerous to cultivate them, on account of the Moors and Arabs, who frequently lie in ambush among them. The same reason prevents the cultivation of the fields in the vicinity; and the garrison

fon and inhabitants muft be fupplied with provifions immediately from Spain.

ORANGE-MEN, an appellation affumed by certain focieties in Ireland, of which the firft was formed in the county of Armagh, on the 21ft of November 1795, others in fome towns of Ulfter and Leinfter in the year 1797, another in the city of Dublin 1798; and fince that period, thefe focieties have fpread over the whole of our fifter kingdom. The object of thefe affociations is exhibited in the following authentic *Declaration of the Principles of Orange-men*, publifhed 1799.

"From the various attempts that have been made to poifon the public mind, and flander thofe who have had the fpirit to adhere to their king and conftitution, and to maintain the laws:—

"We, the Proteftants of Dublin, affuming the name of Orange-men, feel ourfelves called upon, not to vindicate our principles, for we know that our honour and loyalty bid defiance to the fhafts of malevolence and difaffection, but openly to avow thofe principles, and declare to the world the objects of our inftitution.

"We have long obferved, with indignation, the efforts that have been made to foment rebellion in this kingdom, by the feditious, who have formed themfelves into focieties, under the fpecious name of *United Irifh*.

"We have feen with pain the lower orders of our fellow-fubjects, forced or feduced from their allegiance, by the threats or machinations of *traitors*.

"And we have viewed with horror the fuccefsful exertions of *mifcreants*, to encourage a foreign enemy to invade this happy land, in hopes of rifing into confequence on the downfal of their country.

"We therefore thought it high time to rally round the conftitution, and there pledge ourfelves to each other, to maintain the laws, and fupport our good king againft all his enemies, whether *rebels* to their God or to their country; and by fo doing, fhew to the world that there is a body of men in this ifland, who are ready, in the hour of danger, to ftand forward in defence of that grand palladium of our liberties, the conftitution of Great Britain and Ireland, obtained and eftablifhed by the courage and loyalty of our anceftors under the Great King William.

"Fellow-fubjects, we are accufed with being an *inftitution*, founded on principles too fhocking to repeat, and bound together by oaths, at which human nature may fhudder: but we caution you not to be led away by fuch malevolent falfehoods; for we folemnly affure you, in the prefence of the Almighty God, that the idea of injuring any one, on account of his religious opinion, never entered into our *hearts*: we regard every loyal fubject as our friend, be his religion what it may; we have no enmity but to the enemies of our country.

"We farther declare, that we are ready, at all times, to fubmit ourfelves to the orders of thofe in authority under his majefty, and that we will cheerfully undertake any duty which they fhall think proper to point out for us, in cafe either a foreign enemy fhall dare to invade our coafts, or that a domeftic foe fhall prefume to raife the ftandard of rebellion in the land. To thefe principles we are pledged—and in fupport of them we are ready to fpend the laft drop of our blood.—(Signed) Thomas Verner, *Grand Mafter*; John Clau. Beresford, *Grand Secretary*; William James, J. De Joncourt, Edward Ball."

Orchard.

ORCHARD. As an appendix to this article in the *Encycl.* fome of our readers will be pleafed with the following means, employed by the Rev. Mr *Germerfhaufen*, for promoting the growth of young trees, and increafing the fize and flavour of the fruit in orchards.

Having planted feveral young plum trees in an orchard, he covered the ground, for fome years, around the trunks, as far as the roots extended, with flax-fhows (A); by which means thefe trees, though in a grafs-field, increafed in a wonderful manner, and far excelled others planted in cultivated ground. As far as the fhows reached, the grafs and weeds were choaked; and the foil under them was fo tender and foft, that no better mould could have been wifhed for by a florift.

When he obferved this, he covered the ground with the fame fubftance, as far as the roots extended, around an old plum-tree, which appeared to be in a languifhing ftate, and which ftood in a grafs-field. The confequences were, that it acquired a ftrong new bark; produced larger and better-tafted fruit; and that thofe young fhoots, which before grew up around the ftem, and which it was every year neceffary to deftroy, were prevented from fprouting forth, as the covering of flax-fhows impeded the free accefs of air at the bottom of the trunk.

In the year 1793, he tranfplanted, from feed-beds, into the nurfery, feveral fruit-trees; the ground around fome of which he covered, as above, with flax-fhows. Notwithftanding the great heat of the fummer, none of thofe trees where the earth was covered with fhows died or decayed; becaufe the fhows prevented the earth under them from being dried by the fun. Of thofe trees, around which the ground was not covered as before mentioned, the fourth part mifcarried; and thofe that continued alive were far weaker than the former.

The leaves which fall from trees in autumn may alfo be employed for covering the ground in like manner; but ftones, or logs of wood, muft be laid on them, to prevent their being difperfed by the wind. In grafs-land, a fmall trench may be made around the roots of the tree, when planted, in order to receive the leaves. If flax fhows are ufed, this is not neceffary; they lie on the furface of the ground fo faft as to refift the force of the moft violent ftorm. The leaves which our author found moft effectual in promoting the growth and fertility of fruit trees, are thofe of the walnut tree. Whether it is, that, on account of their containing a greater abundance of faline particles, they communicate manure to the ground, which thereby becomes tender under them; or that they attract nitrous particles from the atmofphere; or that, by both thefe means, they tend to nourifh the tree both above and below.

Thofe who are defirous of raifing tender exotic trees from the feed, in order to accuftom them to our climate, may, when they tranfplant them, employ flax-fhows with

(A) Shows are the refufe of flax when it is fcutched or heckled.

with great advantage. This covering will prevent the frost from making its way to the roots; and rats and mice, on account of the sharp prickly points of the flax shows, will not be able to shelter themselves under them.

ORCHILLA, a weed used in dyeing, which grows in the Canary islands, and is monopolized by the government. "It is a minute vegetable (says Sir George Staunton), of the lichen kind, growing chiefly upon rocks of a loose texture, and produces a beautiful violet blue colour."

ORDEAL. See this article in the *Encyclopædia*, at the end of which we have given, from Dr Henry's History of England, some strong reasons for suspecting that the ordeal, by fire at least, was a gross imposition on the credulity of an ignorant and superstitious age. This suspicion of imposture is raised to certainty by Professor Beckmann, who, in his History of Inventions, gives us the whole process by which the clergy conducted the trial, and brought proofs of innocence or of guilt at their pleasure. The person accused was put entirely under their management for three days before the trial, and for as many after it. They covered his hands (when he was to lift red-hot iron) both before and after the proof; sealed and unsealed the covering. The former was done, as they pretended, to prevent the hands from being prepared any how by art; the latter, that it might be accurately known whether or not they were burnt.

Some artificial preparation was therefore known, else no precautions would have been necessary. It is highly probable, that during the three first days the preventative was applied to those persons whom they wished to appear innocent; and that the three days after the trial were requisite to let the hands resume their natural state. The sacred sealing secured them from the examination of presumptuous unbelievers: for to determine whether the hands were burnt, the three last days were certainly not wanted. When the ordeal was abolished, and this art rendered useless, the clergy no longer kept it a secret. In the 13th century, an account of it was published by Albertus Magnus, a Dominican monk (A). If his receipt be genuine, it seems to have consisted rather in covering the hands with a kind of paste than in hardening them. The sap of the *althæa* (marshmallow), the slimy seeds of the flea-bane, which is still used for stiffening by the hat-makers and silk-weavers, together with the white of an egg, were employed to make the paste adhere. And by these means the hands were as safe as if they had been secured by gloves.
